It is a well-known fact that two stages of ordinary audio-frequency is generally looked upon as the reasonable limit to take that type of amplification. The reason that this point has been so fixed by custom is owing to the fact that when more than two stages have been employed all sorts of distortion is encountered. In fact, with some transformers a third stage of audio-frequency so distorts the music and voice that the reception is rendered wholly useless. The solution to the problem is the employment of push-pull amplification instead of the ordinary type of amplification for the second or third stages. It has been found that one stage of straight amplification and then one stage of push-pull type as explained in this article will render wonderful results in quality and volume. It is a well-known technical fact that the push-pull system of tube amplification will render more volume and quality than an equal number of tubes placed or connected in the ordinary method of transformer amplification. Then, again, the development of the new C-301A and UV-201A tubes has made it possible to design push-pull amplifiers that work satisfactorily without the use of power tubes. This is a great item for the summer vacationist who would find it rather inconvenient to lug around storage batteries and the large supply of "B" batteries such tubes required to work efficiently. With these new tubes dry cells can be used for filament lighting and if the amateur so desires he can use a smaller storage battery than he would need if large power tubes had been used. In addition he will find that two small 45-volt "B" batteries will last him many months more than the summer season. This style of amplifier can be used with or without one or more stages of straight amplification by means of the ordinary transformers.

The general schematic connections are clearly shown in the illustration herewith. Two push-pull types of transformers are used. A "C" or grid bias battery of 4.5 volts is recommended when UV-201A tubes with 90 volts plate potential are employed in the circuit. A separate rheostat is furnished for each tube in order to make it possible to adjust the two tubes to the same operating point on their characteristics. The method of adjustment is to remove one tube from the amplifier and adjust the remaining one for maximum volume Then replace the other and remove the first tube, and repeat the operation until the same amount of volume is heard. The adjustment is effected by the control of the filament rheostats to each tube. After these adjustments have been made both tubes can be placed in the sockets and the amplifier is ready for operation. These rheostat settings should not be changed and the amount of volume should be varied either by turning down the detector or a previous tube in another stage of amplification. Of course, if the volume continues to remain too high for all occasions then another adjustment can be made, but for just momentary changes in volume it is better to accomplish the same as previously explained.

Now comes the "where to buy" situation. The tubes, rheostats, sockets, and batteries are indeed quite easy to procure, but the purchase of the desirable transformers for push-pull work cannot so easily be manipulated. After you look around a little, I shall be very glad to assist any one in finding a place where the transformers can be accurately made to order at a most reasonable cost, about $12.50 for the pair. If you should desire to write me concerning this, address me in care of RADIO WORLD, enclosing a self-addressed envelope with your letter, and I will see that your letter is forwarded to the right party. I wish fully to emphasize the fact that this is by no means a marketing scheme, because if you are able to get what you want in your home town it is much better in many ways that you patronize your favorite dealer. Let me again emphasize the fact that this complete outfit can be readily built for less than $50, and the cost for an amplifier working on the same principle would cost many times that figure. When you first use this type of amplification you will be more than surprised at the amount of volume without distortion that can readily be obtained from two tubes. It is indeed a great pity that many amplifiers built upon this type are not in more common use. It is often the case that the distortion that we are so wont to blame on the loud speaker in reality originates in the amplifier. Please note the fact that with this style of circuit the direct current plate potential supply does not in any way pass through the loud speaker windings. This fact not only means less distortion, but also means that the loud speaker winding is fully insulated from high voltage and burn-outs resulting from short circuiting the same through the coils.

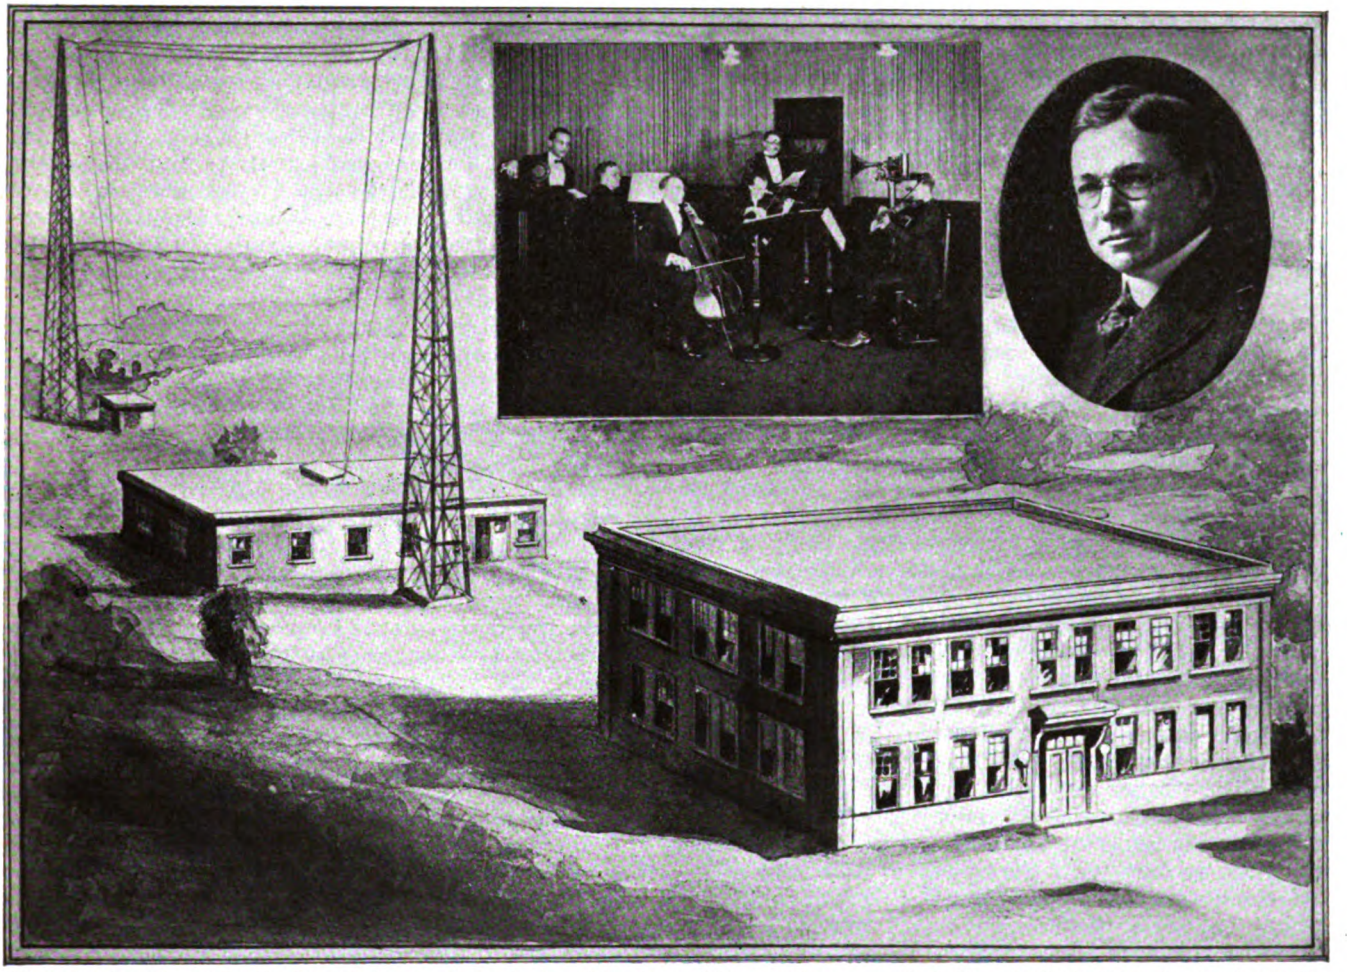
A New Pacific Coast Broadcasting Station

By C. H. Huntley

FAITH in the permanence of radio broadcasting is demonstrated by the announcement of the General Electric Company that the first plant to be constructed exclusively for popular broadcasting will be erected in Oakland, California, to house the large Pacific Coast station of that company.

Work will be started this month on a two-story studio building, the antenna towers and the power house. Workmen are already assembling the radio equipment. It is expected that the new station will be on the air within six months.

and quarters for motor-generator sets and storage batteries. There will be two studios on the second floor, the main studio large enough to accommodate large bodies of musicians such as a band or symphony orchestra, and a smaller studio from which solo numbers and addresses may be broadcast. The use of two studios will make possible continuous broadcasting. Research is now being carried on to determine the reverberating qualities of the ideal studio in order that the proper amount of dampening may be secured in the Oakland studio to assure maximum musical quality. The radio control room will be on the second floor.



Wash drawing of new Pacific Coast Radio Broadcast Station of the General Electric Company to be built at Oakland, California, showing studio and office building, power station and antenna. Insert in center shows how the studio will look and to the right is a portrait of Martin P. Rice, Director of Broadcasting of the General Electric Company.

Martin P. Rice, director of broadcasting for the General Electric Company, will direct the operating policy of the station and Dr. Thomas Addison, manager of the company's interests on the Pacific Coast for the past thirty years, will have supervision of the plant.

The station will be located on East 14th Street, Oakland, adjacent to the new General Electric Company factory building. The site was selected after a thorough inspection of available properties in San Francisco and vicinity. The Oakland plot was chosen because of its technical advantages, the availability of musical talent, and the proximity of the site to San Francisco, the great commercial center of the Pacific Coast.

The plans provide for a two-story brick structure. On the first floor will be the office of the studio manager, a general correspondence room, a reception room for artists

One thousand feet back of the studio building will be the power house and antenna system. The antenna will be multiple-tuned and strung between two steel towers, each 150 feet high and placed 260 feet apart. Beneath the antenna proper will be the counterpoise consisting of a network of wires, fourteen feet above the ground, covering an area of 150 to 300 feet. In addition to the power house, which will be one story high, 71 by 32 feet, there will be a small building for the tuning apparatus and the end of the multiple-tuned antenna.

The transmitting set will be similar to that which is now heard almost nightly from WGY, Schenectady, N. Y., and the many developments which have brought this station a reputation for exceptional transmission quality will be part of the Pacific Coast station equipment. The apparatus is

The Interdepartment Radio Advisory Committee Organized for the Government

THIS committee had its origin in the First National Radio Conference called by Secretary of Commerce Herbert Hoover which met from February 27 to April 19, 1922. In connection with the assigning of wave length bands for government radio broadcasting it became apparent that there would have to be agreement among the government departments as to the use and distribution of the wave lengths in the government bands. A certain amount of broadcasting was being done by several departments, with little or no co-ordination. An extensive daily program of broadcasting market and crop reports was being transmitted for the Department of Agriculture by seven continuous-wave stations of the Post Office Department. This development was begun in December, 1920. Weather reports and hydrographic news have been broadcast from 30 radio telegraph stations of the Navy Department since 1905. Broadcasting was being done in an experimental way by some other government stations.

On April 24, 1922, Secretary Hoover invited each of the ten Departments of the Government to name a representative on a permanent committee to co-ordinate the radio broadcasting of the Government. As the Chief Co-ordinator, Bureau of the Budget, had also drawn up a plan for a co-ordinating radio committee, a representative of the Chief Co-ordinator was added. Subsequently representatives of the Shipping Board and the Interstate Commerce Commission were added. Thus the committee now includes representation from every part of the government that has any substantial interest in radio.

In the beginning the committee dealt only with broadcasting. Various problems arose which indicated the desirability of extending the scope of the Committee to include a wider field than radio broadcasting. On December 15, 1922, the committee voted to recommend to the Secretary of Commerce that he take action to extend the scope of the committee to include all matters of government radio communication. This was done by the Secretary of Commerce with the concurrence of all the other departments. The scope of the committee's activities was stated by the Secretary of Commerce in his letter of January 5, 1923, to the other departments, to be "with the approval and participation of the interested departments, to cover matters pertaining to radio communication in general. The functions of the committee are to remain purely advisory....to all the participating departments in matters coming under its cognizance."

The chairman of the committee is Acting Secretary S. B. Davis of the Department of Commerce, who serves as the representative of that department on the committee. The committee membership also includes representatives of the following departments and independent establishments: Department of Agriculture, Bureau of the Budget, Office of Chief Co-ordinator; Department of the Interior, Interstate Commerce Commission, Department of Justice, Department of Labor, Navy Department, Post Office Department, U. S. Shipping Board Emergency Fleet Corporation, State Department, Treasury Department, War Department.

The committee has the following standing subcommittees: Subcommittee on Material for Broadcasting, Subcommittee on Operating Procedure, Subcommittee on Technical Problems, Subcommittee on Mobile Radio, Subcommittee on Government Radio Policy and Legislation.

The committee began in 1922 an experimental system of "primary" broadcasting stations for the transmission of official government news by continuous-wave (code) telegraphy, this news being available to approve privately owned broadcasting stations for re-broadcast by radio telephone. Use has been made solely of previously existing stations. Seven Post Office Department (Air Mail) stations were used at the outset and have been replaced by the following navy stations, working on frequencies between 50 and 65 kilocycles (between 6,000 and 4,600 meters); Arlington, Va., Great Lakes, Ill., New Orleans (Algiers), La., San Francisco, Cal. These primary stations accomplish the same purpose as leased wires in supplying material to the radio telephone broadcasting stations.

There is one government radio telephone broadcasting station, that at Arlington, Va. Its frequency, under the new assignments, is 690 kilocycles (435 meters). It broadcasts lectures, market news and miscellaneous information, supplied by the Departments of Agriculture, Commerce, Interior, Labor, and Treasury, and also music by government bands. The schedule includes eighteen 15-minute periods of radio telephone broadcasting daily.

The character of material, schedules, and procedure for both primary and radio telephone broadcasting are approved by the Interdepartment Committee. About 100 privately owned broadcasting stations are supplied with material from several Departments and authorized to broadcast it by radio telephone.

It is impossible to state the cost of broadcasting by government departments because such operations have been conducted in connection with the other regular radio work of the departments. The figures given here represent simply an apportionment of cost or additional cost to the departments concerned. The cost of conducting the broadcasting by government stations during the past year included $13,800 for equipment at navy stations (including installation, alterations, power and renewals). There was no equipment charge against broadcasting by the Post Office Department stations; the operation cost at the Post Office Department stations was approximately three cents per word. The average cost of the broadcasting from all seven Post Office stations for one day on a fifteen-hour basis was $53.93. This was 19% of the total cost of operating the Air Mail stations and amounted to $16,826 per year. The committee has no estimate of the operation cost of the broadcasting from navy stations, nor of the cost of preparing the material in the departments furnishing the material.

The committee has carefully considered the classification of material for broadcasting. The committee has adopted the principle that radio broadcasting should not be used where wire telegraphy or telephony or printed publication would be as satisfactory.

One of the chief functions of the committee is coordinating the services and equipment of the radio stations operated by the several departments. The committee has made a complete survey of the equipment and service of all these stations and has assigned new frequencies (wave lengths) to them to accord with the recommendations of the Second National Radio Conference. The committee's work is bringing about more uniformity in types of equipment used.

The several departments feel that the committee has been a satisfactory clearing-house for government

Simple and Easily Made Neutrodyne Condensers

By J. E. Anderson

EVER since Prof. Hazeltine introduced his neutrodyne receiver there has been a demand for small variable condensers that may be used in the construction of such receivers. None of the ordinary vernier condensers on the market has a capacity sufficiently small to meet the demand, as their minium capacity is approximately what the maximum should be for neutrodyning the ordinary amplifier. The capacity required is of the order of one micromicrofarad.

Two wires placed near each other without touching form a condenser of very small capacity. If they are at right angles to each other the capacity is minimum and if they are parallel it is maximum. The capacity may either be varied by turning one with respect to the other or by varying the distance between them. It may also be varied by varying the length of the parallel portion. One of the simplest variable condensers of the parallel wire type is obtained by twisting two insulated wires together. The capacity is increased or decreased by twisting or untwisting the wires. The insulation of this wire should not be too thick or it would be required to twist too much wire together to obtain sufficient capacity. Enameled or silk covered wire is suitable. The capacity of such a condenser may be calculated, but the formula is too complicated for easy application and the right amount is found much more readily by trial. A pair of No. 20 double silk covered wires would have a capacity of about one-tenth micromicrofarad per inch.

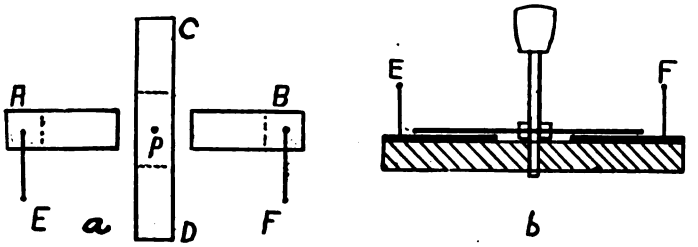

Fig. 1. Diagrams showing how a simple variable neutrodyne condenser can be made. Full instructions are given in the accompanying text.

Another condenser that may be easily constructed is shown in Fig. 1. A and B are metal plates or pieces of foil securely fastened to a base of insulating material. CD is a movable metal plate or vane capable of turning about the pivot P. The plan for the condenser set for minimum capacity is shown in *a* and a section of it when set for maximum capacity is shown in *b*. If the effective width of the stationary plates and the moving vane is ½ inch and the effective length when fully engaged is 1 inch, the capacity as measured between the points E and F is approximately 3.6 micromicrofarads for a separation between the plates of 1/64 inch. It will be noticed that there are really two condensers in series and the total capacity is one-half that obtained by calculating one side. A condenser of this type has no sliding contacts and the dielectric is air. Furthermore it will not easily short-circuit, as if one side touches the other will probably be farther away.

In Fig. 2 is shown a condenser that requires a little more work to build but that will present a much neater appearance when completed. Two brass bars AB are securely fastened to an insulating base BB, preferably hard rubber, and are drilled and tapped to admit a couple of ordinary switch points P. One of these is fixed in a convenient position and the other is made movable by turning the knob K. If switch points with quarter inch heads are used, the capacity of the condenser when the plates are separated .005 inch is approximately two micromicrofarads. If a greater maximum capacity than this is required, small metal disks of the proper diameter may be soldered to the switch points. But these disks must be perfectly flat and must be mounted concentrically with the screw and at right angle to its axis. The drilling of the bars AB and the mounting of the switch points on these supports must be done very accurately to prevent wobbling of the plates. It is best to give the plates a coat of shellac or some other insulating covering to prevent short circuit when the plates are close together.

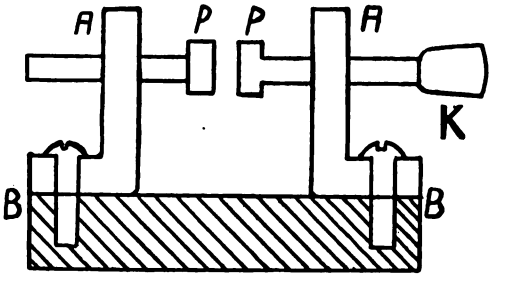

Fig. 2. Another type of neutrodyne condenser which can be constructed by the amateur desiring extremely small capacities.

A condenser of this type is capable of extremely fine variation in capacity. Its capacity is comparatively large when the plates are close and its rate of change with turning the screw is rapid. When the plates are far apart the capacity is almost negligible.

(*Concluded from preceding page*)

radio matters. While the experimental broadcasting system has operated fairly satisfactorily to date, the experience which has been had with it should be used as a basis of a rational plan for a government broadcasting system. The question is, of course, intimately related with the existing and prospective privately owned broadcasting stations throughout the country. If radio is to become of maximum benefit to the people, the government must continue to study the question of properly organized radio broadcasting and other services. There are constant occasions for curtailments or extensions of the government's radio plant, and the committee's effort is to co-ordinate these needs and fulfill them with maximum economy.

The committee has functioned successfully as a body advisory to the Secretary of Commerce and to the other departments. There have been no disagreements for which a solution has not been found. The committee has been the means of bringing together the diverse needs and interests of the several departments, and has attained a recognized standing in the government administration of radio matters. It should, eventually, be able to establish an efficiency acceptable to taxpayers.

Broadcasters Now Number 592

By Carl H. Butman

WASHINGTON, D. C.—Radio broadcasting stations total 592, according to the latest Department of Commerce survey. Of this number 113 are Class A stations, 36 highpowered Class B stations*, One—KDKA—designated as a broadcasting development station and the balance, 442, Class C operating on 360 meters.

Many old stations grouped temporarily as Class C and directed to operate only on 360 meters, have been reclassified as A stations and assigned special district waves. There remain 442 in this class either awaiting new wave lengths or satisfied to continue on 360 meters. New stations, however, are still coming in, about 30 being added in the last thirty days while 20 dropped out.

During the past week, four new A stations were licensed; one each in Pennsylvania and South Dakota, and two in Colorado. Fourteen C stations were transferred from Class C during the week ending May 26th.

*Note—See list of B stations in RADIO WORLD for May 14.

Four New Class A Stations Licensed

Call	Station	Frequency Kcys.	Wave Length Meters	Power Watts
WBBD	Barbey Battery Service, Reading, Pennsylvania	1,280	224	50
KFKH	Denver Park Amusement Co., Lakeside, Colo.	1,330	226	10
KFIJ	Thorean, Sidney I., Platte, S. D.	1,270	236	5
KFJD	Weld County Printing & Pub. Co., Greeley, Colo.	1,270	236	100

Fourteen Stations Transferred from Class C to Class A

Call	Station	Frequency Kcys.	Wave Length Meters	Power Watts
KDZF	Automobile Club of Southern California, Los Angeles, Cal.	1,080	278	500
WAAF	Chicago Daily Drovers Journal, Chicago, Ill.	1,050	286	200
KFZ	Doerr Mitchell Elect. Co., Spokane, Washington	1,060	283	5
WAAK	Gimbel Bros., Milwaukee, Wis.	1,070	280	100
WLAX	Greencastle Community Broadcasting Station, Greencastle, Ind.	1,300	231	5
WLAZ	Hutton & Jones Elect. Co., Warren, Ohio	1,210	248	10
WIAK	Journal Stockman Co., Omaha, Neb.	1,080	278	200
WEAG	Nichols Hineline Bassett Lab., Edgewood, R. I.	1,300	231	10
WIAD	Ocean City Yacht Club, Ocean City, New Jersey	1,180	254	10
WMH	Precision Equipment Co., Cincinnati, Ohio	1,210	248	10
WQAS	Prince Walter Co., Lowell, Mass.	1,130	266	100
WHAQ	Semmes Motor Co., Washington, District of Columbia	1,240	242	10
WMAP	Utility Battery Service, Inc., Easton, Pennsylvania	1,220	246	50
WQAD	Whiteall Electric Co., Waterbury, Connecticut	1,240	242	50

Broadcasters Deleted During May

The following 20 stations were deleted from the lists of active broadcasting stations by the Department of Commerce during May:

Class A

KFGM—Abilene Daily Reporter, Abilene, Texas.
KFHC—University of Oklahoma, Norman, Okla.

Class C—360 Meters

KYI—Bakersfield Californian, Bakersfield, Cal.
KFGE—Buchanan Stevens Co., Mt. Vernon, Wash.
WWAJ—Columbus Radio Club, Columbus, Ohio.
WAAJ—Eastern Radio Institute, Boston, Mass.
WEAT—Fogarty, J. J., Tampa, Fla.
KFV—Foster-Bradbury Radio Store, Yakima, Wash.
KDZH—Fresno Evening Herald, Fresno, Calif.
WDAC—Illinois Watch Co., Springfield, Ill.
WFAU—Lewis, Edwin C., Inc., Boston, Mass.
KDN—Meyberg, Leo J., Co., San Francisco, Calif.
KYJ—Meyberg, Leo J., Co., Los Angeles, Calif.
WGAH—New Haven Electric Co., New Haven, Conn.
WHAR—Paramount Radio & Electric Co., Atlantic City, N. J.
WPAW—Radio Installation Co., Wilmington, Del.
KQY—Stubbs Electric Co., Portland, Oregon.
KFAZ—Weatherill, C. H., Reedley, Calif.
WJZ—Westinghouse Elec. & Mfg. Co., Newark, N. J. (Transferred to "Broadcast Central," New York City.)
WPM—Williams, Thomas J., Washington, D. C.

U. S. S. "Wyoming" Equipped For Duplex Radio Communication

HIGHLY gratifying results have been secured with a new model high-power tube transmitter installed on the battleship "Wyoming," and used in regular traffic. "In fact," states a Naval report, "some results were unexpected, such as ability to receive on the same vessel during full power operation of this tube rating about 5 KW." Numerous broadcasting stations transmitting on 400 meters were tuned-in in the auxiliary radio room, while the big transmitter, installed in the main radio room, was supplying 36 amperes to the main antenna on a wave length of 507 meters. The receiving set in the auxiliary room was equipped with an amplifier consisting of three stages of radio-frequency and two stages of audio-frequency. "This condition allows duplex communication, which has actually been put in practice on the Wyoming and will be further developed on the 'Colorado' and 'West Virginia,'" the report states.

The arrangement of the radio rooms on these two battleships will differ from present naval practice. Receiving will be done in the main receiving room forward and transmission will be carried on aft from the main transmitting room.

In Naval Aviation Squadrons new tube sets are also replacing spark sets. Five new aerial spotting sets have passed satisfactory tests and are en route to the Air Squadrons of the Battle Fleet, where they will replace SE 1345 sets now in use. Spark sets will be used only at Pensacola for training Naval radio personnel.

Swat the Birdies! How to Minimize Re-Radiation

By Anderson James

THE rapid increase of "birdies" that swarm the ether is becoming a menace to successful radio reception. You can hear their chirps and tweets from every housetop. They light on your antenna and proceed to gargle their throats in the very midst of an operatic selection. They caw and groan and growl and squawk and sputter. And there is no way of scaring them off their perch. At such times there is a strong temptation to the average listener to desert the legitimate vocabulary and indulge in bootleg words. A remedy for the nuisance has been suggested by momentarily converting your receiving set into a transmitter and directing these words to the offender-in-chief. But chances are that he would be out of tune and would miss the message entirely, and the only effect would be to increase the suffering of the innocent bystander. Before you proceed to exact satisfaction be sure that you are not one of the offending birdie breeders. Remember that your neighbor's antenna is not a scarecrow, but it will attract the birdies you let loose as rapidly as your own. They will perch upon it and squirt their unmelodious gamuts into the listener's ears until he tears the phones off his head and condemns the whole radio game.

Let us declare an open season on the birdies. Swat them unmercifully. A little co-operation among the neighborhood birdie victims, and some radio detective work on their part, will readily locate the persistent birdie breeder. He should then be warned that his set is disturbing the neighborhood and, if he persists, his name should be posted or published for maintaining a public nuisance.

There is only one way in which this trouble may be completely eliminated and that is to prevent the receiving set from oscillating. But it is practically impossible to prevent a regenerative circuit from oscillating while tuning in if it is to work anywhere near its maximum efficiency; and the general use of non-regenerative sets can hardly be expected. It therefore remains to minimize re-radiation as much as possible. There are many ways of doing this.

One of the simplest is to detune the antenna circuit by three or more kilocycles from the frequency of the signal desired and depend on the selectivity of the secondary tuned circuit for signal strength. Since the antenna is not tuned to the incoming signals, local oscillations of about the same frequency cannot take place in it with any great intensity, and when they do take place the beat frequency will be too high to cause much interference.

Another method is to reduce the coupling between the primary and the secondary and between the primary and the tickler. There is no advantage in increasing the coupling beyond a certain point except where broadness of tuning is the object. In Fig. 1 is shown a curve representing the amount of energy transferred from the primary to the secondary when both are tuned to the same frequency. It is noticed that the current in the secondary at first increases very rapidly with an increase in the coupling but finally reaches a maximum point. Beyond this the current actually decreases and it is of no advantage to increase the coupling any further. The tickler coil should be so placed with respect to the antenna that the coupling is minimum and yet retain the desired coupling between the grid and plate circuits. The tickler may be wound on the same form as the secondary and the amount of regeneration varied by means of a series condenser, a variable resistance, or an inductive coupling elsewhere in the circuit. Then the coupling between the antenna and the secondary may be reduced without increasing the amount of re-radiation, as the coupling between the tickler and the antenna is also reduced. Either the primary or the secondary may be on the stator, but it will simplify wiring to put the antenna on the rotor and vary its inductance by means of a loading coil.

Re-radiation may be reduced by introducing the feedback energy by means of a coil in series with the secondary tuned circuit as is exemplified in Fig. 2, and placing them so that their axes are at right angles. This method may also be used in a single circuit tuner, whereas the preceding two were only applicable to double circuits. However, the single circuit is usually the chief offender in producing "birdies" and should be avoided wherever possible. Advantage may be taken,

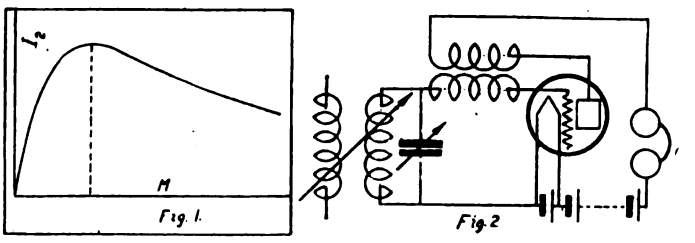

Diagram showing one method of decreasing re-radiation in a set.

however, of the greater range of the single circuit by using it as a non-regenerative amplifier followed by a regenerative detector or radio-frequency amplifier. This two tube circuit may be neutrodyned for better results.

The best non-regenerative circuit is undoubtedly a neutrodyne with tuned coupling between stages. If the neutrodyning has been properly done there is no back coupling from one stage to the preceding, and consequently there is no tendency to oscillate even when the successive stages are in exact resonance with the incoming signal and with each other. Therefore a regenerative detector may be used in connection with such circuit without danger of transferring sufficient energy to the antenna to cause appreciable interference with neighboring receivers. When, for economic and other reasons, it is not desired to use a multi-tube set, the best circuit is one of the simpler reflexes.

The chief source of birdies is the single circuit tuner in the hands of a DX-er with his mind in other states and his regard for the innocent bystander replaced by vanity. He sets his receiver into vigorous oscillation and then picks up the distant stations by the zero beat method. He squirts around the carrier from the remote station until he succeeds in identifying its call letters and off he goes to another carrier and repeats the performance. This he keeps up until Honolulu signs off for the night, and the result of his catch is a jumble of capital letters which he proudly labels "My Result of a Half Hour DX-ing with the New Squirt and Squawk Receiver."

No Need for Clicks, Roars, Shrieks and the Awful Scream of Interference

By Arthur S. Gordon

WOW! Listen to her squeal! No concert tonight with QRM full blast next door! Can't seem to find a quiet wave length anywhere. Wonder what makes all that racket? Doesn't sound like any one kind of hubbub, but like the 57 varieties of din one on top of the other. It's getting worse and worse!"

Such is the plaint of the radio amateur whose receiver is catching and amplifying every sound in the universe excepting the ones it should.

What is there to do? Lots of things. Noises in a receiving set are there because of some fault in the adjustment of one or more of the various instruments. The discord can be cleared out easily and intelligently by an amateur who knows the separate causes, and it is the purpose of this article to describe those causes and to offer simple remedies which will reduce their disturbances to a minimum.

There are two general classifications of noises in radio receivers, outside and inside. Outside annoyances are those over which the amateur has no immediate control, such as the re-radiation of a neighboring set, atmospheric, and interference between two nearby broadcasting stations. These noises may be described as hoots, screams, crackles, roars, and discords. Inside noises, on the other hand, are those which originate within the cabinet of the radio receiver. They can be eliminated, provided, of course, that the set is properly designed and wired and the vacuum tube or tubes are not defective. It very often happens that a tube will be imperfectly made and thus have peculiar jangles all its own. Inside noises range anywhere from a series of widely separated clicks to high, shrill notes, with howls, hisses, rasps and wheezes thrown in for variety. When the outside and inside combinations get together, they produce the intensified and irritating effect known as "hash."

The tumult of sounds peculiar to a single tube set are increased in volume but scarcely in variety by one or two stages of amplification, with the possible addition of an amplifier howl. Taking up the inside noises one by one, the most disturbing and yet the easiest annoyance of which to rid oneself is the "howl" a receiver sets up whenever the operator moves his hands to or from the tuning dials. This effect is known as "body capacity." It is sometimes so great as to prevent a receiver from working. Of it one radio enthusiast writes:

"Body capacity was so bad in my set that at times I had to stand in a certain position and in no other. If I moved a fraction of an inch in any direction the set would howl and I would not be far from howling myself. The cord was very sensitive and if I moved my hands toward it or touched the headset the signals were gone. Touching the dials with anything less than a ten-foot pole was out of the question."

This statement may sound like the first few lines of a patent medicine advertisement, but it is true, every word of it. The radio amateur who wrote it found that his trouble was in placing the headphones on the negative side of the "B" battery. He changed over, placed the phones between the "B" battery and the tickler coil, and has ever since lived in peace with himself and his neighbors.

There are other ways of getting rid of troublesome body capacity. Having the aerial lead go to the rotor of the variable condenser, for example, instead of to the stator, takes away some of the annoyance, but by far the best way is to shield the entire back of the panel, making sure that the metal or foil used for shielding is not only grounded but that it does not touch any of the instruments.

Discontented grid-leak complaints come next. The grid-leak—properly adjusted—is a blessing, but improperly adjusted, it is just the opposite. It may be either over or under adjusted. The noises it is father to range from a slow steady click heard all around the tuning dials to a high, shrill scream heard only at certain points. These noises, to say the least, interfere with the operation of the set. They are caused by the "make and break" of the tube oscillations as they are alternately passed and choked by an *insufficient* value of grid-leak.

The slow clicks mean that the leak resistance is too high. It should be cut down, therefore, until the high, shrill note is reached. At this point, the proper resistance has almost been reached. Cut it down just a trifle more, and the shrill note will enter the inaudible stage. Be careful here. If the resistance goes the least shade below the proper value, no noises will be heard, it is true, but no signals will either, although there will be plenty of spark signals and carrier wave whistles to egg you on.

You probably will notice, when you have the grid-leak adjusted very close to its ideal value, that a certain position of your tickler coil will produce a low harsh hum, something like that of a hoarse fog-horn. Stop here. This is about the practical limit of amateur adjustment. If you want to search for signals in that area, lower the filament current, step down the "B" battery, and this hum will disappear.

For convenience, it is best to have a variable grid-leak condenser, which can almost in a moment be adjusted to the "silent value" demanded by the particular requirements of your own tube.

Harsh, sandy or grinding noises in the phones, resembling mild atmospheric, are due either to tight coupling or defective batteries, A or B singly, or both at once. A hiss or roar is due to excessive regeneration. Amateurs continue to discover that far better results are obtained with a minimum of filament current than with a maximum. A loud metallic vibration, noticed particularly with the WD-11 tube when the table or the cabinet is tapped, is merely a physical demonstration. It is due to the too rigid mounting of the tube socket. Place it on soft rubber or felt and this objectionable noise will disappear.

A pretty medley of discord comes from a receiver that is not properly wired. A loud and persistent hum that refuses to be tuned out indicates either a wrong or broken connection. If you hear this hum the very first time you listen in, ten chances to one you have made a mistake in wiring. If you hear it after the set has performed satisfactorily for some time, look for a broken connection.

Sometimes when you are enjoying a 360-meter concert to the utmost, in butts a 200-meter amateur crazy-bent for election. Due to his nearness, he slops over his assigned wave length and ruins your concert. He can be shunted out by a rejector circuit such as often has been described in RADIO WORLD. This is simply

Radio and the Woman

By Crystal D. Tector

MORE family trouble laid at the door of radio—and probably inefficient domestic management. The daily papers record that the lure of radio crop reports, lectures, popular songs and bedtime stories is given as the cause for marital disaster in a petition by a Queensboro woman. She charges that the attractions of the wireless waves kept her husband up "far into the night, listening to the music and messages." And when he finally came to bed he kept her awake the rest of the night arguing about new sets and wiring problems, she asserts. Again I ask—why not two sets of head phones and joint conjugal enjoyment.

* * *

Friend Husband and I went to the movies the other evening. As a part of the program they had a very instructive film which showed, in picture form, the way in which a radio wave is generated, modulated, propagated, received, rectified and amplified. It was a very interesting film and it was explained in a thorough and easily understandable manner, by means of cartoons with moving lines showing each change in current or wave. After seeing it, F. H. remarked, "Holy Moses, who in the world would think that that can all happen within a pace of time less than a second!"

* * *

I think that this particular idea of visualizing popular scientific facts is excellent and should be exploited more. Just think of the many ways in which it could be done. Automobiles and electricity, and oh, so many other things that are a continual mystery to the lay mind could be explained. I once heard a professor lecture and he told the class that the best way to impress a thing indelibly was to show it to a person and let him photograph it on his mind. Well, there were a lot of wise people that went out of that little movie that evening with at least a faint idea of what happens when they are listening to a radio concert. I know I went home impressed with the immensity of it all and the complete mastery of the theory that the engineers at the research laboratories must have.

* * *

F. H. came home the other night loaded down with some boxes and bundles and funny looking parcels. He took them into the garage and locked the door. I, of course, was all questions and curiosity but it availed me not. He was as informative as a clam with a bad case of lockjaw. After supper he sneaked off and locked himself in the garage and wouldn't even let me take the car out. I had no intentions of going out, but merely wanted to satisfy my curiosity. He stayed out in the smelly old place until about 11 o'clock and then, locking the door very carefully, put the key in his pocket and went to bed. The next morning when he had gone to business I went inside the garage and found—whatever do you think? A radio set *in our car*. Well, I had been teasing him to take our vacation traveling around the country this summer and so, thoughtful boy, he had started to get everything ready, even to buying a loop set for the car. Won't we have fun?

(C. International Newsreel Photo.)

Miss Phyllis Blackman, of Ridgewood, Long Island, who claims to have built her own receiver and made many long distance records with it. The receiver is a three circuit tuner of the conventional type.

(*Concluded from preceding page*)

a single circuit tuner consisting of a coil of wire and a variable condenser, which is run from the aerial to the ground apart from the bulk of the receiver. When the rejector circuit is tuned to 200 meters, all signals coming in on that wave length will go immediately to the ground.

The gurgling, rough, distorted music you sometimes hear is largely due to re-radiation from nearby sets. For this there are several cures. These do not include a law, as in England, against receivers which oscillate excessively, but they do contain a caution directed to those operators, who, because of inexperience or thoughtlessness, allow their two or three tube sets to transmit annoying howls while they are hunting for a station. This method of tuning is known as the "beat-note method," and has been found to still persist in its disturbing qualities at distances up to 25 miles.

One cure for re-radiation (others are the use of non-radiating tubes or circuits) is in a new conception of tuning. There is no need to have your tubes oscillating while hunting for a station. While you are doing so, annoying whistles running up and down the scale are crossing and re-crossing the concert program of your nearest neighbors. Why not adopt and urge others to adopt a milder method of tuning in?

Adjust the filament control to a point which by practice you know to be satisfactory. That is to say, adjust it to that low point it invariably falls to in the end. Now move the tuning dials slowly. Instead of a shrill carrier whistle, or a sharp squeak, you will be surprised to hear music or a voice coming in without any of the preliminary warnings or noises so commonly associated with tuning in a station. If your filament current is slightly insufficient, you will hear a hollow or breathing sound, with a slight increase in the regenerative stir in your headphones. A slight turn of the rheostat will remedy matters in a case of this kind. You will become accustomed to this method of tuning and not only will you prefer it to the more violent beat-note method, but you will be conferring a favor upon your neighbors—to say nothing of the wear and tear you will save on your tubes.

By a complete understanding of what makes the noises in our set, we are enabled to increase its efficiency. The more sensitive a receiver is, the more it seems to be affected by the noise producing defects. Many amateurs decrease the filament current, or step down the "B" battery to cut out the howling and other annoyances. This is obviously not the thing to do. It neither remedies the causes of howling nor does it get the most out of a tube which is more than anxious, under proper control, to do its best—and do it silently if you operate it properly.

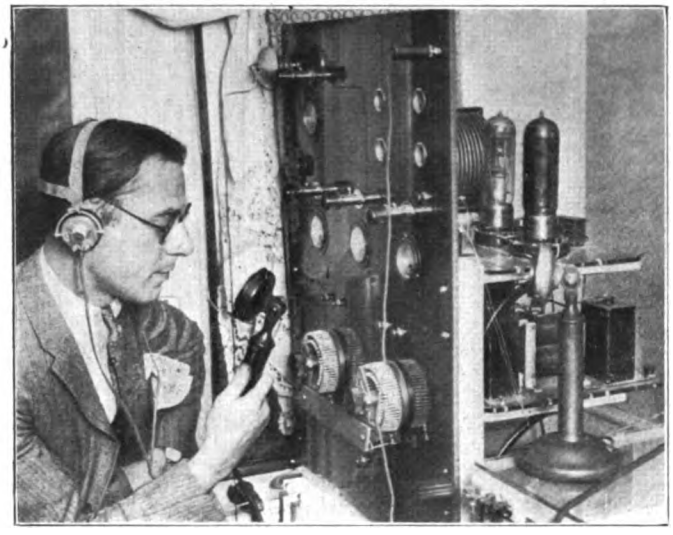
New York Amateur Owns $5,000 Station

By Earl Chatham

AN amateur station that lays claim and rightly so to being one of the finest equipped and most beautiful stations in the country, is Radio Station 2ABT, owned and operated by George Freisinger, a prominent New York amateur. From the standpoint of usefulness and workmanship, the station is the acme of perfection. From the standpoint of looks it is a beauty.

Referring to the illustration on the front cover, the extremely neat and efficient layout of the station can be seen. On the extreme left hand side of the table is the combined transmitter and receiving panel. On this is mounted the combined transmitter and the honeycomb coil receiver. The transmitter, which is a specially built machine, uses the Heising-Colpitts system of modulation and transmission. With this transmitter Cuban stations have been worked consistently. The transmitter is a 20 watt set, using two five watt oscillators, two five watt modulators, and one five watt speech amplifier. The amplifying transformers of the receiving system are also incorporated in the speech amplifying circuits, making three tubes in all as speech amplifiers. This is done through a special system of jacks which cut in on the receiving circuit, shortening the inductances and other apparatus and connecting up the amplifying circuits into the transmitting circuit. Either phone or CW can be used with this set and a distance of 1,800 miles has been consistantly covered.



(C. Kadel & Herbert)

100 Watt C. W. Transmitter at Station 2ABT. A complete view of the station is shown on the front cover of this issue.

Next to this cabinet, and in the smaller panel, is the Reinartz tuner with two steps of audio-frequency amplification. With either of these two sets the power amplifier can be used and horns are located through the entire house. By a system of jacks and plugs any one or a number of them can be plugged in at will.

For straight C. W. a 100 watt set is used, as shown in the smaller illustration on this page. Although constructed primarily for CW or buzzer modulation, it can be used with fair success as a phone set. The two 50 watt tubes are shown in the illustration, directly next to the tuning inductance.

The current for the operation of both of the sets is derived from a 1,000 volt generator of the airplane type. They are specially mounted and located in a noise proof cabinet in the main table of the set.

Every one of the units of this station were put to the most rigorous test before being combined in the final set which is shown, and then a special table was made to incorporate the different units.

Radiograms

Chas. R. C. Ham informs RADIO WORLD that a radio club has just been formed in Hong Kong, China.

* * *

Frank H. Shevit, income tax expert, will broadcast a series of short talks on the federal income tax from Station WJZ every Friday evening. Questions submitted by mail will be answered by radio.

* * *

British North Borneo has hundreds of thousands of acres suitable for the growing of rubber, according to Sir William Rycroft, Governor of that territory, who is visiting Manila, P. I. He said the Japanese have large concessions at Tawao, on the east coast of Borneo, where they have 20,000 acres planted to rubber.

* * *

Electric railways in the United States will spend the enormous sum of $240,000,000 for new equipment and plant facilities during 1923, according to a survey of expansion programs just announced by the Illinois Commission on Public Utilities. These proposed expeditures are about 60 per cent greater than those in 1922.

(*Concluded from page 7*)

now being manufactured in the Schenectady works of the General Electric Company and tested at WGY.

The Pacific coast station will be operated at 1,000 watts, but the equipment will be designed in excess of that power for purposes of conducting tests. In operating high-powered equipment below normal rating in broadcasting, tubes and rectifiers are not subject to occasional overloads, and, as a result, superior quality and greater reliability of transmission are obtained.

Six motor-generator sets will be placed in the power house and these will supply filament and plate current for the oscillator, modulator and kenetron rectifier tubes.

Every part of the equipment in the power house and in the control room will be in duplicate, assuring uninterrupted service. If one outfit or part of an outfit breaks down during the operation period another part will be ready to be brought into the circuit.

There will be six tubes in the kenetron rectifier assembly, one metal plate oscillator tube and one metal plate modulator tube. The control room in the studio building will have three stages of speech amplification made up of two 5-watt tubes and four 50-watt tubes. A fourth stage of speech amplification will be installed in the power house.

By means of what is known as "remote control" the facilities of a radio broadcasting station may now be brought to banquet hall, theatre or church and the audience, heretofore limited to the seating capacity of hall or church, is multiplied many times. The church is connected to the transmitting equipment by telephone lines and control of broadcast material is maintained in the church by operators.

The Pacific Coast station of the General Electric Company will utilize "remote control" to broadcast church services and musical entertainments from San Francisco and Oakland. The Pacific Telegraph & Telephone Company has offered to provide land wire connection.

Elementary Instruction for the New Army of Radio Beginners

Constantly Used Terms Explained in Plain Language for the New Radio Enthusiast

By Lynn Brooks

RE-RADIATION: This term, when applied to a receiver, means the circuit's ability to radiate a wave of its own origin. In regenerative or oscillating circuits, this wave changes in length with every change in the receiver, and it is due to this ability of a receiver that causes interference and "birdies" in other receivers. By correct design and placing of capacity and inductance this bug-bear of regenerative receivers can be eliminated, or a circuit may be attached or placed in relation to the tuning element of the receiver which will absorb the radiated wave and render the receiver incapable of putting the energy into the antenna.

* * *

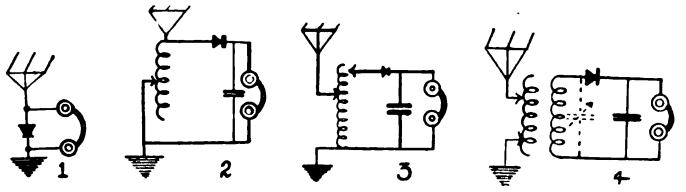
INSULATION: In all circuits carrying electricity some material must be used to prevent the electricity flowing in the line from leaking away, or finding a shorter path to its eventual destination by using another conductor. In order to accomplish this, insulation is used, which is any material that will not conduct electricity. The most common form of insulating material is rubber, both hard and soft. In its hard state it is used as panel, tubes and rod, and also as dials and different parts such as stators, rotors, etc. In its soft state it is used as tubing to cover wires. Bakelite and various other synthetic compositions are also used for the same purpose. Wood when dry is an insulator, even though a poor one, and while sometimes used for panels, it is not to be recommended.

* * *

COUPLING: In a receiving circuit there are two methods of coupling commonly used to transfer the signals from the antenna circuit to the detector circuit. The simplest and easiest method is to use conductive coupling. In conductive coupling the antenna and detector circuits are joined by means of wire, the tuning being accomplished by varying the inductance and capacity in the circuit, and therefore changing the frequency to which the circuit will respond. This method of coupling is used in all the single circuit sets. In these circuits the advantage is simplicity in both construction and tuning, as generally the circuit is tuned by either one or two controls, either of which contrals capacity, or inductance. In the second method, called inductive coupling, the antenna and detector or rectifying circuits are separate, the link between the two being the closeness or looseness of coupling used. In close coupling the secondary inductance is placed in such a manner that the windings are close together, and the electro-magnetic coupling is at its highest point. When this is the case, the signals in the detector circuit will be strong but the tuning will be broad, because of the fact that the electrostatic coupling is close. As the tuning is loosened, the coupling between the two circuits decreases and greater selectivity is obtainable. The advantage of using this type of tuning in a circuit is obvious, as the secondary circuit can be tuned independent of the primary circuit, and if there is more than one station transmitting at the same time, the one desired can be obtained with the least amount of interference from the second.

* * *

CIRCUIT: A combination of instruments connected in such a manner that they will either transmit an electro-magnetic wave or be capable of receiving or making audible to human ears the electro-magnetic waves of a transmitter. Receiving circuits are divided into various classes, depending upon the complexity of each one. The simplest receiving circuit possible consists of simply an antenna, detector, phones and ground as shown in Fig. 1. This is an untuned circuit and of the simplest form. No tuning can be done with this circuit and reception will only be possible on waves of the same length and period as that of its antenna. The simplest tuned circuit is that shown in Fig. 2. It consists of a single slide tuner, detector, fixed condenser, phones, antenna and ground. This is more selective than the preceding circuit. It can be tuned by moving the slider up or down the inductance and incorporating more or less wire in the circuit and therefore changing the wave length, or frequency, to which the circuit will respond. Fig 3 shows a two



Figs. 1-4. Diagrams illustrating simple crystal circuits, from the untuned to the inductively coupled set.

slide tuner circuit, incorporating the same apparatus as the preceding, with the exception of utilizing a two slide tuner instead of the single slide tuner. With this it is possible to tune the antenna circuit and at the same time tune the detector circuit. This circuit can be made even more selective by the addition of a variable condenser as shown in the dotted line. In direct line with these are the inductively coupled circuits. The simplest circuit of this type consists of a variocoupler, or loose coupler, crystal detector, phones, phone condenser, antenna and ground. There is no direct connection between circuit A and circuit B. Circuit A is the antenna tuning circuit and consists of the antenna, lead in, primary and ground. The secondary circuit is the secondary of the coupler, the detector, phones and condenser.

These circuits can be made more selective by the addition of condensers as shown in dotted lines in the drawings. In the coupled circuit the action is as follows: The antenna intercepts the transmitted wave and by means of the lead-in carries it to the primary of the circuit. This primary is tuned to the desired wave length and the current flowing in the first circuit induces a like current in the second circuit. This current being alternating (flowing first one way and then reversing) would not be heard in the phones, as the phones do not respond to the rapid alternations. The detector which is a uni-lateral conductor (allowing current to flow in one direction only) rectifies it and the current flows through the phones as a direct current, making the signals audible. Other circuits will be shown and explained in future issues of RADIO WORLD.

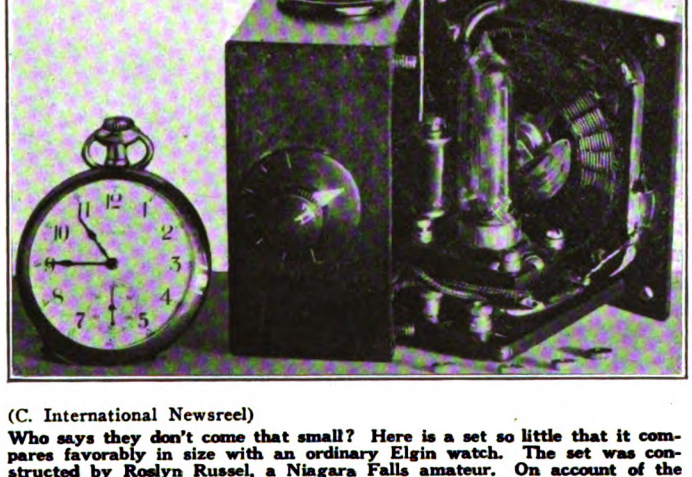
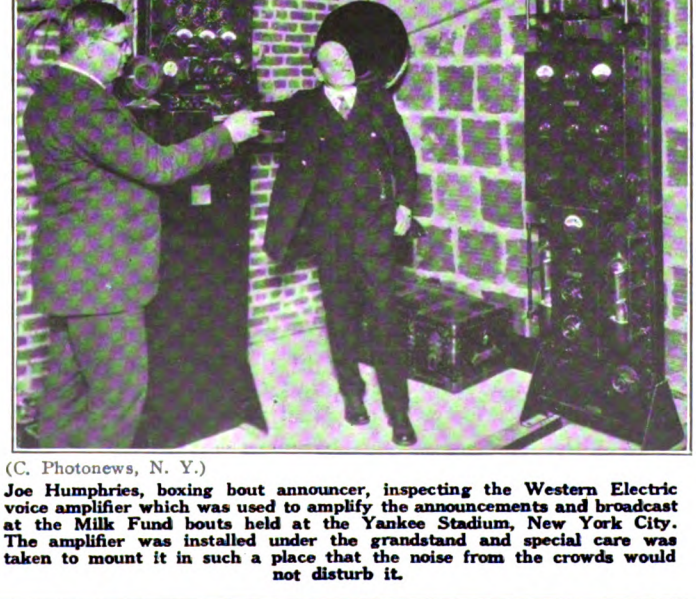
If you intend to travel, particularly between Cincinnati and Louisville, you may be assured that your trip will not be monotonous, no matter how travel hardened a traveling salesman you are. They have installed in the day coach, for the convenience of the passengers, a special receiver using radio-frequency, detector and power amplification, in conjunction with the Western Electric loud speaker, making it possible to hear broadcast programs above the noise of the train.



(C. International Newsreel)

Who says they don't come that small? Here is a set so little that it compares favorably in size with an ordinary Elgin watch. The set was constructed by Roslyn Russel, a Niagara Falls amateur. On account of the small space necessary a home-made spider web inductance was used. The tickler, being stationary, was wound inside of it and a special variable condenser was used. It has a range of 200 to 600 meters, and has copied stations over a radius of more than 900 miles.



(C. Photonews, N. Y.)

Joe Humphries, boxing bout announcer, inspecting the Western Electric voice amplifier which was used to amplify the announcements and broadcast at the Milk Fund bouts held at the Yankee Stadium, New York City. The amplifier was installed under the grandstand and special care was taken to mount it in such a place that the noise from the crowds would not disturb it.

Your Wave Lengths A

(C. Photonews, N. Y.)

Radio frequency meter used in the office of the Chief Radio Inspector, Second District, for measuring the impressed frequency of the transmitter of a distant station.

FEW people realize the constant activity on the part of the radio division of the United States Department of Commerce to keep an accurate check on the wave lengths of the various stations in the several districts. Every day in the year and every hour of the day there is some one in an official capacity checking up on the wave lengths of the various stations transmitting.

This is especially important since the allocation of the new wave lengths for the broadcasting stations. Down at the Custom House in New York City sits a man with a pair of receivers on his head and a high power receiver in front of him. In conjunction with this receiver there is an up-to-date heterodyne wave meter. This meter is of the most

Latest Offical List of Broadcasting Stations in the United States

FOLLOWING is the first installment of an official list of commercial broadcasting stations in the United States as issued by the Department of Commerce. The list will be continued in next week's RADIO WORLD.

As new allocations of wave lengths to stations now operating on 360 meters are made by the Department of Commerce, the changes will be published by RADIO WORLD.

Readers who save these installments will have a complete list of broadcasters with their station calls, location, frequency, wave lengths and power.

New DX Night Owl Records That Count

Two Lists to Make You Work

From D. Smith, 601 Russell Ave., Geneseo, Ill.

I HAVE been reading your paper a long time and am very much interested in the DX Nite Owl page. Here is my record on a crystal set using conventional hook-up: WOC, KYW, WDAF, WHB, WGY, KDKA, WJZ, WWJ, WCX, WLAG, WAAP, WAAF, KSD, WBAP, WFAA, WGM, WSB, WMC, WHAS, WLW, WOR, WCAE, WOS, WDAP, WJAN, 25 stations.

With Giblin-Remler coils and one tube hook-up I received the following list of stations: WSB, WDAP, WFAA, WLAG, WOC, KYW, WOS, KDKA, KSD, WLK, WHB, WIAK, WOAI, WDAJ, WIAS, WKY, WGM, WDAF, KHJ, WFAT, WAAE, WHAS, WBAP, WJZ, WWJ, WPA, WAAL, WBL, WJAP, WJAN, WIAO, WGY, WCX, WKN, WMAB, WBZ, WCAE, WOH, KFBS, WAAC, KFAF, WMAH, WGAY, KOP, WCM, WAAH, WFAP, WMAT, WBAQ, WOR, WEAF, WEAL, WMH, WHAZ, WAAN, WPAD, WNAD, KLZ, WLAL, WHAM, WNAJ, 9XAC, WMC, WRAM, WIAR, WCAS, WNAV, WAAP, WCAZ, IXAE, WOQ, WOAN, WBT, WHAA, WHA, WCK, WMAK, WGF, WNAB, WJAM, WFAJ, WSY, WWI, WHAB, WEAO, WKAA, WDAA, WGAS, WCAF, 9BDY, WPAC, KFBL, WIAA, WJAX, WAAW, WIAL, WHAH, WTAT, WTAU, WGR, WBAV, WWAD, WWB, WOAX, WBAS, WWD, WJAB, WHK, WIP, WDAO, WGV, KYY, KFBU, KXD, KFI, KWH, KDYS, KDZH, KGW, PWX, CJCG, CFCA, CKCK, CFCN, a total of 125.

The One Tubes Have It

From J. Shaw, 207 Jefferson Ave., Charlotte, N. C.

I HAVE been an interested reader of the RADIO WORLD for some time and thought I would send you my DX records from the "Queen City of the South." I am using a hook-up with two variometers, one 23-plate variable condenser, one detector bulb. I have heard the following stations: KDKA, WWJ, WKAS, WGM, WOH, WOE, WIZ, WSB, KSD, WHK, KDPM, WEAF, WOC, WGY, WJZ, WOR, WJAX, WDAS, WLW, WHB, WEY, WXY, WJAK, WHAK, WKAA, WMAQ, WFAA, WQAA, WLAC, WLK, WBAC, WBZ, WHAZ, WBAP, WDAP, WHAB, WDAF, WHAS, WHAF, WCX, WAAP, WIK, WEAT, WRT, WEAE, PWX, WKAN, WEAI, WJB, WEAO, WKAG, WSY, WEAS, WIP, WMC, WLC, VBG, KYW, WMC, WAAX, WAAK, KLZ, KFBV, WOO, WOS, WHA, KYY, WFS, WNAP, WOAI.

Some More CR9 Records

From Herbert Jones, 170 Beach 81st St., Rockaway Beach, N. Y.

YOUR publication of the letter of M. Davidson, Jr., Laurence, L. I., prompts me writing this to thank you for putting me in touch with another Grebe C. R. 9 owner, and if you will I wish you would publish my list of DX to date. I purchased my set March 7 and received all my stations up to the first of April. The past week the static has prevented any DX work for me. I have an aerial only 22 ft. high. I would also like to hear from other Grebe owners.

Station "Frank H. Jones," Lunicu, Cuba; WFAA, WBAP, WOAW, WHB, WDAF, WLAG, WOS, WMC, WOC, KSD, WDAL, WSB, WGM, WDAJ, KYW, WMAQ, WDAP, 9XU, 9KP, WWAY, WHAS, WLW, WPAL, WWJ, WCX, WCAE, KDKA, WBAZ, WHAM, NAA, 8AWP, WNAC, WLAK, WGI, WGY, WBL, WHAZ, 2XAP, WIP, WOO, WFI, WDAR, WRW, and 12 "locals." Total, 56.

THE Editor of RADIO WORLD will be pleased to receive sketches of hook-ups drawn carefully in black ink or heavy pencil from the "DX Nite Owls" who send in records with a view to publishing them.

Send hook-ups of your sets, provided they contain something unusual. Send, also, the names of the various makes of apparatus you are using.

Make your letters brief and informative. Write on one side of the paper only.

The letters and hook-ups will be published in the earliest possible numbers of RADIO WORLD.

* * *

Stations to the Right of Them Volleyed and Thundered

From Jack Price, 305 Tattnall St., Savannah, Ga.

I HAVE been a constant reader of your valuable magazine for nine months and must say it is "up to the minute" on all the new dope. I have gained much enjoyment as well as useful experience in testing various circuits taken from your pages. Have logged 78 broadcasting stations in 28 States, one in Cuba and Porto Rico and north to CFCA, Toronto, Canada, and west to KHJ, Los Angeles, which I deem good results on one stage of audio with only "thirty-six foot" antenna. Have also heard KDKA, WEAF, WWJ, WDAP and WBAP, Fort Worth, Texas, on crystal alone. Wish some O. M. would send me hook-up for straight key, C. W. using sufficient power to work eight hundred miles. Would be glad to hear from fellow DXers, and gladly QSL.

* * *

Not So Worse—I'll Say

From E. L. Kennedy, Purcell, Okla.

I AM greatly interested in your DX Nite Owl section of the RADIO WORLD, so I thought I would submit my record made with a honeycomb coil tuner and two stages of audio-frequency amplification. I have heard about one hundred stations, but am only sending those over a distance of one thousand miles.

KHJ, KWH, KFI, KOG, KFCL, Los Angeles, 1,225 miles.

KPO, KUO, San Francisco, 1,450 miles.

KDYS, Great Falls, Mont., 1,175 miles.

PWX, Havana, Cuba, 1,350 miles.

WKAQ, San Juan, Porto Rico, 2,250 miles.

WGY, WRM, Schenectady, New York, 1,400 miles.

CFCA, Toronto, Can., 1,175 miles.

CHCF, Winnipeg, Can., 1,060 miles.

CKCK, Regina, Can., 1,160 miles.

WMAC, Cazenovia, N. Y., 1,350 miles.

A Rare Old Bird Is Right

From E. A. Guilbault, New Orleans, La.

I AM a constant reader of RADIO WORLD and have a stack of them with all the interesting news and sketches in them. I have been experimenting with wireless for a number of years and find that RADIO WORLD has the best reading matter as well as hook-ups of any radio magazine that is published. The DX Nite Owl is sure an interesting old bird. I am somewhat a Nite Bird myself, but since I've got my new set to working and joined the DX Nite Owls, I've been saving money by staying in more and getting good results out of my set. The circuit I am using is regenerative. My aerial is 4 wires 70 ft. long and 52 ft. above the ground; the lead-in is 40 ft. and I am using but one WD-11 tube. Here is my record from March 5 to March 10: WSB, Atlanta, Ga.; KFI, Los Angeles, Calif.; KYW, Chicago, Ill.; PWX, Havana, Cuba; WMC, Memphis, Tenn.; WBAP, Ft. Worth, Tex.; WKY, Oklahoma City, Okla.; WOC, Davenport, Iowa; WWJ, Detroit, Mich.; WGM, Atlanta, Ga.; KSD, St. Louis, Mo.; WHB, Sweeny School, Kansas City, Mo.; WOAI, San Antonio, Tex.; WAAB, Wichita, Kans.; WDAC, Chicago, Ill.; WLAG, Minneapolis, Minn.; WOR, Newark, N. J.; WXY, Birmingham, Ala.; WOS, Jefferson City, Mo.; WDAJ, College Park, Ga.; WDAF, Kansas City, Mo.; WCAY, Milwaukee, Wis. I think for a one bulb set this is a fairly good record within five days. I am stationed at 4533 Iberville St., New Orleans, La.

* * *

Crystals Aren't So Worse for DX After All

From C. Dunlap, Kinmundy, Ill.

I AM a reader of your weekly and think it is the most up to date radio journal I have seen.

I am sending you a list of stations I have heard with a set consisting of a home-made two-slide tuner galena detector and a pair of 2000 ohm Manhattan receivers:

Call letters	Location	Distance
KSD	St. Louis, Mo.	60
WMC	Memphis, Tenn.	275
WHAZ	Troy, N. Y.	850
WSB	Atlanta, Ga.	425
WPA	Fort Worth, Tex.	650
WRR	Dallas, Tex.	625
WLW	Cincinnati, Ohio	225
WWJ	Detroit, Mich.	400
WOS	Jefferson City, Mo.	200
		3,780

* * *

Here's Your Chance—Owls

From Walter R. Scott, 285 Montague Place, So. Orange, N. J.

I AM sending a list of the most important DX stations I have received, hoping it will interest the "DX Nite Owls."

PWX, WBAP, WHB, WOC, WDAF, CFCA, KYW, KDKA, NAA, WBT, WBZ, WFI, WOO, WIP, WDAR, WGR, WGI, WHK, WLW, WMC, WMB, WSB, WGM, WWJ, WBAX, WBAZ, WCAE, WDAP, WEAS, WHAM, WHAS, WJAX, WMAF, WNAC, WNAL, WHAZ, WGY, WMAK, WLAK, WCX.

My set is a WD-11 tube, variocoupler, variometer and variable condenser. I will send my hook-up to any one who desires it provided a stamped envelop is sent for its return.

* * *

Records from Whaletown

From Benjamin Smith, 57 Prospect Street, New Bedford, Mass.

WHAT I received on a single U. V. 200 tube with a hook-up of the consolidated plan. I made my own variocoupler of No. 22 D. C. C. wire:

WCAS, WDAU, WDAY, WDY, WEAF, WEAN, WFI, WGAF, WGI, WGR, WGY, WHAF, WKY, WHAM, WHAT, WHAS, WHAZ, WIAP, WJAR, WJAX, WJAZ, WJC, WJD, WJZ, WLK, WLW, WMAC, WOC, WOO, WOZ, WQAQ, WWI, WWJ, WWT, WWZ, WOAP, NAF, PWX, KYW, WAAF, WLD, WJAP, CFCA.

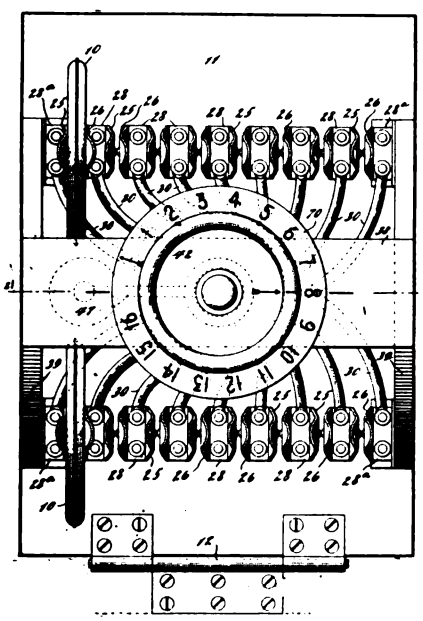
Latest Radio Patents

Spark-Gap Apparatus

No. 1,451,428: Patented April 10, 1923. Patentee: Lawrence J. Lesh, New York City.

This invention relates especially to spark gap apparatus for use in radio transmitting and receiving sets, the invention not being confined in all its features, however, to spark-gap apparatus. More particularly the invention relates to spark-gap apparatus of the multiple unit gap type, and the invention aims generally to



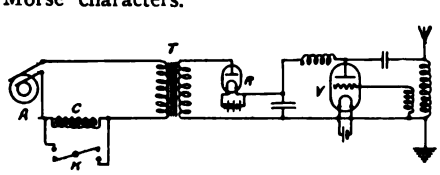
New method of arranging the units of a quenched gap for easy removal and adjustment.

provide improved apparatus of this type of a simple and compact construction and which shall provide for convenient and ready removal and replacement of the spark-gap units and for convenient adjustment of the circuit for connecting any desired number of the units and any desired group of the units in the circuit, and to provide an improved spark-gap unit. The invention consists in the features of construction, arrangement and combinations of parts herein disclosed and specifically pointed out in the claims.

Wireless Transmitter

No. 1,454,586: Patented May 8, 1923. Patentee: W. T. Ditcham, Twickenham, England.

The object of this invention is to provide an improved valve transmitter in which the transmission of the interfering noises known as key clicks may be obviated and the valve or valves may be relieved of the full load during the spacing periods of the Morse characters.



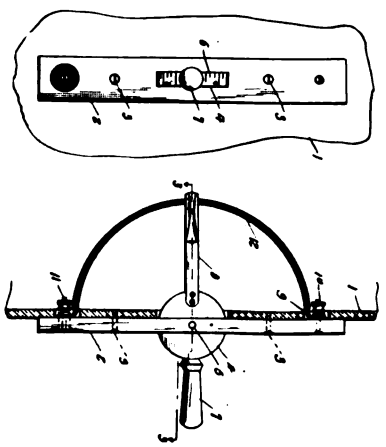
An improved valve transmitter.

According to this invention I connect in the primary power circuit of a valve transmitter a choke coil if the primary current is alternating, or a resistance if the primary current is direct, and I provide a key or switch by means of which this choke coil or resistance may be shortcircuited for the purpose of signaling. The choke or resistance should be of such a value that when it is not shortcircuited the valve will continue to oscillate but will only generate a small current compared to its normal working current. Thus signals can be transmitted by varying the strength of the oscillations without stopping their production or sensibly varying their frequency.

Radio Variable Rheostat

No. 1,452,399: Patented April 17, 1923. Patentee: Herman W. Tompkins, Greensburg, Pa.

The present invention has relation to radio apparatus and more particularly to a variable rheostat which is simple in its



Variable rheostat of new and novel construction.

structure and arrangement of parts, whereby it may be readily assembled and economically constructed, and which is accessible for any required purpose.

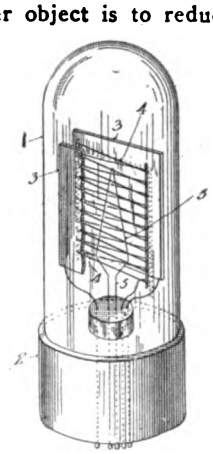
Electron-Emitting Cathode

No. 1,453,287: Patented May 1, 1923. Patentee: James L. Bradford, New York City.

This invention relates to the manufacture of the heated element, such as the filament, or electron-emitting cathode member of an audion or vacuum tube, and particularly to the element referred to, as an article, as well as to the method of making the same.

The object of the invention is to provide a filament or electron-emitting cathode of greatly increased durability and constancy of activity, for use in audions or vacuum tubes.

A further object is to reduce the cost



Bradford's improved electron-emitting cathode.

of manufacture of such devices while securing greater length of life thereof, and increased efficiency.

A further object is to provide an element of the nature and for the use referred to which requires less current in the use thereof, thereby reducing the cost of operation of audions or vacuum tubes in connection with which the element is employed.

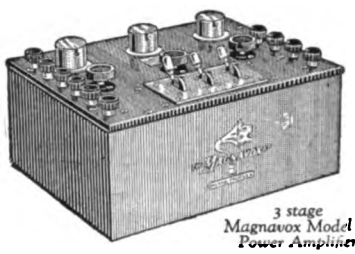
Radio Products



3 stage Magnavox Model C Power Amplifier

The Power Amplifier for your Magnavox Reproducer

The Magnavox Power Amplifier Model C, as illustrated, is a true *Power* Amplifier, and free from elements of distortion.

Switching from stage to stage is made easy by master switches. Any standard amplifying tube can be used.

Without Magnavox equipment, no Radio receiving set is complete.

Magnavox R3 Reproducer and 2 stage Power Amplifier . . . **$90.00**

R2 Magnavox Reproducer with 18-inch curvex horn: the utmost in amplifying power; requires only .6 of an ampere for the field **$60.00**

R3 Magnavox Reproducer with 14-inch curvex horn: ideal for homes, offices, etc. . . . **$35.00**

Model C Magnavox Power Amplifier insures getting the largest possible power input for your Magnavox Reproducer.

AC-2-C, 2-stage, $55.00
AC-3-C, 3-stage, $75.00

Magnavox Radio products can be had of good dealers everywhere. Write for copy of our new booklet.

Harold Schegel, 524 Second Street, Ann Arbor, Mich. (Builds radio sets.)
Stanley Delmar, 231 Allegheny Avenue, Fairmont, W. Va.
F. C. Hendershot, Spencer, Indiana.
Francis J. B. Leonard, 750 North State Street, Chicago, Ill.
E. S. Akin, 1520 South State Street, Syracuse, N. Y. (Wants catalogues of high class radio sets.)
Chas. R. C. Ham, care Wilson & Co., P. O. Box 615, Hongkong, China.
Economy Radio Supply Co., 1506 Lexington Avenue, New York City.
Joseph Schwartz, 3409 Beniteau Avenue, Detroit. Mich.
Lee Grubb, R. D. No. 1, Millerstown, Perry County, Pa.
I. N. Mitchell, 680 Fifth Avenue, New York City.
The Duluth News Tribune, Radio Editor, Duluth, Minn.
Lester O. Burton Maple Shade, N. J. (Distributor. Has demand for portable sets.)
William J. Vandercar, 63 Howard Street, Cohoes, N. Y. (Will soon stock parts and supplies.)

The first of these names were printed in Radio World dated April 21, and have continued in each issue since. Any copy 15c. Any 7 copies for $1.00. Radio World, 1493 Broadway, N. Y.

"Elements of Radio Communication"

"Elements of Radio Communication." A book for the engineer, amateur, student and layman, by Ellery W. Stone, 445 pp. 145 diagrams, 39 plates. D. Van Nostrand Company, New York.. Price, $2.50 net.

This is a second edition of Lieut. Stone's book revised and enlarged. Much new material and recent data on radio-frequency generators, air-craft radio, vacuum tubes and radio-telephone broadcasting are included in this edition. The book seems to be well adapted for classroom work as well as self instruction for radio amateurs and, in fact, any one interested in the art.

New York Radio Show Planned for September

PLANS are being formulated by the American Radio Exposition Company to hold another radio show in New York City. The last week in September has been mentioned as the opening date, but a definite announcement is expected in the near future. It is probable that the show will be held in either the Sixty-ninth Regiment Armory or the Seventy-first Regiment Armory. All inquiries should be addressed to J. C. Johnson, American Radio Exposition Company, 120 Broadway, New York City.

Radio Department Buyer and Manager Wanted

EDITOR RADIO WORLD: We have an opening in one of our large Radio Departments in the East for a buyer and manager. We want primarily a merchant and one who can promote sales. If you have some one in mind that you think is especially good and who has been running a successful Radio Department, we would like very much to get in touch with him.

Yours very truly,
RETAIL RESEARCH ASSOCIATION.
225 Fifth Ave., New York City.

Coming Events

ANNUAL HOME AND CITY BEAUTIFUL EXPOSITION, featuring radio exhibits, Atlantic City, N. J., June 16 to September 8, 1923.

PACFIC COAST ELECTRICAL ASSOCIATION, San Francisco, Calif., June 19-22, 1923; S. H. Taylor, secretary, 527 Rialto Building, San Francisco, Calif.

CANADIAN ELECTRICAL ASSOCIATION, Montreal, Canada, June 21-23, 1923; Louis Kon, secretary, 65 McGill College Avenue, Montreal, Canada.

Farmers Need Radio Sets

MR. E. S. AKIN, president of the New York Draft Horse Club, of Syracuse, N. Y., is a radio enthusiast and a valued reader of RADIO WORLD. He expresses the opinion that, if properly demonstrated, radio outfits could be sold more generally to farmers in central New York.

A New Federal Transformer

The Research Division of the Federal Telephone & Telegraph Company, Buffalo, N. Y., has during the last year made several interesting discoveries in its work on the theory of and means for the faithful reproduction of music. The results of successive trials have proven beyond doubt that what the ear of the observer needs for complete satisfaction in music is the presence of the lower tones of the orchestra. Its lack leaves a distinct feeling of dissatisfaction and insufficiency in the music while its presence gives a completeness and satisfaction that constitutes the difference between good music and what the radio listener has been forced in the past to accept.

While the problem of the loss of the lower tones is as serious in the transmitting equipment as in the receiving equipment, the fact that one transmitter serves many thousands of listeners has justified the great investment necessary for the construction of special faithfully reproducing microphone and voice amplifying equipment. But the problem of designing equally good equipment for the radio listener has been attended by the same difficulties and with the added limitation that the selling price of such equipment must be well within the reach of the radio listener.

The methods for the elimination of these many difficulties lie in the careful design of the amplifying transformer. The matter is one that requires the greatest possible care in choice of proportions, nature of the materials involved, and their more careful fabrication and assembly.

The No. 65 Federal transformer has been designed to eliminate the objections that have so limited reproduction in the past. Its design and construction is such that the notes of the bass viol, the kettle drum, the piano bass are carried through the system with a completeness and faithfulness that is amazing.

It is of such construction that each note that enters it is passed on to the vacuum tube with exactly the same fidelity and without a suggestion of any added tones, whether dissonant or not. And, when used with UV-201, WD-12, UV-199, or any of the other commonly available tubes the degree by which this exceptionally satisfactory amplification exceeds that which has yet been available with any A. F. transformer is said to be almost unbelieveable.

New Radio and Electric Firms

Electronic Corp. of America, Philadelphia, $600,000. (Corporation Guarantee & Trust Co.)

Economy Radio Supply Co., dealers in radio sets and parts; 1506 Lexington Ave., New York City. H. Hirschfield and others.

Fall Kill Radio & Electrical Corp., Poughkeepsie, N. Y., $50,000; J. A. Purcell, J. B. Grubb, W. A. Cronk. (Attorney, T. Purcell. Poughkeepsie.)

Nolte Mfg. Co., 61 Gautier Ave., Jersey City, N. J., to manufacture Reinartz coils.

Rhason Radio Corp., New York City, $50,000; R. J. and C. R. Heitman, H. A. Datter. (Attorneys, Halbert & Quist, 1293 Myrtle Ave., Brooklyn).

Windham Valley Electric Co. has increased its capital from $25,000 to $75,000.

Answers to Readers of Radio World

Will the three tube reflex circuit using the Grimes inverse duplex principle give as good results as a set employing three stages of radio-frequency, crystal detector and two stages of audio-frequency?

Can the R. C. A. Radio 1714 and Audio 714 be used in this circuit?

Which is the better tube for use in the circuit, the U. V. 199 or the 201A?

How can I make small neutrodyne condensers?—F. W. Logren, Box 649, Virginia, Minn.

You will get louder signals in the set employing three stages of radio, detector and two of audio. With the reflex you will obtain signals equal to two stages radio, detector and two of audio. The advantage of this circuit is the saving in tubes and in current. You can employ the transformers you mention. Either of these tubes will function properly, but you will obtain slightly more volume by using the 201. See article by J. E. Anderson in this issue on neutrodyne condensers.

* * *

I have been experimenting with the Reinartz tuner hook-up and have had good results but with one exception. I cannot get many amateur stations. I have been told that my antenna is too long for this. It is 310 feet long, fastened to a tree at one end and the gable of the house at the other. Should I cut it down? This is about the only place that I can conveniently place it.—Arthur Greben, Liberty, New York.

The antenna you mention is entirely too long for reception of amateur signals. One hundred or 150 feet at the most is plenty for all waves that you wish to receive. You will get better results and sharper tuning with a small antenna. You can run your wire out for 100 feet, fasten your insulator, and support the rest of it on rope. That will serve the purpose.

* * *

I have a crystal set comprising a loose coupler, variable condenser, fixed condenser, phones and Turney Crystalor detector. Can I use any of this apparatus in the construction of a single tube set? What will be my range using one of the WD-11 tubes and the apparatus mentioned? Would putting a one stage amplifier on my present set increase the distance over which I can receive? How far can the average crystal set be relied upon to receive with an outside antenna and the best apparatus obtainable? —Alfred Wagannor, Utica, Utica, N. Y.

You can use the loose coupler, variable condenser, fixed condenser and phones in the set you intend making for the WD-11. It is impossible to state the range of any receiver. The only method you can pursue is to construct the receiver and try it out for yourself. It would not increase your range to add an amplifier, as an amplifier will not boost anything that is not audible in the detector circuit alone. It would make louder the signals that you now receive. The average crystal set is good for 50 to 75 miles on telephone and 100 to 150 miles on spark work at the best average times. Freak reception has been covered over longer distances, but the consistent range of crystals is not large.

* * *

Enclosed please find a diagram of a circuit described in Radio World *for Jan. 27, 1923. Would it be possible to put radio-frequency on this circuit? If it is possible, what apparatus is necessary?—Gerald R. Duncan, Fayette, Iowa.*

It is not possible to put radio-frequency amplification on this circuit without destroying the basic principle of its operation.

* * *

In Radio World *for Feb. 24 you describe the Flewelling circuit. Will a* WD-11 *be suitable for this circuit? What voltage is necessary on the plate?—W. C. S. Holden, Valdosta, Ga.*

You can use this tube in the Flewelling circuit. The plate voltage should be 45-60 for volume, although 22½ will work, but with poor success.

* * *

Where can I obtain the neutrodons and neutroformers necessary for the Hazletine neutrodyne circuit? What tubes should be used with this circuit, and what is the type of radio transformer used?—John C. Kerr, 160 Broad St., Providence, R. I.

You can obtain the apparatus you desire from Freed-Eiseman Corporation, 255 Fourth Ave., New York City. For best results the U. V. 201A should be used with this circuit. No radio frequency transformers are used with this circuit, the neutrodons taking their place.

* * *

What is the best type of transformer to use in connection with adding two stages of audio-frequency to the set described by Orthcrus Gordon in Radio World *for Jan. 20. I have R. C. U. V. 712, but have been told that they will not work in this circuit. Would a phone condenser bridged across the phone terminals improve this circuit to any extent? What capacity should it be?—A. M. Wiggins, Box 463, Jacksonville, Fla.*

The transformers you mention are perfectly o. k. for use with this circuit and whoever has been telling you differently is wrong. You can use such a condenser. It would not improve your reception to any great extent, but would make the signals clearer to some extent. It should be .001.

* * *

How many turns of No. 22 D.C.C. wire will be necessary to wind on a tube 4 inches in diameter and 4 inches high to enable me to receive broadcasters? There is to be ⅞-inch left for rotor mounting. What ratio transformer is desirable for the first stage of audio-frequency using WD-11 tubes? What for the second stage?—Alfred R. Golze, 1715 Corcoran St., N.W., Washington, D. C.

Thirty-five turns on each side of the division will be sufficient for all your needs. This will make the winding about 1½ inches on each side of the ball and will allow sufficient for each end. A transformer of 9-1 is preferable for the first stage and one of 4-1 for the second.

* * *

Will I be able to work the Cockaday four circuit tuner set published in Radio World *for May 12 on WD-11 tubes? Must the sizes of the windings be strictly adhered to?—F. M. McCormack, 158 Webster Ave., Providence, R. I.*

The circuit mentioned will work on WD-11 tubes but you will not get the volume that you would get out of the 201 or 201A tubes. The small change in the size of tubes you mention should not make any great difference.

* * *

Will the Cockaday circuit get all the new stations operating on the new wave lengths? Does the information on the construction of the coils have to be strictly adhered to? What should the ratio of the transformers specified be?—Jos. Spolarich, 210 Ruby Street, Joliet, Ill.

The coils specified will allow you to get all the new stations with the aid of an antenna about 100 ft. in length. It is best to follow the instructions exactly. The first transformer specified (Amertran) is 9-1 and the second 3-1. This, with the proper B battery voltage, will allow operation on a loud speaker.

* * *

Is it possible to obtain peep hole milliameters with a range of .0 to 1? Will such an instrument placed in the plate circuit of a regenerative set have any effect on the working of same? Will it allow the condition of the B battery to be told?—E. L. Thomson, Maranville, Tex.

Milliameters are not made for peep hole mounting. The small size is 2½ inches in diameter and can be obtained at or through any electrical store. Such an instrument placed in the plate circuit will have no effect on the working of the set. It will allow you to tell the condition of your battery to a certain degree, but not as authentically as a voltmeter, as the amount of amperage in such a battery is extremely small at best.

* * *

Enclosed please find the circuit described by Mr. Stoup in Radio World *for May 12. How should variable condenser C1 be connected in circuit to prevent capacity effects? Do arrows on rheostats and potentiometers mean movable arms? Would a dry cell be strong enough to operate the tube? Should plus of B battery go to plus of socket? In sketch, the plus of A battery also goes there. What is the capacity of C3 and C4? Does ground of secondary circuit that goes from the plus of the A circuit have to be a separate circuit from the primary ground? —J. H. Curtis, 1314 W. Front St., Plainfield, N. J.*

The rotor of the condenser should connect to the side of the secondary going to the grounded side of the filament circuit. The arrows signify the movable contact arms. A dry cell will operate this circuit if a WD-11 is used. The plus of the B battery always goe to the plate (marked P on socket). You evidently have your connections mixed. There are two filament connections on a tube socket, marked FF or F+ and F— or — and +. The plate and grid are marked P and G. Do not get these mixed up simply because the plus of the B battery goes to the plate. Do not make the mistake of connecting the B battery in such a manner that it will cross the filament leads, or you will burn out your tube. The best method to pursue in preventing this is to place an ordinary electric light bulb of either 60 or 75 watts in the B battery leads to act as a ballast lamp. If by chance there is a direct circuit, the bulb will take care of excess current and will prevent you from burning out your filament.

* * *

Where can I obtain a complete hook-up for the WD-11 receiver published in Radio World *for March 3, on page 9, by C. White?*

What voltage is the best for the B battery circuit in this hookup?—Henry W. Schwab, 201 Buell Street, Muscatine, Ia.

The entire hook-up was shown on the page you mention. We do not supply blue prints of circuits. 22½ volts on the plate will be enough for all WD-11 tubes when used as detectors.

Baseball Writers Protest Broadcasting Baseball Plays

THE Baseball Writers' Association of America is opposed to the radio broadcasting of baseball results from major league parks throughout the country, it became known last week when the association wired Commissioner Landis and Presidents Heydler and Johnson, of the National and American Leagues, protesting against alleged granting of permission to a radio corporation to provide facilities for this purpose.

The telegram, signed by Frederick G. Lieb, of New York, president of the association, and Joseph M. McCready, of Philadelphia, secretary, is as follows:

"Understand permission has been granted to a wireless corporation to broadcast results of games at Polo Grounds and other parks throughout the country, giving detailed results play by play. If this is permitted, it will kill circulation of afternoon papers and in the end will result in curtailment of baseball publicity.

"The Baseball Writers' Association is strongly opposed to allowing any wireless connection with the baseball parks which would allow broadcasting stations to give details while a game is in progress."

Farmers Benefit by WOC's Broadcasting Schedules

That the daily broadcasting schedules given by Station WOC, owned and operated by the Palmer School of Chiropractic, at Davenport, Iowa, are of special benefit to the farmers is becoming more evident continually.

Farmers who have not already installed receiving sets visit their neighbors who have this wonderful new means of communication with the daily activities and see what benefits are to be derived.

The inspiration behind the Palmer School of Chiropractic has always been that of public service, and this institution has ample opportunity to carry out this idea of service through its radio programs. Located as it is in the middle west, and the center of a large farming population, it has been mindful of the fact that a large percentage of its potential audience is made up of farming folk and has endeavored to make its schedules of interest to them in particular.

Blue Law Silences Radio Loud Speakers

MANY years ago, the Elizabeth, N. J., Board of Works passed an ordinance prohibiting peddlers and others from making noises on the streets. This ordinance was invoked last week to stop the use of large phonograph horns in front of stores of radio dealers. Chief of Police Mulcahy says the use of these horns violates the ordinance as a "nuisance." The dealers argue that the ordinance was passed before radio was thought of, but the Chief was obdurate and said the use of horns to distribute radio messages will have to end. The dealers indicated they will fight the police ruling.

Performing Artists Now Want Broadcasting Royalties

IT is now rumored that the performing artists will demand revenues from the broadcasting stations for giving other types of entertainment than music. Payment to singers and dance orchestras is said to be among the possibilities.

RADIO BROADCASTING MAP

FOR the benefit of those interested in Radio and those who are becoming interested, Rand McNally & Company have prepared a publication containing a wealth of information of greatest value. It shows in the most comprehensive way, the location of the broadcasting stations, gives their classification, the call letters, wave lengths, ownership, etc., of each.

The Rand McNally Radio Map of United States is 30x40 inches in size. The locations of broadcasting stations are shown by distinctive symbols. The call letters of each station are given, also the wave lengths of each. The Radio Districts with numbers are shown in red and the Radio Relay Divisions are in blue. Time zones are included. Alphabetical lists of stations and alphabetical lists of call letters are in the margins. Convenient pocket form with cover.

THE COLUMBIA PRINT

1493 BROADWAY NEW YORK CITY

Features of the Program at WGY Next Week

RADIO listeners tuned to WGY, the Schenectady broadcasting station of the General Electric Company, Sunday evening, June 10, will have an opportunity to take part in the opening service of the 127th Commencement of Union College. On that evening Dr. Charles Alexander Richmond, president of the college, will deliver the baccalaureate at the First Presbyterian Church. Several Schenectady clergymen will take part in the service.

A feature of the week of June 10 at WGY will be a program by the Monday Musical Club of Albany, N. Y., under the direction of Mrs. Ralph G. Winslow, Monday, June 11.

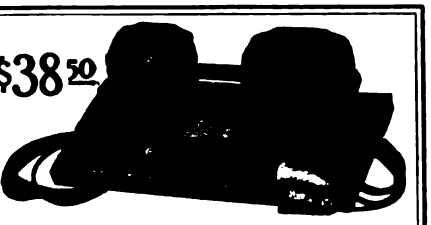
Frederick J. Clinnick, cornetist, will be featured on the program for Tuesday, June 12. A Flag Day address will be delivered by the Rev. William E. Compton, Thursday night, June 14.

"Clarence," a comedy by Booth Tarkington, will be presented by the WGY Players Friday night, June 15, with Edward H. Smith as Clarence. At the late concert, Friday night, an all Irish program will be presented.

Broadcast Designations—Not Official!

Now that what is known in newspaper offices as the "silly season" is approaching, it is but natural that radio should come in for its share of nonsense. The first attempt to reach RADIO WORLD is the following list of well known broadcasting stations:

WOR—"Waves of Romance."
WJZ—"With Jazzy Zip."
WJY—"With Just Youthfulness.
WHN—"We Hinder Not."
WEAF—"We Exploit All Favorites."
WHAZ—"We Handle All Zones."
WGY—"We Grow Younger."
WOC—"We Oversee Crops."
WHAM—"We Handle All Matters."
WSB—"We Slay Bollweevils."
WDAP—"We Do Atlantic-Pacific."
PWX—"Please Wire Xchange."
WAAM—"We Are Active Merchants."



$38.50

RECHARGE YOUR OWN BATTERIES

WHY pay good money out constantly for recharging batteries when the Ohio Motor Generator will do it quickly at a slight expense. This inexpensive home charging outfit keeps your Radio in service all the time and pays for itself—by charging your neighbors' batteries. It is noiseless, gives no trouble, and will even recharge totally exhausted batteries quickly.

The set is made up of the celebrated Ohio A C motor and D C generator wound for 6-10 volts. The motor and generator have ball bearings and are of the highest grade construction. It has none of the troubles common to cheap charging sets and will last a lifetime. It will charge quickly any three cell automobile or Radio "A" battery. Furnished complete on a substantial base with ammeter and field rheostat to adjust the charging rate from one to twenty amperes. The motor is for 60 cycle, 110 volt service and is complete with ten foot cord and attachment plug ready for instant connection and operation. Full instructions provided.

Motor and generator can be specially wound to charge six cell batteries or other unusual conditions.

Price $38.50 f. o. b. Cleveland. Ship by Express C. O. D., weight sixty pounds. Send your order today and stop paying good money for recharging. Your money back quick if not satisfactory.

NOTE:—If your service is other than 60 cycle, 110 volt, ask for special price.

Also 2 Step Unit 14.50
Assembled Jacks, Sockets, Transformers, etc., ready in one piece for mounting. Most compact unit available.

SUNBEAM ELECTRIC CO.
71 THIRD AVENUE NEW YORK

Directive Radio Transmission on a Wave Length of 10 Meters

UNDER this title the Bureau of Standards has issued Scientific Paper No. 469 by Francis W. Dunmore, Associate Physicist, and Francis H. Engel, Assistant Physicist, of the Bureau. An abstract of the paper follows:

Interference between different radio transmitting stations can be reduced by the use of markedly directional antennae for transmitting and receiving and by the use of short wave lengths not at present employed. For broadcasting, such as the transmission of market reports or music, directional antennae are not suitable for transmitting, but can be used for reception. For point-to-point communication—that is, from one transmitting station to one receiving station—directional antennae can advantageously be employed for both transmission and reception. Radio communication has so far been carried on, with few exceptions, on wave lengths of not less than 200 m. The use of much shorter waves, such as 10 meters, with the accompanying reduction of interference, has not been adopted to any extent. Experiments recently made by Marconi and others have shown them to be practicable.

This paper describes a series of experiments in radiotelegraph and radiotelephone transmission on a wave length of 10 m. using at the transmitting station a reflector consisting of short, vertical wires arranged as elements of a parabolic cylinder. The system described, therefore, employs two means of reducing interference. In the work described in this paper a 50-watt electron-tube generating set was employed. The capacity between the elements of the tube, together with the grid and plate coupling coils, formed the generating circuit. Waves were radiated from the generating set by two short, vertical, multiple-wire conductors, one placed above and one below the generating set. A coupling coil was connected between the two vertical conductors, and the generating set thus coupled to the system. The generating set with the vertical conductors was suspended in the focal axis of the parabolic cylinder. Each wire of the reflector was tuned separately to 10 m. by adjusting its length. With all adjustments of the reflector correctly made, good directional transmission was obtained. At least 75 per cent of the radiated power was confined to an angle of 40°.

Studies were made of the effect of removing the wires near the center of the reflector, of removing alternate wires in all parts of the reflector, of detuning the wires, and of varying the aperture of the reflector. For studying the radiation characteristics of the system, a single-turn loop-receiving antenna was used with a small condenser, thermo-couple, and micro-ammeter. Measurements of received current were made with this receiving apparatus while the transmitting reflector was rotated. Radiation characteristics for various adjustments of the reflector are shown by means of polar curves.

The paper gives the constructional details of the apparatus employed, so that any person interested can duplicate the apparatus used and the results obtained, and can continue in this line of investigation.

131 WEST 37TH STREET, NEW YORK CITY

Something Really New!

The Ideal Set for Travel, Home or Camp

The set that has taken New York by surprise. Its *loudness* is equal in volume to One Stage of Amplification on a good set. There is only *One Control.* Extreme simplicity is attained by the use of one dial. A *selectivity* which will tune in and out of local and distant stations when the traffic is heavy. In *distance* it has surpassed the best regenerative sets. A 200 to 1,250 meter range makes it possible to neatly handle the *new wave lengths.*

All this is enclosed in a trim cabinet *2" x 6" x 8".* Think of that for convenience! It only *weighs 2 lbs.* when *packed* ready to mail.

By organizing our production on a large basis we have been able to use the best materials and still sell this Wonder Set at only **$12.50**

Special discounts to dealers.

French Radicals Attack Broadcasting

The radical newspaper *L'Ere Nouvelle* published last week a violent attack on radio broadcasting on the ground that it is undemocratic. The New York *Sun* correspondent at Paris cabled his paper the following quotation from the attack:

"It is possibly the hardest blow ever struck at democracy. Wireless telephony contains nothing equitable. By the fashion in which it is organized it institutes a despotism. Speech becomes a monopoly in law and in fact. The people become a mute whose ears are filled with what the authorities decide to give them.

"Two kinds of things will be given this mute. First, unimportant facts and items of news. Then will come tendencious news designed to provoke simultaneously everywhere the passions of the crowd by official discourses and Government hints or indications useful to the economic and financial powers associated with the Government.

"Directly or under cover of limited liability companies the Government and reaction will be able to say to millions of listeners just what they want them to hear and there will be no contradiction."

Old WJZ's Senior Operator Becomes Chief at WBZ

WITH the closing down of old WJZ in Newark, N. J., came the passing of many familiar radio personalities. OHN is one of them. In real life he calls himself Harry E. Hiller. As the letters indicate, he was the senior operator attached to the Newark staff. And now, after the shutting down of the famous old station, he is going to WBZ, the Westinghouse Station in Springfield, Mass. He will become its chief operator, and will bring with him some of the fame which belongs to old WJZ.

The story of OHN is the story of WJZ. Hiller is a seasoned radio man, and an old hand at the game. He started his radio activities in 1912 presumably stringing a flimsy antenna on the paternal roof, as many youths of the period were wont to do. He secured a government license and after successfully passing the examination, was assigned a transmitting call 2IH.

It was then that he decided to pursue radio as a career and during 1918, he became an instructor at the Y. M. C. A. radio school in New York City. Later he joined the International Radio Telegraph and Telephone Company, who were making radio aeroplane material for the U. S. Government. After learning the essentials of radio manufacturing, Hiller decided to get some real operating experience.

He achieved a life long dream by shipping as a radio operator and liked it so well that he stuck to the sea till 1920.

It was in 1920 that he joined the Westinghouse Electric and Manufacturing Company in Newark, N. J., but the real radio work did not begin until he was attached to the radio staff in 1921, when preliminary experiments were begun between Newark and East Pittsburg.

OHN's first broadcasting experience occurred on the 4th of July, 1921. This was a memorable day also for boxing fans, as well as radio fans, as on that date the Dempsey-Carpentier fight was broadcast.

Bishop Says Radio Cuts Down Church Attendance

BISHOP WILSON R. STEARLY, of Newark, N. J., is quoted as saying:

"The widespread use in private houses of wireless apparatus lays a fresh responsibility upon the clergy and laity in regard to services of the church. It is debatible whether the broadcasting of sermons of popular preachers and of entire church services will act as a stimulant or a deterrent to church-going.

"Why go to your parish church when you can sit at ease in your parlor and hear the heavenly music of a capable choir and be charmed by the fervid eloquence of a magnetic preacher?

"There seems to have entered into our crowded and throbbing life another ally of those forces which make more difficult the assembling of the faithful for praise and prayer. The habit of church-going has a hard time in the face of Sunday excursions, movies sacred concerts, automobiling and broadcasting.

"Now it becomes necessary for the clergy to make the church more attractive than the world's entertainments, to discover to men the possibilities within it for strength and refreshment, and the gifts of grace in its bestowing, more precious than earthly things."

IMPORTANT NOTICE

While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

Physician Summoned by Radio

THE steamship "West Cahous," lying at anchor in Baltimore harbor, about nine miles from the city, needed medical help at about 3 a. m. recently and needed it quickly, reports the U. S. Public Health Service. A member of the crew had fallen into the hold and had hurt himself seriously. So the captain of the ship sent a wireless broadcast asking help.

The call was picked up, not in Baltimore, nine miles away, but at Cape May, N. J., about 100 miles due east of Baltimore. As Cape May was separated from the "West Cahous" by parts of New Jersey and Delaware and by the eastern shore of Maryland, not to mention Delaware and Chesapeake bays, no direct help from it was possible.

But the operator was on the job. Promptly he consulted the long distance list in the Baltimore telephone directory and called up the residence of the Public Health Service surgeon in charge of the Marine Hospital in Baltimore—100 miles to the west. The surgeon, roused from sleep to receive the message, asked him to radio certain emergency treatment to the "West Cahous" and to direct the captain to send a boat to a certain pier in Baltimore, where he would find a surgeon waiting to go out to the ship with him. And so, in the middle of the night, in less than an hour, a wireless-controlled sea-going ambulance carrying a Public Health Service officer, reached the side of the injured sailor and brought him

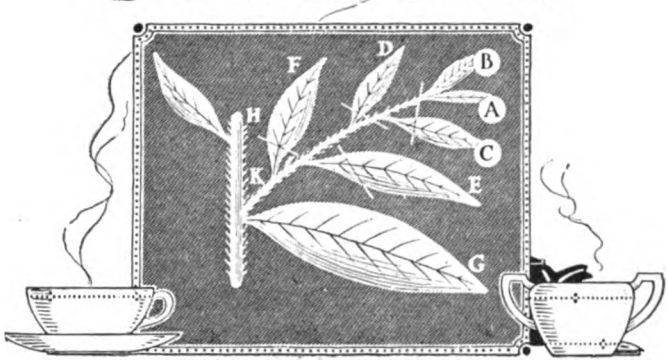
The A.B.C. of Good Tea



THIS diagram shows clearly one reason for the superior flavor, strength and aroma of RIDGWAYS TEA.

The plucking season commences in the early Spring and continues right into the Autumn. At the commencement of the season, the plant sends forth its first tiny shoots. In order to get the very choicest pickings, only those leaves marked "A," "B" and "C" are gathered for Ridgways. These tender, young tip-leaves give to Ridgways Tea that rare quality of flavor which distinguishes the famous Ridgway blends. The leaves marked "D," "E," "F" and "G" are coarser and less flavory and therefore *are never used by Ridgways.*

This carefully guarded Ridgway quality also assures more cups to the pound. When you buy Ridgways Tea you not only get the best tea, but actually more of it than is possible from inferior tea. As an example of rare good tea we suggest that you order Ridgways (GOLD LABEL), the *Genuine* Orange Pekoe.

Be Sure to Insist Upon

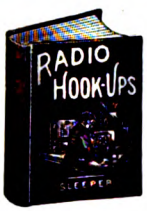
IF YOU ARE INTERESTED IN RADIO YOU NEED THESE BOOKS

Radio Books for the Expert and Amateur

Telling How to Operate a Radio Set—How to Build a Set—Principles of Vacuum Tubes and Other Radio Problems



Radio Hook-Ups

By M. B. SLEEPER

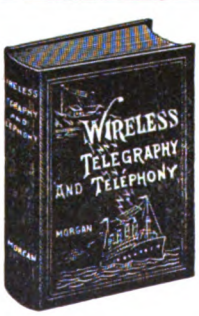
A book that gives you not only clear diagrams for all kinds of telephone and telegraph receiving and transmitting sets, but simple descriptions of each circuit shown and spaces for notes of results obtained.

PRICE 75c.

Construction of New Type Transatlantic Receiving Sets

By M. B. SLEEPER

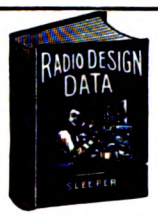
There is a peculiar fascination about receiving radio messages from the high-power stations of England, France, Germany, Russia and Italy, as well as those located in the Pacific Ocean and the Oriental countries. Several types of simple receiving sets for this purpose are described, with detectors and amplifiers to accompany them. Suggestions are also given for operating relays and reproducing the signals on a phonograph. Schedules of operating time for high-powered stations are given. In addition, there is some valuable data on home-made wavemeters for testing and experimenting .....PRICE 75c.



Wireless Telegraphy and Telephony Simply Explained

By ALFRED P. MORGAN

One of the most complete and comprehensive treatises on the subject ever published. A study of its pages will enable one to master all the details of the wireless transmission of messages. The author explains in simple language the theory and practice of wireless telegraphy and telephony. 154 pages, 156 engravings.....PRICE $1.50



Design Data for Radio Transmitters and Receivers

By M. B. SLEEPER

The only book that gives tables and data for designing, receiving and transmitting apparatus so that you need no knowledge of mathematics. It's the first book a beginner buys after he has learned the use of his phone receiver.....PRICE 75c.

Construction of Radiophone and Telegraph Receivers for Beginners

By M. B. SLEEPER

The man who wants to feel the real thrill of accomplishment, and who is not satisfied in the merely making use of what others have done for him, builds his own radio apparatus. Radio men can follow the data in "Radio Phone and Telegraph Receivers" with full confidence, because each piece of apparatus described was first made, tested and found efficient before the final design was accepted. Special receivers, both crystal and audion, are shown in detail. Regenerative circuits as well as audio and radio frequency amplifiers are described with clear photos, diagrams, and working drawings prepared especially for the novice and the man who wants to receive the radio telephone broadcast. A special feature is the phonograph type radio set and the loud speaker. Fully illustrated.....PRICE 75c.

The Radio Experimenter's Handbook

By M. B. SLEEPER

Throughout the preparation of this book, one purpose was kept in mind—Answer the Practical Questions of the "Novice," of the "Beginner," and the more advanced "Student." This book will help in the selection or construction of simple apparatus for the transmission and reception of radio telegraph and telephone signals. In the chapters on radio receivers the simplest crystal, the simple audion, and the regenerative types are described in quite some detail. The question of antennas, both for transmitting and receiving, are taken up. A good many helpful suggestions are given which will be of considerable aid to the experimenter. 16 chapters. Fully illustrated.

PRICE $1.00

The A B C of Vacuum Tubes Used in Radio Reception

By E. H. LEWIS

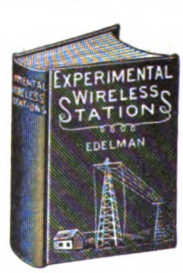
Assoc. I. R. E., and Radio Instructor

Written particularly for the person who "knows nothing about radio," but who would like to gain an understanding of the elementary principles of operation of vacuum tubes and various circuits in which they are used for the reception of radio-telegraph signals and radio-telephone music and speech. Illustrated.....PRICE $1.00

How to Make Commercial Type Radio Apparatus

By M. B. SLEEPER

This book describes in detail many commercial types of spark and vacuum tube telephone transmitting and telegraph and phone receiving equipment of all kinds. The experimenter will be able to get a world of ideas for the design and construction of his next piece of radio equipment from the very clear descriptions and the 98 clearly illustrated figures.....PRICE 75c.



Experimental Wireless Stations

By P. E. EDELMAN

Tells how to make apparatus to not only hear all telephoned and telegraphed radio messages, but also how to make simple equipment that works for transmission over reasonable long distances. Then there is a host of new information included. The first and only book to give you all the recent important radio improvements, some of which have never before been published. 392 pages, 167 illustrations.....PRICE $3.00

Any of These Books Sent Prepaid on Receipt of Price

A Portable Radio Set with "Roller Skate" Attachment

By D. L. Brown

The Brown Hum Dinger DX accompanying the "Roller Skate" on a pleasure jaunt.

THE following is a non-technical description of the Brown Hum Dinger DX Portable Radio Receiver with the Roller Skate attachment. Let me say this is not intended to interest those who can afford an expensive outfit as the cost of the parts should not exceed $20.00. It is best not to tell all we've heard with this set.

As will be noted from the diagram on page 12, the hook-up is entirely novel owing to the fact that the rheostat is in series with the plate circuit thereby eliminating the necessity for all potentiometers, variometers, taps, switches, etc. The two terminals at the upper northeast and northwest corners of our suit case set may be attached to anything handy, preferably a water pipe and the ordinary antenna of the outdoor species. These are interchangeable and we have heard a human voice when there was no connection whatever. The set works remarkably well on a loop as well as the indoor attic type of antenna. However, with the regulation 150 ft. antenna 30 ft. high and a cold water pipe for a ground, the phones may be hung on the wall and the clocks down stairs regulated by the time signals heard down the stairway—that is, if one has a stairway. WJZ and WEAF come in with sufficient volume to be clearly heard in an ordinary room with one of the head set phones attached directly to a phonograph horn.

The photograph of the front elevation of the Hum Dinger clearly shows that a set of Turney phones is attached to the terminals inside the front cover which just at this moment makes a convenient writing desk. A pencil and pad are kept handy for no one knows what may happen next. A roll of No. 18 bell wire 150 ft. long can be carried together with the phones closed

New York Electrical Interests Form Board of Trade

The electrical interests in New York City and vicinity have organized the Electrical Board of Trade of the City of New York with Arthur Williams, of the New York Edison Company as president and Charles L. Eidlitz as chairman of the board. Mr. Eidlitz recently was appointed arbiter of the electrical contractors' and dealers' interests in New York.

The Board of Trade will act as a clearing house for credits and other information desired by the trade. Membership will be held by representatives of the lighting companies, telephone and telegraph companies, manufacturers, jobbers, contractors, distributers, dealers and the electrical press within 25 miles of the City Hall. The purposes of the organization are: "To promote generally the interests of the electrical industry; to deal with problems concerning or affecting the industry; to represent the industry in public affairs or legislative matters affecting the industry; to be the central organization and headquarters for the entire electrical industry of the City of New York and territory; to promote the growth of the industry through the coordination of effort in the rendering of more extensive service to the public, based on the conviction that the most efficient service will elevate the industry to a plane that its usefulness deserves."

The Electrical Board of Trade shall not, however, it is stated, in any way deal with prices, "nor shall it foster combinations or agreements in restraint of trade."

The organization will be controlled by a Board of Governors consisting of three representatives elected from each branch of the industry, and will number 36 men, representing 3,000 firms, corporations and individuals.

The officers elected besides Mr. Williams and Mr. Eidlitz, are: Vice Presidents, Walter J. Drury, Western Electric Company; William C. Peet, Peet & Powers Company; Theodore Beran, General Electric Company; Treasurer, John P. Ryan, Cleveland & Ryan, and Secretary, John MacIntyre.

From Cavite to Washington Direct

WIRELESS message from the Naval station at Cavite, P. I., addressed to San Francisco for relay to Washington was picked up in the Washington Radio Central recently and copied before the San Francisco operator indicated its receipt. Needless to say, it was not relayed to Washington. This message was copied without error over 11,500 miles of sea and land.

DON'T BOTHER

with sloppy, expensive, unreliable "A" batteries. Light the filaments of your tubes with a BILTMORE FILAMENT TRANSFORMER, directly from your house current. A. C. hum is practically eliminated, and on most sets, is entirely absent. State the tube you use, and the primary voltage (110 or 220 volts). Made for all tubes. If you are not absolutely satisfied in every way, we will gladly return your money.

Price, $3.50

BILTMORE AUDION PROTECTORS furnish absolute protection for all tubes. Price 25 cents per package.

FREE!

With each order. How to make the Wonder Set. This set with only a loop, brings the stations in strong enough for a loudspeaker. Our price for the complete parts, including "A" and "B" batteries, U. V. 201A tube, and loudspeaking unit, is twenty-five dollars. We also sell the set completely assembled.

BRAND NEW FADA ONE-SIXTIES. Regular price, $120. Our price, $105. We can give you equal reductions on any standard set or apparatus. Write us your wants.

DEALERS: Send for our proposition.

Radio Equipment of Capt. MacMillan's Arctic Vessel "Bowdoin"

By Sheldon Fairbanks

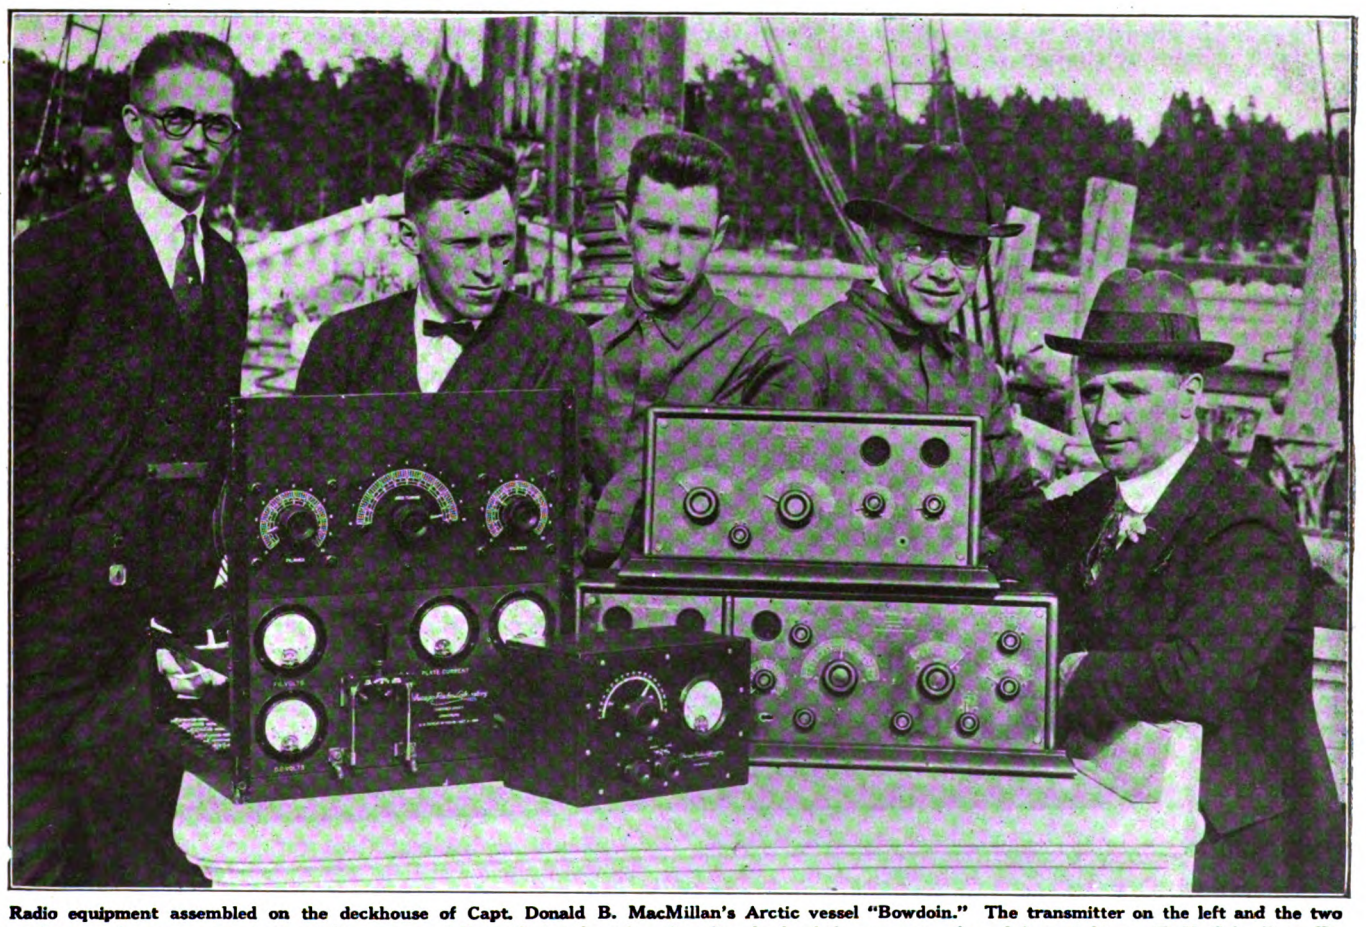
A Member of the Expedition

IN equipping Captain Donald B. MacMillan's polar ship "Bowdoin" with radio apparatus for its trip to the Far North on June 23 several interesting problems presented themselves.

The design and installation of the receiving and sending apparatus had to be of such a nature as to overcome the extreme temperatures to be encountered in the Arctic; also the schooner carries sails, and the rigging of the antennae presented some difficulty.

However, M. B. West, chief of the Chicago Radio Laboratory, who did the work, is confident that, for the first time, communication to and from the polar regions from the United States will be possible. This belief also is shared by the ship's operator, Donald Mix, and by K. B. Warner, secretary, and F. H. Schnell, traffic manager, of the American Radio Relay League, who have inspected the installation.

In the apparatus itself every precaution has been taken to permit of the expansion and contraction of the various parts to allow for extremes of temperature without interference with normal operation.



Radio equipment assembled on the deckhouse of Capt. Donald B. MacMillan's Arctic vessel "Bowdoin." The transmitter on the left and the two receivers and wave meter at the right were specially built for the trip. Standing back of the apparatus from left to right are F. H. Schnell, traffic manager, A. R. R. L.; Donald Mix, radio operator on the "Bowdoin"; K. B. Warner, secretary, A. R. R. L.; M. B. West, chief engineer of Chicago Radio Laboratory, in charge of installation, and Capt. Donald B. MacMillan, the well-known Arctic explorer.

How to Get Results Out of Your Receiver

By O. I. See

WHEN you get it home, take a screwdriver, a pair of pliers and a hammer and see if all the connections are firmly soldered. To do this, first take the screwdriver and pry under each connection. If it sticks, take the hammer and hit it a swat. If it still remains connected try to twist it with the pliers. If all the connections withstand this test, you may be assured that they were soldered.

Next be sure to try your bulb by shaking it violently to see if it is solidly constructed. Bite the tip off under water and test the vacuum. If the tube fills up and there is no air bubble in the tube there was a good vacuum in it.

Make sure that your condensers are not shorted. If one of the plates seems to be too close to another, take your hammer and proceed to straighten it. In order to prevent bending the plate next to it, take a wedge, and shove it between the bent one and the straight one and hit it a good, healthy blow. Be sure to test the bearings and take all the plates apart to dust them and then put them back being sure that you leave out two or three of the washers so that you will always have a couple on hand if you lose any.

Try out all the wires on your variometers and variocouplers. There is sometimes a loose wire. In order to test them grab each wire with a pair of pliers and give it a yank. If it doesn't stretch or break you may be assured that it is tight.

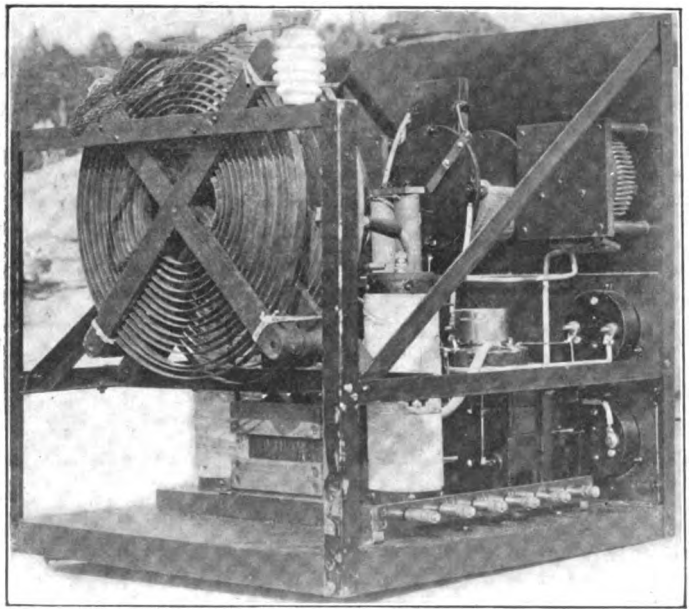
If you are using a storage battery it is always a good plan to let it stand a long while without water. This improves the plates as the acid gets stronger because of the water evaporating. It is also a good test of a battery to short circuit it with heavy wire. If the plates stand a good, long short circuit without buckling it was a good battery. There are very few batteries that will stand this test, so if yours doesn't, you may be sure that it is only average, and it is better to throw it away and get a new one.

What is a "Safety Gap?"

By a safety gap we mean a small air gap, generally put across the antenna and ground connection of a receiving set to allow any heavy electrical charge that gathers on the aerial to discharge without damaging the receiving set. The safety gap in common use generally consists of a minute spark gap, with the terminals about 1/50 of an inch apart. This small gap will not protect the set against lightning, but is used where there is a transmitter set nearby, and can be found on most all commercial sets.

(*Concluded from preceding page*)

The antenna is rigged to the two masts, with all four wires leading on a slant forward of the foremast, the lead-in wire being taken off one end of a small spreader swung about half-way between the top of the foremast and the tip of the bowsprit.



Rear view of the specially designed and built transmitter with which the "Bowdoin" will keep in touch with civilization during her trip to the Far North. It is straight C. W. with a wave length of 200 to 600 meters.

The lead-in insulator presented a peculiar problem, as with an interior temperature of 70 degrees above and a temperature outside of 70 degrees below a difference of 140 degrees is encountered. The slightest metallic connection between exterior and interior under such a great difference in temperature conducts the heat so rapidly that it is almost impossible to prevent ice collecting on the inner end of the conductor. Therefore the insulator itself was constructed of three concentric tubes surrounding a long, slender brass rod. The outer tube is of specially treated wood; the next is of hard rubber, and the inner tube is of glass.

Because of the obvious necessity of fuel economy the power for the transmitter is decidedly limited. The power plant consists of duplicate 850-watt Delco gas-engine-driven generators, connected to a 160-ampere-hour, 32-volt storage battery. This battery must carry the regular ship's light load in addition to that of the radio transmitter, which alone requires 50 amperes at 32 volts. Consequently one of the gas-engine-driven generators must always be kept in operation while the radio transmitter is working.

The failure of the 32-volt battery would mean a complete breakdown of the radio transmitter. In consequence this equipment was selected with great care, and a very complete set of spare parts, chemicals, etc., has been provided.

The small B batteries, so necessary as a part of the receiving equipment, also presented a problem. These small batteries seldom have a life of more than one year, and the expedition will be gone longer than that; possibly, with unfavorable conditions, two or three years.

Therefore the manufacturer provided a large supply of especially selected cells, whose behavior during manufacture was carefully watched so as to insure the longest possible life. These were selected by observing thousands of the cells during the regular course of manufacture and selecting only those which had characteristics indicating the longest possible life.

In addition to providing B batteries for a period of time longer than the possible life of the best selected cells a complete set of parts, with the necessary chemicals, are provided, with minute instructions so that additional batteries can be manufactured aboard as needed.

Every possible precaution has been taken to insure against failure from any preventable cause.

A Portable Single Tube Loop Receiver That Is Cheap and Reliable

By Robert L. Dougherty

THE ideal portable receiver for all practical purposes is the one or two tube reflex set, but there is the drawback of the additional expense of the transformers and their added weight, which, when considered in terms of pounds per hiking mile, grow heavier with each step. With this idea in mind it was thought possible to contrive some means of using a single tube on a loop without the necessity of relying upon reflex reception for medium distance.

Of course, it must be realized that a single-tube receiver of the type described here will not bring in stations 1,800 miles away, as do the single-tube, single-circuit sets using antennae and ground. But if reception over medium distance of, say, 50 to 200 miles is desired this circuit will give complete satisfaction if care is taken in its construction and operation.

In this circuit there is a decided change from most loop circuits, as a tuner is used. The tuner should be specially wound, and should be made in the following manner: Procure a tube 3½ inches in diameter and 5 long. If a cardboard tube is to be used it is best to thoroughly impregnate it with paraffine or beeswax to prevent shrinkage and consequent loosening of the wire. On this tube are wound the two coils, L-1 and L-2, as shown in the diagram herewith. L-1 is 32 turns of No. 22 DCC wire, tapped every four turns, making eight taps in all. L-2 is 12 turns of the same size wire, wound ¼-inch away from the first winding, and tapped at the eighth and last turn. Care should be taken to see that the two coils are wound in the same direction. In the winding of these two coils do not make the mistake of shellacing them to make them hold. If you want to be sure that the turns will not slip put a strip of adhesive tape along the tube, and when the wire is wound on top, the tape will groove and prevent any slipping of the wire.

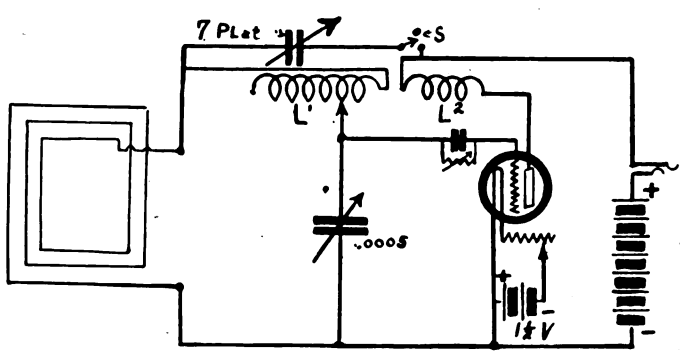
The seven-plate condenser is connected between the grid side of the loop and the switch S. This condenser is necessary to provide additional feed back when regeneration is found hard to promote with the plate coil. On local work this condenser will be found a great help in fine tuning, and on longer distance work will greatly increase the volume after the set is tuned in, although re-tuning may be necessary.

The variable condenser across the loop should be as shown in the diagram—one of .0005 mfd. capacity. It is not necessary that this be of vernier control, but, as with all single-tube circuits, it will help considerably in the tuning of the set. If it is not thought advisable to go to the added expense of purchasing one the simple button-dial control will suffice. The rest of the apparatus used is the same as in any set, and needs no explanation. As with any set that you construct you should only buy and use the best apparatus, and the wiring should be carefully insulated and soldered, particularly in a portable set, where it is subjected to the jars and jolts of handling and there is much more chance of breaking connections than in a regular table set.

The grid condenser should be .00025 with a variable grid leak. This is specified because of the fact that, if the dry-cell tube is used, it is generally very critical as to the leak value and much better operation can be obtained with one of the variable type.

When the set is assembled and you are ready for reception the loop is swung in the direction of the station desired, the tube turned on and the switch S placed on the open point. Then the condenser across the loop is turned until the station desired is heard. The switch for coil L-1 should be placed at about the middle tap, and the switch for L-2 is placed on the first or eighth turn. Then the condenser is again adjusted, this time also tuning with the coil L-1, and condenser switch S is placed in the circuit. Then the set is re-tuned as to the loop condenser. The entire tuning after this is done with the loop and the two condensers. If longer wave reception is desired, such as the 492 or 509 stations, the two coils are tuned up higher, using more inductance, and the same method of tuning is pursued. It will be found that, with some stations, better reception will be had by keeping the switch S on the open point.

The set can easily and neatly be mounted in a small case, such as is used for portable typewriters, and the controls neatly mounted on the outside of the box. In this way all the batteries can be mounted inside the cabinet, and with a portable loop such as described in the Vacation Number of



Schematic diagram of a convenient and easily made loop receiver that you can readily pack in one corner of your trunk and take away with you. The two coils L1 and L2 should be wound as specified in the accompanying text.

RADIO WORLD by Mr. Gordon a neat, compact and flexible loop receiver can be taken away with you on your vacation.

Care should be taken when mounting the tube to see that it is shielded from moving parts, otherwise you will arrive at your destination minus a tube and a good part of your temper. The current to run the set can well be furnished by a single dry cell for the filament and one of the small block-type B batteries for plate current, which will furnish enough current to operate the set over a period of two or three weeks if it is used three hours per day.

A good point about the receiver described is that, if an antenna and ground are available, they can be easily attached by simply using them in place of the loop, and, while the set is not designed for use with antenna and ground, good results can be had by their use, as it will then function as a single-circuit receiver.

With this receiver, as with any other, of course, the final results depend upon the operator knowing his set and how to work it. There can be no hard and fast rules for the operation of any set. No matter how definite the instructions are they cannot cover all the points that will be necessary when you are tuning in. The best way to operate a set is just like running a car, which is to practice until you can do it without thinking about it, and then it becomes automatic.

The Navy's Radio Central at Washington

By Carl H. Butman

THE new radio central office of the Naval Communication Service in Washington, D. C., is located in the big Naval Building at 19th and B Sts., near the Lincoln Memorial—sixth wing, second floor, rear, to be exact, and is approached through the several offices of the Communication Service, one of which is that of Rear Admiral Ziegemeier.

From this office issue all Naval radio messages from the Capital. The transmitters at Arlington, Annapolis, Sayville, and several smaller stations are controlled directly from keys installed here. Annapolis and Sayville are high-powered, trans-continental and trans-oceanic stations; and Arlington, which is a link in the long coastal chain, is used for medium district communication with Norfolk, Charleston, Key West, New Orleans and Guantanamo and ships at sea, over spark, arc and tube sets.

(C. International Newsreel)

Taking the romance out of radio by making it resemble a land telephone. The Radio Central control room in the Navy Department Building at Washington, D. C., where the channel lines of all the large transmitters of the United States are controlled. Chief Gunner J. J. Delany is at the board plugging in on the trunk lines which connect him with stations many miles away.

Long distance reception from the many outlying stations of the Naval chain is secured through six big receiving sets, known as RB type tube receivers, located in six separate rooms in different sections on the third floor of the Naval Building. From these sets leads run to the central switchboard and as many operating desks in the central office. The RB receivers pick up the messages on eight foot loops installed directly overhead on the roof of the building. These coils are directional and may be rotated from the rooms below by a rod when tuning in. Each set is put in operation, watched and shut down by a monitor engineer who makes continual rounds of the six separate rooms. A continuous watch is kept on these large sets, each covering a special station. One listens in on San Diego on 9,800 meters; another for San Francisco on 10,500; a third on San Juan on 8,785; a fourth for Balboa on 7,000; number five on French stations on 15,000 and number six is used for emergency, and experimental work and ships. Each inside wire leads from the switchboard to the operator's desk, where phones, typewriters and transmitting keys are installed.

The efforts of the Naval Communication Service are for reliability and efficiency in handling messages, and the sets and operators work on certain circuits all the time.

Two shorter wave sets, of SE 1420C-type, are installed in the central office, being connected with aerials on the roof above. These sets are used for receiving neighboring stations and ships on the Atlantic.

In Radio Central a busy scene confronts a visitor; some keys are clicking and some of the operators are typing messages from distant stations. Messengers come and go with dispatches from government officials to our representatives in foreign countries and our ships in the seven seas.

The long land line formerly used between the old receiving station at Bar Harbor and the Washington Office has been discontinued at large annual saving. Bar Harbor is now a coastal and compass station and handles no long distance messages, although the equipment is left in place in the event of emergencies or war requirements. Washington is literally the Naval Radio Central for the country today.

Radio and the Woman

By Crystal D. Tector

FRIEND HUSBAND told me the other day that he was going on a two weeks' fishing trip, and wanted to know if I would go along. I told him that I was perfectly satisfied to stay at home and buy my fish at the store, but that he could send me a couple of young trout to start a hatchery, so that next year he could go out in the backyard and catch all the fish he wanted. He laughed, and started in to pack his things, and then asked me if I minded if he took along my "pet Flewelling." Well, that was nerve if there ever was. Bad enough that I have to be a widow for two weeks without his taking the apple of my eye with him and leaving me all alone. I told him to get his own set out of the car and take that, but he said that he thought that mine was lighter and better. "You know I have to cross the lake in a canoe, and I don't want to take a chance of losing it." Oh, didn't I give it to him! Girls, I am going to start a club and propose that every woman build or get her own set, and never let hubby or his friends even listen to it or use it.

A school chum of mine whom I haven't seen in years dropped in the other day, and of course we started in to talk over old times and to recall all the old incidents of high-school days. After tea we went in to our "radio room," and she quite pleasantly remarked that she was taking the radio and advanced physics course at Barnard College. Well, you could have knocked me over with a half of a feather. "Why, G....., you used to hate elementary physics and math. and all those things." "I know that, K....., but you see I married a dear boy who is just up to his shoulders in radio research work, and I am studying it so that I can help him or work with him." Well, that goes to show that it is not only the men who can show how the wheels of progress turn and what makes a signal audible in the loud-speaker. I think that I will get hubby to let me take it up when I am not busy with other things. Then maybe I can write a book and become famous.

Tips on Loading Circuits for the Higher Wave Lengths

EVER since the new allocation of wave lengths a great howl has gone up from amateurs who have bought or built sets that will not reach the new higher wave lengths on which broadcasting is done. Quite a few have seriously considered junking their sets which have done such wonderful work for them in the past few months, and of course hate to do it, yet cannot think of any way in which to overcome the disadvantage under which they are working.

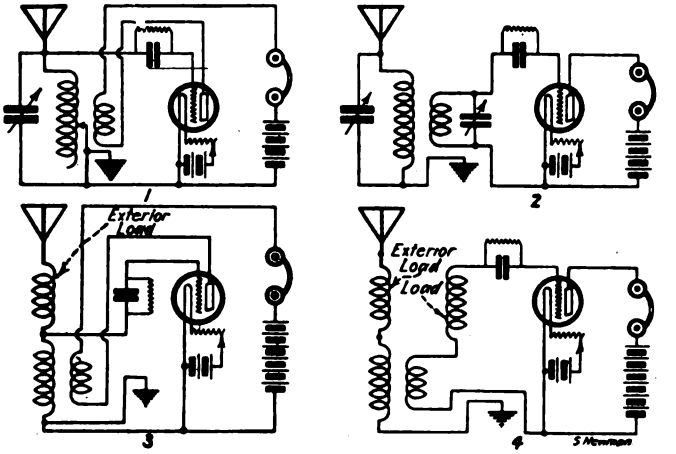
There is a very simple manner in which all of this can be overcome. It will also give the owners of such sets an insight into just what their sets really can accomplish.

No matter what type of set it is, it can be loaded up to meet the wave length of any transmitter, whether it be 492, or 12,000. Of course on the single circuit sets this is rather a difficult thing to do; that is, if you are considering loading it up to the real long wave lengths. But if you want to cover the broadcasters, and a little bit more besides, you can do it so easily that you will laugh at yourself for ever thinking that you were going to junk the set.

The first and simplest method of meeting the new wave lengths and one that is necessarily limited is to use capacity shunted across the main inductance of your set. By using a 43 plate condenser in parallel with your set, you can fully meet the new waves and yet you won't have to drill a single hole in your panel because all you have to do is hook a condenser across the antenna and ground posts of your set. Simple, isn't it?

If your set is a double circuit affair, it will be slightly harder, as both circuits have to be loaded. This can be done, however, by the same method—simply shunt your condensers across the inductances in both the primary and secondary.

The next, and probably the most efficient method, is to load the circuit by means of extra inductance. If you are handy and want to save money, wind a coil about four inches in diameter and six to eight inches long with a layer of No. 22 SSC wire, and tap it off every 20 turns for the first 100, and then every 40 turns after that to the end. That is a loading coil. Probably the most efficient of all, however, is the DL or honeycomb coil. In that case, it will only be necessary to insert an adapter in the antenna lead, and stick the coils in them. If it is a single circuit tuner, it will, of course, only be necessary to use one adapter. By this means you can get any desired wave, up to 20,000 by simply using the proper coils. If it is a double circuit tuner, it will be necessary to load the primary as well as the secondary, and if it is a triple circuit affair using a tickler and you want to go up beyond a reasonable amount (800-1000 meters) it would be best to load all the circuits.



Figs. 1-4. Various methods of loading both single and double circuits for higher wave lengths as explained in the accompanying text.

The accompanying diagrams show the four methods of loading the single and double circuit sets, both by means of capacity and by means of external loads which are the approved methods. The capacity method is only good for a very limited band, and a tuner that normally tunes to 400, when shunted by a 43 plate condenser will reach to about 700 efficiently. It is therefore seen that the best method is to load by inductance.

Radio Is Not a Summer Luxury—It's a Necessity!

DO you appreciate the value of your radio set as a summer necessity? If you don't you should, because it is just as much good in the summer as it is in the winter. The mere fact that the distance over which you can receive and the transmitters can send is shortened in a degree is of minor importance.

The main thing of importance is that you should and will use radio this summer. Of course, you may not like to take your three or five tube set away with you, but why let a little thing like that stop you? With 600 odd broadcasters working every minute of the day and night, you ought to be satisfied to take a single bulb set, or even a crystal detector set away with you, and get programs that should satisfy even the most critical.

The thing of main importance is that the set you take be portable and at the same time sensitive enough to get something worth while. Well, you have been trying out single circuit sets all winter—now put one of them into a small cabinet, incorporate a dry cell bulb, furnish the current from three or four flashlight dry cells hooked in parallel, with a small bloc type B battery, a good pair of phones, some wire for an antenna, and no matter where you go, you can keep in touch with the world through radio.

One of the main factors that has made summer radio possible is the small current dry cell tube. Heretofore it was necessary to have a storage battery or its equivalent to supply the filament. Now that is rendered unnecessary, because a small cell is all that is needed to supply such a tube for many hours.

When starting away, of course, one of the points to be considered is the antenna. You may be going camping, and if such is the case, just throw a stone with a string over a branch and pull up your insulated wire. Then when you decide to move all you have to do is take it down and roll it up. If you are going automobiling arrange your set in the back, on or under the dash, or along the running board. When you stop your car attach the wire to your set, and perform the same rites in installing your antenna as before.

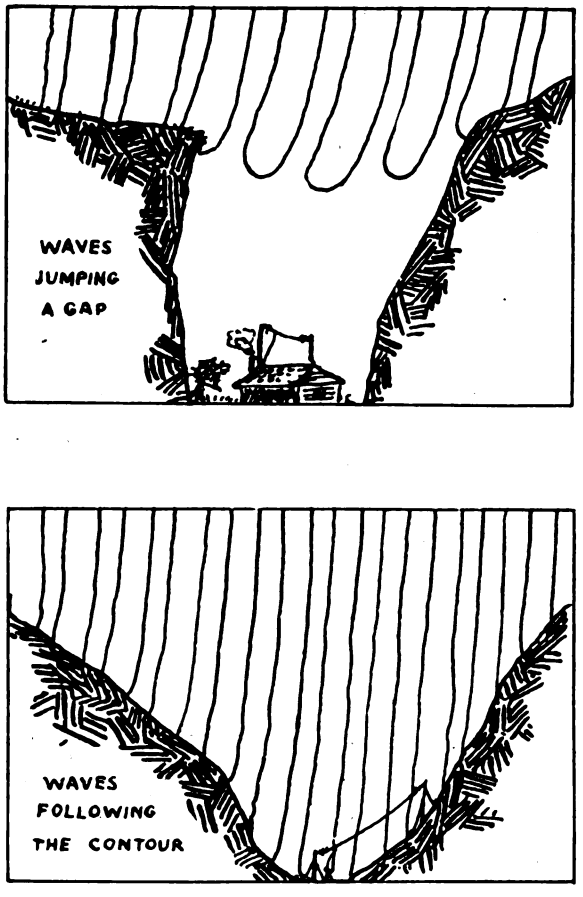
Conditions that Affect the Range of a Radio Receiver

By Kenneth Malcolm, A. I. R. E.

EVER since radio has come into popular use the universal questions seem to be "How far can my set receive?" and "How far can such and such a station transmit?" If a fixed and ideal set of conditions were available, the answer could be given with a fair degree of accuracy, at least theoretically, but practically there can be no definite answer because of so many variable factors that must be taken into consideration. There may be found cases in which two identical sets, with antenna in exact copy, located but a block apart, have given widely different results—one getting the most distant DX stations and the other getting nothing but the locals. The difference lay in the immediate environment.



Showing how radio waves will follow the topography of the country, but will jump sharp gaps between high walled places.

As an illustration of what is meant by variable factors, let us ask how far a locomotive whistle can be heard. Immediately the answer might occur "It depends upon the power of the whistle." Yes, that is true, but it also depends upon the nature of the surrounding country, the condition of the air, the direction of the wind, the direction the train is travelling, and the sensitiveness of the ear of the listener. In wide open country the sound could be heard much farther than in thickly wooded country or in the city. It could be heard farther if the air was clear and the wind blew in the direction of the listener; also farther if the listener's ears were very sensitive and the locomotive was approaching instead of going in the opposite direction. Any combination of these factors would produce different results.

In radio work we have even more factors to contend with. First of all comes the power of the transmitter and the sensitiveness of the receiver. Under given conditions an increase of power or an increase in the sensitiveness of the receiving set will give a proportional increase in range. A broadcasting station may have a maximum range of 1,500 miles; but this distance is covered only with a two stage radio frequency amplifier set at the receiving end. A single tube set might only hear it 200 miles and a crystal set only 30 miles. Then again, the reverse is also true; a single tube set might be rated at 500 miles, but only from a station with one kilowatt rating. A 500 watt station might only be heard one-half that distance.

Next in importance comes the immediate environment—possibly this comes even before power and sensitiveness. An aerial situated between tall, steel frame structures will not bring in as good results as one that is located in the open, for the grounded steel frames absorb a large part of the energy before the waves reach it. It is also manifest that steel buildings affect the quality and range of the waves from a transmitting station. A station that promised to be one of the best in the city had to be dismantled, or at least used only for experimenal purposes, because the steel in the building in which it was located and in neighboring buildings, had the tendency to distort the waves thereby preventng faithful transmission.

A curious case was reported quite recently by the army. A fine transmitter had been erected on a mountain after much hard work. They were able to radiate a good 2 kilowatts, but try as they might they could not reach their home station but fifty miles away. After much reasoning and an extended search they found that an iron mine in the vicinity was the cause of the trouble. It simply drained all the radiated energy into the earth.

Radio waves will pass much more readily over water than over land, the degree depending to some extent on relative dryness of the land. Then, too, there are fewer obstacles in the way when the waves pass over water. Ships at sea copy "press" many times over a distance of 1,500 miles with a comparatively ancient crystal set.

The condition of the atmosphere is a great factor that cannot be disregarded, for this is the operator who can at will switch you to either "local" or "long distance." It was the atmospheric conditions that enabled most of the long distance records to be made and broken. When you can get Davenport one night and only Pittsburgh the next night, you can in most cases blame it on the weather. Clear air is the best air; and water and dust particles are detrimental as they tend to absorb part of the energy of the advancing waves. Reception cannot be carried on as well in the day time as in the night because the sun's rays ionize the air particles and render them conductive, hence absorbent.

Considering all the variable factors it is not quite

A Radio Set Personifying Portability

By Harvey Graham

WITH every amateur striving for portability and convenience in radio sets to take away for the summer it is not surprising that some very fine examples have been evolved. As far as portability goes that is very easy; but, for fine workmanship and novel arrangement, a portable set made by C. A. Pezet, of 46 West 65th Street, New York City, is the neatest and most compact yet seen.

With this set, the circuit and picture of which is shown herewith, several outstanding features at once make themselves apparent. One is that the set will operate without any antenna. It has been demonstrated, and exceptionally clear reception recorded, using the center post (No. 3) with a ground, such as a wire in a small lake, or even hooked to a telephone, or clipped on the foliage of a tree. The circuit

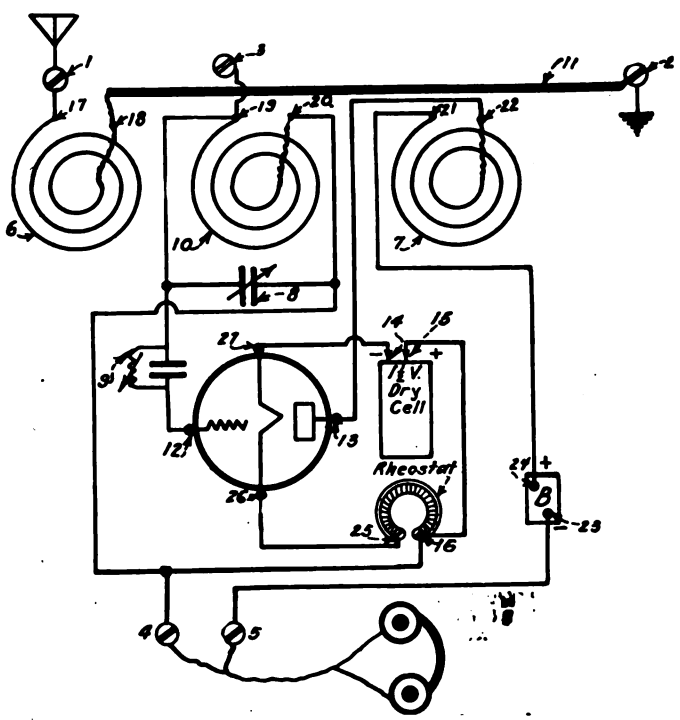

Diagram of the Pezet set using the specially made spiderweb coils which make its use without antenna possible.

has so many adaptabilities that it is possible to take it any place at all. You can use your bed-spring, or the frame of the car, or just drive a wire into the ground. It can also be operated at a regular three-circuit set with antenna and ground. When antenna is not employed the primary circuit is not used, and simply acts as a stabilizer and vernier tuner. Thus exceptional sharp tuning and selectivity is possible.

The secret of the whole set lies in the special spiderweb coils, wound with litz wire on a special former. The originator of the circuit spent many months before he finally determined the correct amount of inductance to be placed on each before it would work satisfactorily.

As can be seen in the drawing, the set, when used with antenna and ground, is an ordinary three-circuit spiderweb tuner, the tuning being accomplished by means of varying the coupling of the tickler and primary. It is when the third post (3) is used that the special advantage of this circuit is brought forth. When this is done it is seen that the ground connection is made to one side of the spiderweb that goes to the grid condenser and grid leak. Then, of course, the primary is of no use, the entire tuning being accomplished with the condenser across the secondary and the coupling of the tickler. The tuning is remarkably sharp and wonderfully clear reception is had, free from all distortion and noise. If interference is noticed tuning is done

The portable set being used by simply attaching a wire from the center post to the foliage of a convenient bush.

with the primary, and it stops, having been fully absorbed.

This entire set can be easily accommodated in a Corona typewriter cabinet or carrying case, as shown in the accompanying illustration, and because of the fact that a variable condenser of the book type is used the set can be accommodated, batteries and all, and there is enough space for two sets of phones and a spare box for odd parts, such as screws and clips. Enough wire can be carried on a small spool to form a convenient antenna should it be so desired.

When considering the work that this little set will accomplish and the small space it takes up, as well as its additional feature of not even needing an aerial for efficient operation, it can be claimed that the "essence of portability" has been reached.

(*Continued from preceding page*)

fair to ask how far a certain set can receive. The only real way to find out is to try it under the actual conditions in which it will be eventually used. Even then, you will find that every set has what we might call a reliable and variable range; one that can be depended upon under all conditions, and a second that will work only when things are most favorable.

By reviewing the points mentioned, it may be inferred that a given receiving set will have its greatest range when the air is clear, at night, over water, and the transmitter is of the highest power and in the most favorable local environment. To the degree in which this perfect state of affairs is an actuality, will the goal of maximum possible range for a specific set be heard satisfactorily.

If your set does not give quite as satisfactory results as you might expect, don't condemn it immediately but look around and see if there is not some condition which you might better. Possibly a little change in the location of your aerial might transform a failure into a success. When on the hike keep to the water, the open spaces, and the mountain tops and stay out of the walled-in valleys.

More New Broadcasters Assigned Wave Lengths

WASHINGTON, D. C.—Five new Class A stations were licensed during the ten days ending May 31, three Class C stations transferred to Class B status and 28 Class C stations transferred to Class A with specific district wave lengths. Class B stations now number 39; Class A, 146; Class C, 405, and Class D, broadcasting experimental, 1; a total of 591 stations.

Five New A Stations Licensed

Call	Station	Frequency Kcys.	Wave Length Meters	Power Watts
WABI	Bangor Railway & Elect. Co., Bangor, Maine	1,250	240	50
WCBA	Haimbach, Chas W., Allentown, Pa.	1,070	280	5
KFIO	North Central High School, Spokane, Wash.	1,190	252	50
WABJ	Radio Laboratories, The, Dean Bldg., South Bend., Ind.	1,250	240	10
KFIK	Gladbrook Electric Co., Gladbrook, Ia.	1,280	234	20

Twenty-eight Transferred from Class C to Class A

KFAV	Abbot Kinney Co., Venice, Calif.	1,160	258	5
WGAW	Albright, Ernest C., Altoona, Pa.	1,150	261	100
WOAG	Apollo Theatre, Belvidere, Ill.	1,340	224	20
WLAS	Central Radio Supply Co., Hutchinson, Kansas	1,230	244	20
WBU	City of Chicago, Chicago, Ill.	1,050	286	500
KFAT	Donohue, Dr. J. T., Eugene, Ore.	1,090	275	50
WPAJ	Doolittle Radio Corp., New Haven, Conn.	1,120	268	10
WDAK	Hartford Courant, Hartford, Conn.	1,150	261	100
KFAU	Independent School Dist. of Boise City, Boise, Idaho	1,110	270	10
WSL	J. & M. Elect. Co., Utica, N. Y.	1,100	273	100
WCAY	Kesselman O'Driscoll Music House, Milwaukee, Wisc.	1,150	261	500
WGAL	Lancaster Elect. Supply & Const. Co., Lancaster, Pa.	1,210	248	10
WKAX	Macfarlane, W. A., Bridgeport, Conn.	1,300	231	15
KFEV	Radio Elect. Shop, Douglas, Wyo.	1,140	263	100
KDYM	Savoy Theatre, San Diego, Calif.	1,190	252	100

Three Class C Stations Transferred to Class B

WBAV	Erner & Hopkins Co., Columbus, O.	770	390	500
WOAI	Southern Equipment Co., San Antonio, Texas	780	385	500
WOAW	Woodmen of the World, Omaha, Neb.	570	526	500

Radio Amateurs of Great Value in War

THERE is practically no end to the possibilities of radio for military use, an officer of the Signal Corps stated recently, adding that young men who wish to serve their country can do so in no better way than to become qualified in radio and to join the National Guard or Signal Reserve Corps of the Army.

There is no more interesting study for young Americans, he points out, than radio. It need not be taken up as a profession, but merely as a part of one's general education. Every one should become familiar with radio in "this electrical age," the officer insists, explaining that some of our leading radio engineers like "Eddie" Armstrong, started as amateurs.

As an instance of the work of former amateurs who served in the Signal Corps during the war, it is said that 73 per cent of the 400 radio men engaged in intelligence work were ex-amateurs. Not a single "leak" occurred in the service, which intercepted 73,000 enemy messages and recorded 175,000 bearings on enemy radio stations. The country and the Signal Corps is greatly indebted to these amateurs for their war work.

Although little is known of the work of the radio intelligence section of the Army during or since the war, it was one of the most spectacular. Radio direction finders were placed all along the lines, at a distance of about five miles from the actual front and spaced about twelve miles apart. These receiving sets located the enemy stations in operation, recorded their bearings by means of directional coils, not unlike modern radio compasses, and forwarded the bearings to headquarters where they were plotted on maps. The reports from many American radio observers enabled the staff to keep an accurate check on practically all the German stations all the time.

Other radio receiving stations at Army Headquarters intercepted and copied all enemy code messages and telegraphed them back to General Headquarters where code experts worked them out, giving the staff valuable information as to the movements or intentions of the enemy.

On one occasion, when the Germans were planning a big offensive, the code all along the line was suddenly changed. The old code, known by the Americans for some time, became valueless. But one German officer could not decipher a long message sent him in the new code and asked his commander to repeat it in the old one. This was done and as the American intercepting stations copied both messages, the staff of experts at headquarters soon had a fair solution of the new code, which they eventually worked out in its entirety. The repetition of the message in both codes was more than they hoped for, and when the new code was transmitted to the French and British headquarters, the American radio intelligence service was credited with a big "scoop."

Many times, it is reported, enemy messages were intercepted, decoded and rushed to the troops at a threatened front in time for them to prepare for the projected attack.

Wonderful results were also accomplished by our advance listening-in stations in front line dugouts and trenches, where amplifiers with wires radiating to grounds in no-man's land were placed. Sometimes they were actually tied in on enemy phone lines. These stations picked up enemy phone conversations by induction, enabling our operators to copy orders and messages.

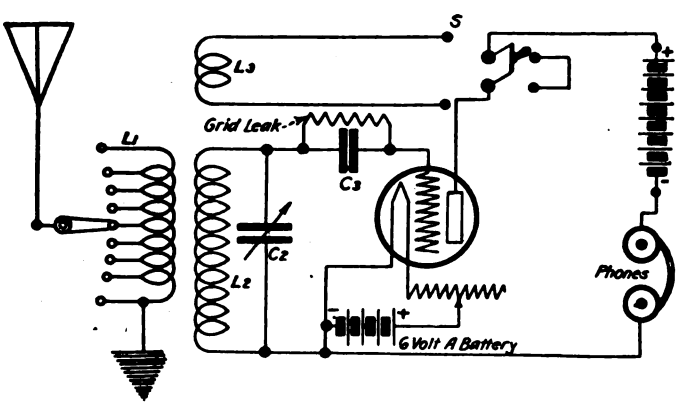
RADIO PRIMER

For the New Army of Radio Beginners

By Lynn Brooks

REGENERATION: In order to understand regeneration it is first necessary to have a knowledge of how the ordinary vacuum tube works in the reception of signals. In the regular two-circuit tube set the energy is picked up by the primary circuit, consisting of antennae, primary coil and ground. Due to the proximity of the secondary coil there is a current induced in the secondary or grid circuit. Immediately there is a large variation of the current in the plate circuit, due to the fact that the grid, being charged positively, allows the negative electrons to flow to the plate. This circuit is supplied by the high voltage battery, and consists of the phones, high voltage battery and plate of the tube, and the filament of the tube, which is connected through the circuit from the minus of the high voltage battery. At the second when the grid is charged the current flow in the high voltage battery circuit (commonly called B circuit) is at its peak, and an exact reproduction of the signal emanated is heard in the phones. The strength of this current flow can be controlled in a small way by the heat of the filament. Up to a certain point (called the "saturation point") the filament throws off electrons in direct proportion to the amount of current flowing through it. After this saturation point is passed it will not throw off any more than a certain amount, and frequently the electron flow jams and ceases. These electrons, being negative in action, allow the current to flow in the plate circuit when the grid is positively charged.

Now if we introduce a coil in the plate circuit and couple it to the secondary or grid coil we can get what we call regeneration. A signal is impressed on the grid in the manner mentioned, and a variation of the current in the plate circuit takes place. The extra coil being in the plate circuit, whatever current flows in the plate circuit must of necessity flow through the coil. This coil is held in inductive relation to the grid or secondary coil. It is evident, therefore, that there will be a transference of energy from the plate coil to the secondary or grid circuit which will tend to back up or reinforce the original current in this circuit, causing a much greater amount of current to flow in the plate circuit than originally. This action occurs many times until the point is reached at which the tube oscillates itself, at which time the original signal tone is lost and a mushy note takes its place in the tube. In controlling regeneration the amount of coupling used between the plate coil (tickler) and the grid coil (secondary) are the controlling features in the amount of regeneration or feed back, and the best point in this self-amplification scheme is the point at which the tube is doing its utmost just below the oscillation point, at which it "spills" over. When this point is reached the amplification due to regeneration is highest. To illustrate this action the hook-up herewith is given. It is a combination regenerative and non-regenerative hook-up. The switch in the plate circuit is the factor controlling the non-regenerative and regenerative hook-ups. By following the explanation given above the principle of regenerative and non-regenerative circuits can be easily followed. When the switch is on S the circuit is regenerative, the feed-back coil (L-3) of the plate circuit being in the plate circuit, and re-transferring the plate circuit energy back into the grid circuit to strengthen the original current in the circuit. When the switch is in the opposite position the circuit will not regenerate because the plate circuit has no means of feeding back.



Combination circuit illustrating feed-back and straight circuit. When switch is on S circuit is regenerative.

ADVANTAGES OF REGENERATION: It is possible by means of regeneration to get an enormous amount of self-amplification on one tube. With some signals, especially when the set is tuned properly, it is possible to receive signals with an amplification of one stage of audio-frequency amplification, and sometimes even more, all depending upon the manner in which the regeneration is handled. This is partly due to the fact that the principle of radio-frequency amplification is brought into play because the signals in the plate coil are superimpressed upon the signals in the grid circuit, which are of radio-frequency.

The Daily Paper Radio Situation in New York City

The purchase by Frank A. Munsey of the New York "Globe" has stirred up things considerably as far as radio and the daily papers are concerned. Mr. Munsey, who thinks nothing of killing a publication that no longer interests him, divided the various "Globe" features between the "Sun" and the "Evening Telegram." The "Sun" gets the radio section and it is understood that for the time being at least the radio staff will remain intact. The "Evening Mail" expected to make considerable capital out of the fact that the "Globe" as a separate entity was no more. This gladsome view, however, was changed when the "Evening World" announced that it would almost immediately start a radio section to go with its Saturday edition. This move of the "Evening World" is really a triumph for radio. The Pulitzers have always figured that the "Morning World" and "Evening World" were primarily for news and while they contained features, they are not regarded as feature papers in the same sense as the "Globe" was. For instance, some years ago, an attempt was made to have the "Evening World" establish a theatrical department on the order of Zit's department in the "Evening Journal," but Ralph Pulitzer put down his foot hard and declared that he would not consider the proposition. The determination of the "Evening World" therefore to publish a radio section is ample proof that the publishers have made a thorough investigation of radio, have made up their minds that it is here to stay, and that it is a good circulation getter.

All of which is good grist for the radio mill—for the more daily papers that are devoted to radio, the better it is for the whole science, art and business of radio, even tho these papers cannot be expected to cover the field outside their own distribution limits.

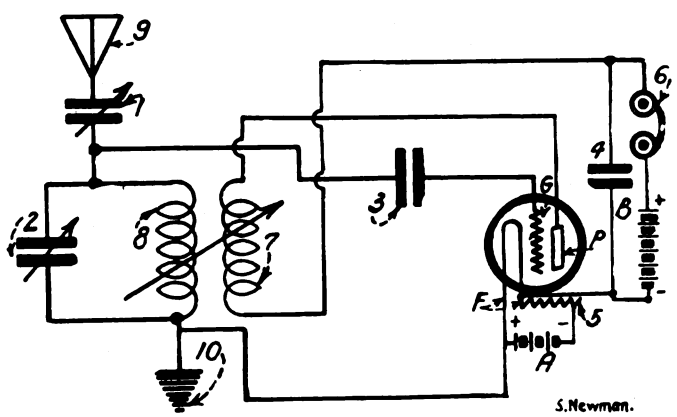
A Portable Set with "Roller Skate" Attachment

(*Concluded from front cover page*)

up in the space between the panel and front cover. The filament rheostat can be seen in the lower right hand corner where it connects directly to the A battery. It will be noticed that the phone terminals are also located where the shortest possible wires serve for connections. The right hand dial controls a vernier condenser connected across the primary coil. This condenser is made of two circular brass plates about four inches in diameter, one screwed onto the back of the panel and the other soldered to the head of a ¼-inch stove bolt which is threaded through the panel. The dial is attached to the opposite end of the stove bolt. The one plate, therefore, rotates with the dial and owing to the threaded support moves toward or away from the stationary plate as indicated in the sketch. A spring contact rubs against the movable plate while the other connection is attached to the



Circuit used by Brown in constructing his portable set. (1) 43 plate condenser. (2) Special 2 plate vernier. (3) Grid condenser (no leak). (4) Phone condenser. (5) Filament rheostat. (6) Phones. (7) Secondary of coupler. (8) Primary of coupler. (9) Antenna. (10) Ground.

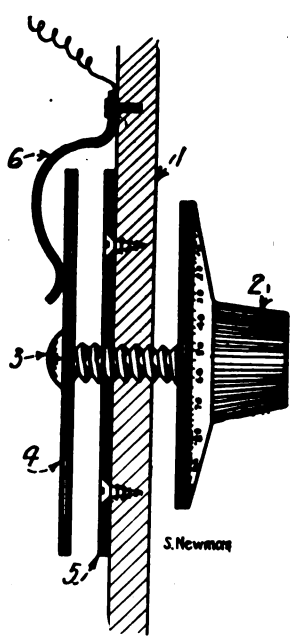
(*Concluded from cover page*)

stationary plate. This condenser serves the same purpose as the ordinary vernier making it possible to choke off WHN and pick up WGY or vice versa. We have also tuned out both WJZ and WEAF and picked up WGY without the usual squeals and yowls. This, however, requires considerable patience as one must hold one's breath and refrain from the slightest movement. Body capacity, of course, has a decided effect owing to the wood panel, used for its beautiful, ingrain effect. If when approaching the panel, Uncle Roxy of Capitol fame, comes in funnier, this indicates more capacity is required on the condenser. If it squeals and you miss one of his jokes turn it the other way quick and there you are. We have just been listening to him and his Mike broke down under the strain. Even the vernier condenser can't help that. The left hand dial controls the 43 plate condenser in series with the antenna. Most of the tuning is done with this dial. The center dial controls the rotor or tickler coil and thereby the amount of regeneration.

Needless to say, a WD-11 tube is used with a 1½-volt A battery. The 45 volt B battery is located in a separate compartment. A 1½-volt flash light bulb and socket are attached to the positive terminal of the B battery as a fuse. This ten cent ballast bulb is not even lighted by the small amount of current drawn from the B battery but would at once burn out should any wires be accidentally crossed. This would save my WD-11. The home made variocoupler is of the basket variety. Exactly 60⅓ turns are used on the rotor or tickler coil and also on the primary which is the secondary as well. You may find that 49½ turns work equally well if too many turns are not wound on the water pipe ground connection. We are originally from Missouri and have very little faith in the electronic theory. At any rate, a little experimenting will prove that the correct number of turns may be used to tune from 200 to 600 meters without taps or switches. A condenser from an automobile ignition coil is used in place of the regulation grid leak and condenser.

Now the "Roller Skate" attachment or the little Saxon roadster as it was once known, comes in very handy as a counterpoise. The set was in actual operation when the photo was taken, the frame of the "Roller Skate" being used as a ground. WEAF 25 miles away came in loud enough to be heard three or four feet from the phones. We measured it with a steel tape to verify this statement. The tape is in my right rear pocket. WJZ or WEAF were tuned in or out at will. The 150 ft. roll of bell wire was used as an antenna. One end tied to a stone was thrown over a nearby tree. We would suggest tying the stone very carefully and keeping the wife and child well out of the way. Also do not attach the wire to the set till the stone stops—otherwise the concert may be all off. A sour high C caused the wife's sad expression.

To sum up, allow me to say this is a real Hum Dinger portable set. The batteries, phones, dials, antenna, etc., can all be enclosed and protected by the



Constructional details of the special vernier condenser used in the Brown circuit.

cabinet which is only 8x8x14 inches and weighs less than 20 lbs. When touring with the Saxon, the tube is removed from the socket and carefully wrapped in flannel if the weather is cold. This also obviates the necessity of shock absorbers on the car. The set will operate six pairs of head phones in series. We have attached three of them to an extension line running to different parts of the house and discovered that we could telephone one another while listening to the radio concerts.

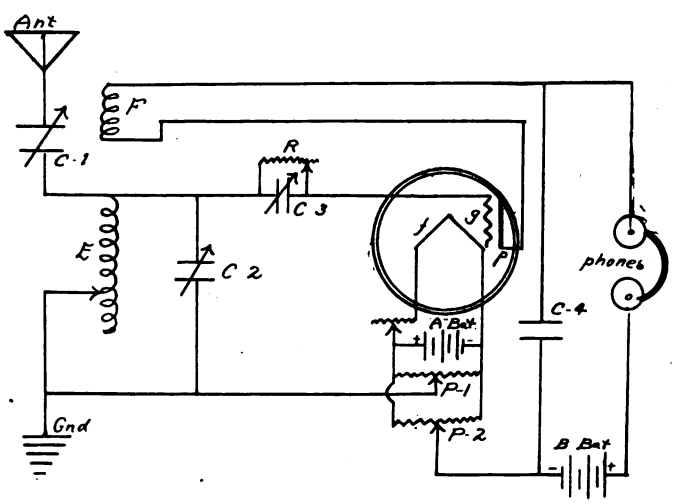
An Extremely Selective Single Circuit Receiver

By C. White, Consulting Engineer

THE general tendency in receivers has been simplicity in control. In fact, the general demand has been for a radio set that would be selective and tune with only one dial. The combination of simplicity with reliability is not an easy matter, since certain advantages must be sacrificed in order to make a receiver simple, and it is a general rule that this is done at the expense of reliable operation. One of the most familiar simplified circuits is the well-known "flivver" circuit. Such a circuit tunes in with a single dial, or can be so constructed and operated to do so; but the secret of the whole circuit lies in a constant critical value of grid leak resistance. If the atmospheric conditions, such as moisture, change it is almost a sure guess that the value of your grid leak will change. In fact, I have seen flivver sets that work splendidly one night and on the next, for some reason, it would be almost impossible to secure any reliable results. Then after fooling around with the grid leak the circuit could be restored to its normal working condition. I am not in any way trying to hit the flivver circuit in the least, for I have heard many such circuits, and the results obtained on many were nothing short of remarkable considering the fact that they are simplicity itself. I am simply bringing forth the fact that many receivers that apparently have only a few external adjustments really depend upon other adjustments, such as the grid leak, to keep them in normal condition. Then, again, if a circuit only affords one method of tuning in, how are you going to tune in when interference is bad? There is only one method with a single control tuning set, and if conditions are bad when it is desired to have clear reception there is no other dodge or means left. With the type of circuit outlined in this article there are about twelve different ways to tune in a station, and if perchance poor results are obtained with two or more methods you still have some others left to try. In addition this set affords ample opportunity to experiment and find out just what the various controls do and how they alter reception under certain conditions. It will elevate the average amateur who builds it to the plane of an experimenter, and will not allow him to remain a dial turner until he sees fit to purchase another outfit.

Aside from the fact that the multiple controlled set allows flexible tuning and experimentation it is just as simple to build as any set, only it requires a few more parts. But when all its advantages are summed up it is well worth the trouble and expense of the extra parts. In fundamental theory the circuit is nothing more than the ordinary single-circuit regenerative with a tuning condenser C-2 shunted across the tuning inductance coil E. We can tune in by means of C-1 and E, or by means of C-2 and E, or, better still, by means of the three together. When using the latter method it is better to approximately tune in with C-1 and E, then use C-2 to put on the fine touches. In constructing the receiver you should take care to see that the movable plates of the condenser, C-2, are connected into the filament or ground side of the circuit instead of the grid side. By so doing it is possible to cut down body capacity to a minimum, since the shaft of the condenser is at the same ground potential as the operator's body. A variable grid leak resistance makes it possible to clarify the signal and at the same time raises the volume. You cannot imagine just how important this apparently small part of the set is on the quality of reception. The variable grid condenser allows still further manipulation of the grid circuit constants, and by its adjustment the best detecting portion of the tube's characteristic is assured for use. The potentiometer P-1 renders a vernier action on the amount of regeneration and stability of the circuit. At first the action of the potentiometer P-1 will seem to only increase and decrease the volume, but by careful adjustment of the amount of regeneration on distant signals it is possible to use P-1 to an advantage in holding the tube stable and prevent it from falling over into oscillation. The action of P-2 is somewhat similar to the action of P-1, but it is not so fine. But by the careful use of the two we can assure smooth regeneration, accompanied with the minimum amount of tube noises.

The constants for the circuit illustrated are as follows: The condensers C-1 and C-2 are 11 or 13 plate air variables, with some sort of vernier either built in or externally



A single circuit set can be made super-selective by the use of two potentiometers as shown in this drawing.

connected. The coil E is the stator of a 180-degree coupler, and the coil F is the rotor. By varying the coupling smoothly through 180 degrees action of the coupler it is quite possible to vary evenly the amount of regeneration. The condenser C-3 is a three plate air variable, such as is commonly employed as a vernier. This condenser should have a maximum capacity of .0003 mfd. The leak resistance R should be one of the few panel types on the market. The panel mounting of this important part of the circuit permits ease in operation, thus obviating the necessity of diving into the wiring of the set to vary the leak resistance. The potentiometers P-1 and P-2 should have a resistance of 300 or more ohms. apiece. The condenser C-4 is a fixed mica condenser of .0025 mfd. capacity. In wiring up the set try to keep the grid wire as short as possible. This means that the tube must be mounted very near the variable grid condenser C-3.

For the amateur who really wants to know what varying the constants of the different parts of the circuit will do, this receiver allows ample room for successful experimentation, and still allows the receiver to be kept in the panel form. It is the ideal set for the amateur who likes to find out for himself the how and why of things.

Latest Offical List of Broadcasting Stations in the United States

FOLLOWING is the second installment of an official list of commercial broadcasting stations in the United States as issued by the Department of Commerce, and is continued from last week's issue. The list will be continued in next week's RADIO WORLD.

As new allocations of wave lengths to stations now operating on 360 meters are made by the Department of Commerce, the changes will be published by RADIO WORLD.

Readers who save these installments will have a complete list of broadcasters with their station calls, location, frequency, wave lengths and power.

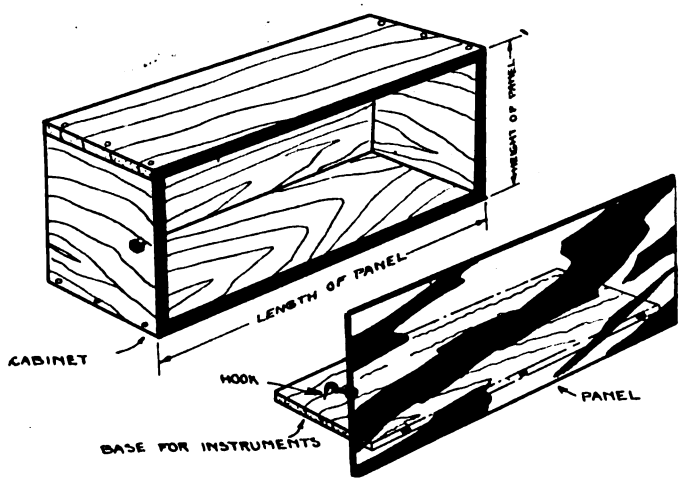
A New Idea in Cabinet Construction

By Arthur S. Gordon

THIS original idea in cabinet construction is the logical outcome of the radio amateur's need for plenty of room while testing or adjusting his receiver. Ordinarily, when something goes wrong with the outfit, the enthusiast raises the lid of the cabinet, puts his hand down between the tube socket and the rheostat and forthwith tries to tighten a nut or start a machine screw in its lawful thread. It can't be done. In the subsequent process of trying, however, the radio amateur becomes very much peeved, to say the least. Before the operation is over he has probably pulled the entire cabinet apart, leaving only the base and the panel front. He would have torn



An idea in cabinet construction that will tend to improve the appearance of your set.

them away also if there were no instruments attached to them.

This mad wrecking of material in order to reach parts in need of repair is not necessary if the cabinet is built along the lines suggested herewith. All that is necessary is to release two hooks, take a firm hold upon the panel, pull it forward, and the entire receiver, from the vario-coupler down to the last microfarad of condenser capacity, will leave the dark recesses of the cabinet and come forth into view.

Looking at the sketch which accompanies this description the reader will note at once that the base of the cabinet is entirely separate from the base on which the instruments are mounted. This separate base is the secret of the idea's successful application. To it is fastened the panel and upon it are mounted all the instruments that formerly found a place on the bottom board of the box. The double base is of such a size that it will readily slip inside the completed cabinet. It should be made of wood, about ½-inch thick, and, when the radio receiver is completely assembled, should rest upon the base of the cabinet.

The panel is fastened to the instrument base by three screws. It is not necessary to further reinforce the base by either a brace or a brass standard, for when the instruments are all in place the unit will be found to be firm and solid. The panel is secured to the cabinet by means of either hooks or screws. Hooks are shown in the sketch, and are recommended because of the greater ease with which the panel may be released from the cabinet. There is no real objection to using screws, however, aside from the extra holes needed in the face of the panel.

The cabinet is a solidly constructed box, built so that its outside dimensions are the same as those of the panel. It is made of wood. There are no hinges necessary. The depth may vary according to the needs of the builder, but six inches is the average dimension. One feature of this slip-in-and-out arrangement that will not pass unappreciated is that the cabinet can be screwed down to the radio table. When firmly fastened in this way it provides a safe receptacle for the radio receiver, mounted on the panel and separate base, as here described.

Latest Radio Patents

Method of Secret Signaling

No. 1,454,532: Patented May 8, 1923. Patentee: William E. Beatty, Bayside, N. Y.

THIS invention relates to carrier wave signaling in which messages are transmitted as modulations of a carrier wave.

An object of the invention is to transmit the modulated carrier wave in such a form that it will be unintelligible unless received by specially designed apparatus, such as disclosed herein.

When a message in the form of a carrier wave is sent out from a radiating antenna system, this message is liable to be intercepted by any one who has a radio receiving system at his disposal. It was early recognized as being desirable to send a radio message in such a form that it would be unintelligible, or would not be received at all, unless specially designed receiving apparatus were used. Former carrier wave secrecy systems, for the most part, are open to the objection that the specially designed receiving systems include a motor which must be kept in synchronism with a similar motor at the sending station.

Fig. 1.

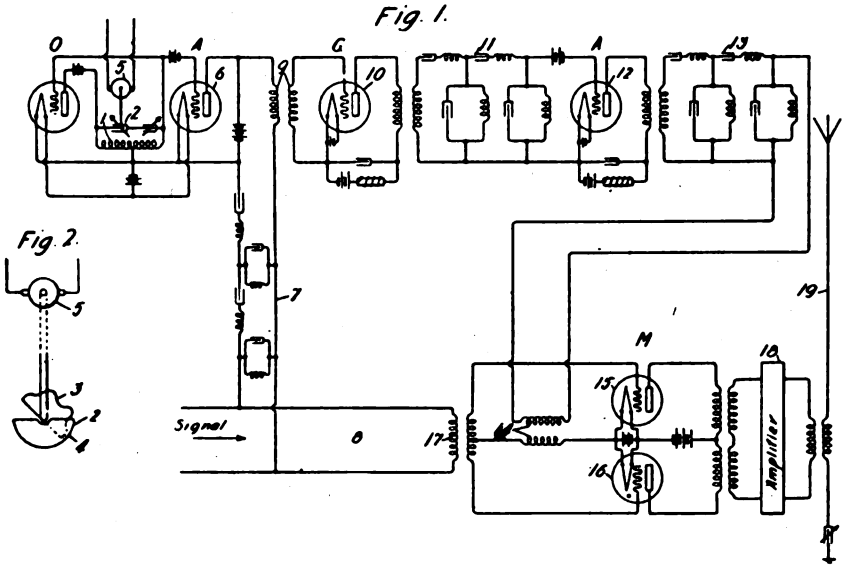

Fig. 2.

William E. Beatty's method of producing modulated signals which cannot be received except on specially designed receivers. He accomplishes it by the use of a pure modulated wave component having side frequency previously determined. A mechanical means is also used which consists of the rotation of a specially designed condenser at certain speeds.

This objection is not applicable to the present invention, according to which a method of and means for secret signaling are provided, in which a proper phase relation between the currents at the sending and receiving stations is maintained without the use of synchronously driven moving parts.

In order to get the modulated wave into a form that cannot be handled by ordinary receiving apparatus, advantage is taken of a previously proposed scheme, according to which the unmodulated components having carrier frequency p may be suppressed, so that a pure modulated component having only the side frequencies $p+a$ and $p-a$ may be transmitted. In this case a is the instantaneous frequency of the modulating currents. If only the side frequencies $p+a$ and $p-a$ are transmitted, this gives an element of secrecy, as this message is unintelligible unless combined at the receiving station with locally generated oscillations of frequency p. In a manner analogous to the production of beats in sound waves, the combination of currents of frequency p with currents of frequency $p+a$ for instance, gives the difference frequency a corresponding to the signal which was sent.

According to the present invention the unmodulated currents are likewise suppressed, so that only the side frequency $p+a$ or $p-a$ or both are transmitted. Instead of keeping the carrier frequency p constant, however, as previously proposed, the present invention provides for continually changing the value of the carrier frequency p while signals are being sent.

If in this case an intercepter attempts to get the message by combining the received waves with the locally generated oscillations of a constant frequency, he will hear in the receiver a noise produced by currents having a varying frequency equal to the difference between the frequency of the locally generated oscillations and the frequency of the side band $p+a$ or $p-a$, where p is continually changing. Currents of this character give rise to a siren effect in the receiver and the signal is not intelligible. The value of the carrier frequency p transmitted is varied rapidly and in an irregular manner, so that an intercepter would be confronted with the problem of similarly varying the frequency of the locally generated oscillations before the received message wave could be rendered intelligible.

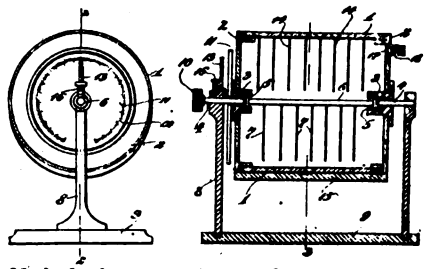
The manner in which the present invention provides for varying the locally generated oscillations at the receiving station in the same manner as the frequency of the carrier oscillations at the sending station, without the use of synchronous motors, will be described in connection with the drawings in which:

Fig. 1 illustrates a radio signaling station; Fig. 2 discloses the motor-driven condenser blade, having an irregular shape, that may be used in connection with an oscillator to provide a carrier frequency which varies in an irregular manner.

Electrical Condenser

No. 1,452,610: Patented April 24, 1923. Patentee: Morris Kloaner, New York, N. Y.

THIS invention relates to electrical condensers, and has for an object the provision of an apparatus of this character which is of continuously variable capacity whereby the tension may be varied to meet numerous requirements; a further object being to provide an apparatus which is of such air-tight construction as to be capable of containing either compressed air or any adaptable gas capable of being used in electrical condensers.



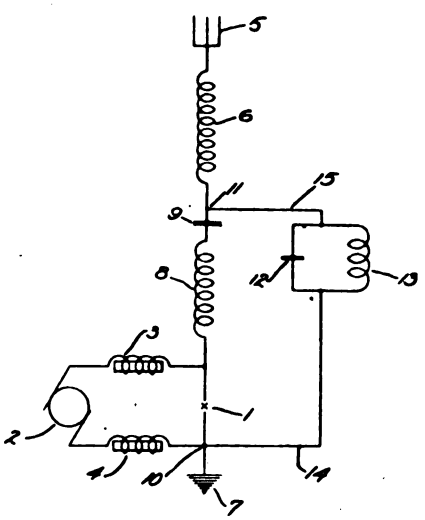
Method of constructing condenser to allow continuous variation and also to allow the use of gas or compressed air as a dielectric.

The above named and other objects are attained by employing improvements which comprise a set of stationary metal leaves or plates, and a set of adjacent turnably adjustable plates adapted to either partly or completely interleave therewith, casing means for enclosing said sets, means for mounting the parts, means for rotating the adjustable plates, and various other nover features, all as hereinafter fully described and specifically set forth in the annexed claims.

Radio Frequency Transmission System

No. 1,454,652: Patented May 8, 1923. Patentee: Haraden Pratt, San Francisco, Calif.

MY invention relates to a radio frequency transmission system, and more particularly to a system embodying a source of high frequency oscillations, such as a Poulsen arc, which may under certain conditions produce objectionable higher harmonic oscillations. These higher harmonics not only produce an energy loss, but they also present a problem of interference with stations tuned near the



Method of suppressing harmonics in arc or long wave transmission.

frequencies of the higher harmonics. As the number of stations increase, this interference becomes more and more objectionable, and it becomes not only advantageous to suppress the higher harmonics, but almost imperative to do so. One of the objects of my invention is to make it possible to suppress substantially all of the higher harmonics by means of a simple and inexpensive arrangement.

Answers to Readers of Radio World

Is there any difference in the hooking up of the U. V. 201A tubes and the regular 200 or 201? Are these tubes any louder? Will I have to use any special type of transformer? I am using the Acme Audio and General now. Will they work with these tubes?—H. Smith, Oswego, N. Y.

No. You can use the same hook-up for these tubes as for any other three element tubes. They are improved tubes which have certain advantages over the regular U. V. They are slightly better amplifiers than detectors but can be used as both. You can use any type of transformer that you are at present using with the other tubes. The transformers you are now using will function with these new tubes.

* * *

Where can I obtain the circuit diagram of the Mawhinney circuit, described in RADIO WORLD*?—A. L. Feldman, Red Bay, Alabama.*

Write to A. S. Mawhinney, 801 Riverside Drive, New York City, and he will advise you as to the cost of the blueprints.

* * *

Advise me if the coil for the Reinartz circuit described in RADIO WORLD *for Jan. 13 will allow me to hear the new stations operating on waves up to 500 meters?—Walter W. Ott, 45 Elmwood Ave., Irvington, N. J.*

With proper manipulation of the controls of this set you should be enabled to take all waves up to 550 meters.

* * *

What is the receiving range of the combined transmitting and receiving set described in RADIO WORLD *for May 19 by Carl Masson? My antenna is 150 feet long and 50 feet high. Would this aerial be satisfactory for transmitting? Would a shorter aerial be better? Where would a key be inserted to enable me to send code? What would be my range with code? Will using a five watt transmitting tube increase the range of the set?—Jack Fry, 1080 Pearl Street, Denver, Colo.*

As we have stated many times before, it is impossible to even estimate the receiving range of any receiver. The only way in which you can determine that is to build the receiver and try it out. Your antenna is too long for transmitting—100 ft. is about the proper length. Insert your key in the grid circuit. You will have to do two things to accommodate this set to code work. Obtain a key which can be closed (an ordinary line telegraph key with closed circuit switch will do), and also provide some means of shortening the microphone. See answer to your first question. The use of a five watt power tube will increase the range of your transmitter and will allow you to use more B battery, which will make your set more powerful.

* * *

Please tell me where I can get something that will prevent interference between stations.—L. Fitch, Springville, Tenn.

The easiest and best manner to cut out interference between stations is known as a filter circuit. Numerous filters have been explained from time to time in RADIO WORLD. We refer you to RADIO WORLD for January 20, or April 21. A filter consists of a set inductance in parallel with a capacitance connected in the antenna circuit. This circuit is tuned to the interfering wave, and the receiver is tuned to the wave desired. A wave trap, or filter, will not allow you to eliminate interference if both stations are on the same wave. Only stations on other waves which interfere, due to being powerful, can be filtered.

* * *

I have built a reflex circuit and want to know if it is possible to add another step of audio-frequency to it. Is it good policy to wind the primary and secondary of a coupler with the same size wire?—Jos. L. Reisler, 7736 Phelps Ave., Detroit, Mich.

It is possible to do as you suggest but if you are going to use another tube why not make it additional radio and audio, and gain the advantage of two steps instead of one? This will only necessitate the use of an additional radio frequency transformer in connection with the audio transformer that you will have to use. Yes, it is good policy to wind both stator and rotor with the same size wire.

* * *

What is the wave length of the Stockelberg "Pup" set?—H. H. Courtwright, 4119½ Bryan Street, Dallas, Texas.

Because of the fact that honeycomb coils are used in this circuit the wave length of this set is anything from 200 to 20,000 meters, depending upon the honeycomb coil you use.

* * *

What is the address of R. W. E. Decker, who recently had an article in RADIO WORLD *on a C. W. Transmitter?—Rev. Fr. Romuald Fox, O.S.B., Immaculate Conception Church, Valley Falls, Kansas.*

Mr. Decker's address is 834 Riverside Drive, New York City.

* * *

I have constructed the Turnbull set described on page 5 of RADIO WORLD *for May 26 and followed your instructions as closely as possible but it does not work right. I can get local stations but no distance. I am using the best apparatus and all my connections are soldered, but the tube will not oscillate.—Dr. E. S. Mayhew, 8524 Quincy Street, Detroit, Mich.*

Examine your antenna and ground leads and wires. Then, if there is no bad connection, make sure of your connections on your variometer. If the ground-filament wire is not connected at the joining of the two windings of the variometer the circuit will not function properly, and this is probably your trouble. Go over your connections very carefully, as too much care cannot be taken in making right connections and the slightest mistake will cause you trouble.

* * *

In RADIO WORLD *for March 17 you describe a one-tube super loop receiver by W. S. Thompson. Can this set be used with a WD-11 tube? If not, what tube would you suggest?—H. L. Thomson, 1130 Fifteenth Street, Moline, Ill.*

It is not advisable to use this tube in the set you mention. The circuit calls for a hard tube and also needs a tube with a greater plate and grid surface than the WD-11 tube possesses. The U. V. 201A tube could be used for this purpose if you want one which does not necessitate a storage battery.

* * *

How should I count the turns for the tapping of the honeycomb coil for the Pup set, described by R. L. Dougherty in the May 5 issue of RADIO WORLD*?—R. K. Hiner, RFD 5, Box 75, Rogers, Ark.*

The tap should be taken off from the inside turns, counting in the direction in which the wire is run. As every turn in a honeycomb coil comes out as a loop, it is only necessary to begin at the end of the wire and count the loops around the inside circle as the wire is wound.

* * *

Will the set described by Arthur S. Gordon in RADIO WORLD *for April 14 work on a loop? If it will not, what is the next best thing to use it with? I cannot erect an outside antenna because of the landlord's objections. Will it work on a ground alone? Will it work on an antenna alone? How is the set operated?—T. F. Miller, 47 Hikes Street, rooklyn, N. Y.*

You can accommodate this apparatus to a loop. By the use of the apparatus shown in the circuit you mention an outside antenna is rendered unnecessary, although with the circuit you will have to use a ground. The circuit referred to will be found on page 5 of RADIO WORLD for March 17, 1923. The aritcle in question was written by Arthur G. Shirt and shows a method by which you can very easily accommodate your present set to a loop. A wire strung around a picture moulding will also serve as an antenna, although there is a chance that the metallic structure of the building will lessen your distance due to absorption. Any circuit can be used for local work up to a distance of five or 10 miles by simply using a ground, and this is especially true with single circuit receivers. The set should be operated in the following manner: The tubes should be lighted, after making sure of all your connections, and the taps on the primary of the variocoupler should be varied, at the same time loosening and tightening the coupling of the tickler. A high scream will be heard, which will vary from a very high pitch to low, and then as the tickler is moved, it will again rise from low to high. It is at the dead center of these two carriers that you will hear the voice or music. You will have to determine the point on the primary and the setting of the condenser for each wave length for yourself, as no set point can be given for any wave length. If, when the station is tuned in the voice is muffled and comes in thickly, that is an indication of too much A battery and the filament should be turned down slightly until the voice comes in clearly, and then the vernier of the rheostat brought in until the set is just beyond the point at which the tube will "spill." It is at this point that the set is working the best and the best reception will be had.

How It Sometimes Happens

THE young radio wizard of the family arrives home from business, parks his hat on the first convenient hook, dashes into the "radio room," puts on the phones and turns up the bulbs—but no juice! He fiddles around a few seconds, and then—a sudden inspiration—with rapidly beating heart and shaking hands he takes out a tube. Wow! Every one of them gone—done gone galley west—burnt out!

Silence! Then with trembling lips and rising temperature he yells: "Say, who was fooling around this set of mine? Who burnt out my tubes? Hey, ma! One of those kids was foolin' around in here after I told them to keep out and now my tubes are all gone. Gee, a fella can't keep anything around this old house with those doggone kids foolin' around."

"Now, son, I told Junior that he could listen in and he just played around in there a little while. Maybe they just went out of their own accord. Don't you dare touch him, or I'll tell pa to throw that noisy thing out!"

Seamen's Rights to Medical Radio Service

THE probability that some masters of sea-going vessels may not, as yet, heve been fully informed in regard to the right of members of their crews to medical service by radio while at sea and to treatment in U. S. Public Health Serice hospivtals on reaching port has caused Surgeon General H. S. Cumming to direct the preparation and sending of posters giving full information to all vessels of the American Merchant Marine.

Curiously enough, this medical service is really a sort of sudsidy to merchant ships and sailors. A century and a quarter ago, when Congress established the Public Health Service, under the title of the Marine Hospital Service, it directed it to render medical aid to every American seaman who applied for it; and that for this each seaman should pay 20 cents a month. This was in 1798. In 1870 the tax was doubled; but in 1888 it was abolished, and since then all such aid has been rendered free. Even the expense of calling the Service by radio from away out at sea is borne by the radio companies without expense to ship or sailor. The forthcoming poster announcement reads:

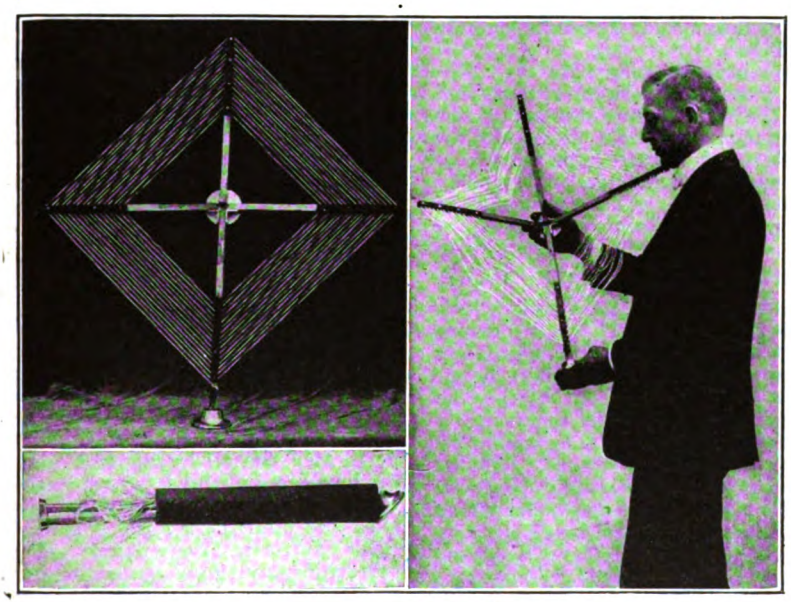
"The U. S. Public Health Service provides hospital care and outpatient treatment for sick and disabled seamen. Hospitals, specialists, dentists and other facilities are open to all persons employed on documented American vessels, and to the Coast Guard, lighthouse keepers, and certain others who help to keep the flag on the seas. An ambulance will go to the dock at any time upon telephonic call from a ship's officer.

"As you are proud of a good ship, take pride also in keeping your own body healthy. Most injuries are due to carelessness. Most diseases can be prevented. Prompt care of small injuries may save a limb. Early treatment for disease may save a life or prevent months of illness. Learn to keep well. Pamphlets on tuberculosis, venereal disease, and other common diseases are sent on request by the Surgeon-General, U. S. Public Health Service, Washington, D. C. A book, 'The Ship's Medicine Chest and First Aid at Sea,' will be sent on request to the master of the vessel. Any Marine Hospital will prescribe emergency treatment through radio shore stations."

A New Collapsible Loop Antenna

ALMOST practical, compact and easily portable loop antenna has been invented and patented by Mr. J. Nazeley, Palisade, N. J.

The "Portena" when extended has a measurement of 27 inches; but, by its ingenious folding design, it is inserted in a rigid tube 16½ inches long, the two ends of which are sealed by the center flange, and the case is ready to be shipped conveniently anywhere. The construction of the "Portena" is somewhat different from the loops now on the market. The four folding arms are made of maple, mahogany finish, ½ inch square, and hinged by rivets to channeled flanges on a central non-magnetic disc. Each arm carries two XX Bakelite strips, between which the turns of wire are held securely in slots. There are in all 16 turns of wire comprising the winding. The wire used is special and double insulated, and composed of 60 No. 38 copper and five No. 36 strands of phosphor bronze to obtain the maximum flexibility and to insure against stretching when often manipulated.



The "Portena" Collapsible Loop Antenna

The inventor of this portable loop, which he has named "Portena," for many years has done research work in the electrical and radio field. He is demonstrating that his loop, although it is only 15 turns of wire on four folding arms 13½ inches long, has successfully operated on receiving sets having two or more stages of radio-frequency for DX work or one stage of radio-frequency for local work.

In the illustration herewith the three positions of this new loop antenna can clearly be seen extended, folded and inserted in its carrying container.

Although this portable loop weighs less than 2½ pounds it is very rigid, being constructed to withstand abuses of the trail when carried to camps, automobiling, etc.

Why Magnavox *is* the Reproducer Supreme

OFFICIAL tests with the oscillograph prove that the Magnavox electro-dynamic receiver reproduces incoming wave forms with maximum accuracy.

The Magnavox can be used with any receiving set—the better the set, the more Magnavox can do for you.

When you purchase a Magnavox you possess an instrument of the very highest quality and efficiency.

R2 Magnavox Reproducer with 18-inch horn (as illustrated)

This instrument is intended for those who wish the utmost in amplifying power. It requires only .6 of an ampere for the field.

Price, $60.00

R3 Magnavox Reproducer with 14-inch horn

The ideal instrument for use in homes, offices, amateur stations, etc. Same in principle and construction as Type R2. Price, $35.00

Model C Magnavox Power Amplifier

For use with the Magnavox Reproducer and insures getting the largest possible power input.

2-stage, $55.00
3-stage, $75.00

Magnavox products can be had of good dealers everywhere.

The New Grebe CR-12 Receiver

IN the new Grebe receiver, the CR-12, is employed radio frequency and regeneration, the two factors most important in long distance reception. One of the distinctive features claimed by the manufacturers of this Grebe product, is the simple manner in which it may be used with any tubes now on the market. A 201A may be used in the radio frequency circuit and a WD-11 as a detector, a UV-199 in the first stage of audio-frequency amplification and a UV-200 in the second stage audio-frequency amplification. Such combinations may be used with either dry cells or a six volt storage battery. With no combination of tubes is more than one A battery necessary.

This receiver has but two tuning controls, one of which is calibrated to wave lengths, thus reducing to a minimum the elements of chance in tuning for a given station. With a wave length of 200 to 600 meters, the set will receive all wave lengths which have come into effect since May 15th. No outdoor antenna is used, in fact the antenna is supplied with the set, and consists of a silk covered wire 20 feet in length. This wire, although not unsightly, may be hidden back of a picture moulding or run along the base board.

Telephone jack and plug have been provided for those who wish to receive with telephone headset, and the insertion of the plug in the jack automatically disconnects the loud speaker and transfers the signals to the telephones. This new receiver is readily transportable, as it is, with the exception of the loud speaker, self-contained.

Compact Variable Grid Leak

A NEW type variable grid leak, which has been developed in the laboratory of the New York Coil Company after satisfactory tests, is now being manufactured in quantity for distribution. The attractive feature claimed by the company is that variation of any value from zero to 5 megohms can be secured without opening the circuit. This is possible through the arrangement of a roller which traverses a permanent resistance element. The instrument is compact and neat, and material and workmanship are consistent with the New York Coil quality. Literature describing the variable grid leak and other new products manufactured by the company will be mailed upon request by the New York Coil Company, 308 Pearl Street, New York City.

Coming Events

ANNUAL HOME AND CITY BEAUTIFUL EXPOSITION, featuring radio exhibits, Atlantic City, N. J., June 16 to September 8, 1923.

PACIFIC COAST ELECTRICAL ASSOCIATION, San Francisco, Calif., June 19-22, 1923; S. H. Taylor, secretary, 527 Rialto Building, San Francisco, Calif.

CANADIAN ELECTRICAL ASSOCIATION, Montreal, Canada, June 21-23, 1923; Louis Kon, secretary, 65 McGill College Avenue, Montreal, Canada.

A New Crystal Detector

A NEW crystal detector resembling a three element tube, made by the Burke Manufacturing Company, 94 Academy Street, Newark, N. J., should prove of great interest to owners of tube sets. The device resembles the new small 1½-volt tubes both in appearance and in the manner in which it is used. It is constructed to fit into the regulation six-volt socket and the crystal detector is sealed in the vacuum chamber of the tube. Inasmuch as crystal detectors need adjustment, provision has been made for the adjustment of this detector by lightly tapping on the side of the glass tube. This causes the catwhisker, which is a light spiral spring, to move over the surface of the crystal, and as a synthetic crystal is used which is equally sensitive over a large surface it is not hard to find a sensitive spot. The method of use of this detector is as follows: The regular detector tube is removed from the socket and the filament and battery removed and the leads shorted and grid leak short circuited, and the tube crystal is inserted in the regulation manner. Then the tube is lightly tapped and upon the turning of the controls the signals are heard.

This detector should fill a long felt want in the set of the amateur who wanted to use crystal detectors in his set for local work, but who did not feel like reconstructing his set to accommodate such a change. It is very neatly and carefully made and is an instrument that due to its particularly close resemblance to a tube detector, will not disfigure the best looking set, as no extra leads or unsightly wires are used for its connection.

A New Anti-Capacity Panel

THE Radio Panel & Parts Company claim excellent qualities for a new shielded anti-capacity panel for which they are distributors. This is a well finished hard rubber product shielded with perforated tin-foil by a patented process of manufacture and is so made that sections of the shielding may be lifted out with the point of a knife. It is claimed this anti-capacity panel eliminates screeching and howling due to body capacity. All standard sizes will be stocked and special sizes cut to order. Information may be obtained from Radio Panel & Parts Company, 70 Murray Street, New York City.

New Radio and Electric Firms

Nolte Mfg. Co., 61 Gautier Ave., Jersey City, N. J., to manufacture Reinartz coils.

T. R. Huber Electric Co., Rochester, N. Y., contracting, etc., $75,000; T. R. and E. A. Huber, A. B. Green. (Attorney, F. J. Mix, Rochester, N. Y.)

Syracuse Lighting Co., Syracuse, N. Y., has increased its capital stock from $6,000,000 to $20,000,000.

Combination Electric Switch Corp., New York City, $100,000; N. B. Gurock, C. Pincus. (Attorney, P. A. Zizelman, 42 Broadway.)

New DX Night Owl Records That Count

Fair to Middlin', Eh?

From Burdette M. Smith, R. L., Box 48, Le Mars, Ia.

I HAVE read a great number of the letters and records sent in to your DX Nite Owls Department and as mine is somewhat better than some I have seen and also not as good as some I have seen, I'll admit, nevertheless, I think it is a pretty fair one. Up to and including May 15th, I have heard one hundred eighty-eight (188) stations using phone. Of this number fifteen are amateur stations worked on or around 200 meters when they were using phone.

Following is the list of stations by states:

Alabama	1	New Mexico	2
Arizona	1	New York	7
Arkansas	2	N. Carolina	1
California	6	N. Dakota	1
Colorado	5	Ohio	7
Georgia	3	Oklahoma	6
Idaho	1	Oregon	1
Illinois	10	Pennsylvania	8
Indiana	2	S. Dakota	5
Iowa	13	Tennessee	4
Kansas	6	Texas	14
Kentucky	3	Utah	2
Louisiana	5	Virginia	1
Massachusetts	2	Washington	1
Michigan	3	Wisconsin	5
Minnesota	10	Wyoming	1
Missouri	8	Porto Rico	1
Montana	1	Canada	6
Nebraska	12	Cuba	2
New Jersey	3		

I wish to state here that this list of stations have been positively identified as to call letter and location before it was logged and this list has been recorded since November 1, 1922. All of these stations were received QSA on det. and one stage A. F. with the exception of WKAQ, San Juan, Porto Rico. I have heard twenty-seven stations over 1,000 miles away and every Class B station but one.

I wish also to submit the following list of stations received on Wednesday, April 18, from 8:15 P. M. to 11:45 P. M. All received on det. and 1 step:

WOC	—Davenport, Ia.
WAAW	—Omaha, Nebr.
WOI	—Ames, Ia.
WIAH	—Newton, Ia.
KYW	—Chicago, Ill.
WDAF	—Kansas City, Mo.
WHAS	—Louisville, Ky.
WEAB	—Ft.. Dodge, Ia.
WOS	—Jefferson City, Mo.
WHAD	—Milwaukee, Wisc.
KFDY	—Brookings, S. D.
WGV	—New Orleans, La.
KDKA	—E. Pittsburgh, Pa.
WLAG	—Minneapolis, Minn.
WEAH	—Wichita, Kansas.

THE editor of RADIO WORLD will be pleased to receive sketches of hook-ups drawn carefully in black ink or heavy pencil from the "DX Nite Owls" who send in records with a view to publishing them.

Send hook-ups of your sets, provided they contain something unusual. Send, also, the names of the various makes of apparatus you are using.

Make your letters brief and informative. Write on one side of the paper only.

The letters and hook-ups will be published in the earliest possible numbers of RADIO WORLD.

WLW	—Cincinnati, Ohio.
KFDU	—Lincoln, Nebr.
WJZ	—Newark, N. J.
KDYS	—Great Falls, Mont.
WCAE	—Pittsburgh, Pa.
KSD	—St. Louis, Mo.
WBAP	—Ft. Worth, Texas.
CFCN	—Calgary, Canada.
5KW	—Tuinucu, Cuba.
KPO	—San Francisco, Cal.
CFCA	—Toronto, Canada.
WMC	—Memphis, Tenn.
CHBC	—Calgary, Canada.
KFAE	—Pullman, Wash.
WMAQ	—Chicago, Ill.
KHJ	—Los Angeles, Cal.
WSB	—Atlanta, Ga.
KFDB	—San Francisco, Cal.
KFFQ	—Colorado Springs, Colo.
KWH	—Los Angeles, Cal.
WRAL	—St. Croix Falls, Wisc.
WDAJ	—College Park, Ga.

I have a Grebe CR 9 and for concert work for the neighbors and the family, use a Magnavox 2 stage power amplifier and Magnavox loudspeaker. I obtain enough volume to entertain neighbors over a mile away on still evenings, using UV 201 A tubes in set and power amplifier with 113 volts on plates of tubes in power amplifier. I have a .005 mfd. condenser across the input terminals of my Magnavox which helps greatly to clear up reception when using extreme amplification.

I am going to sign off here and if anyone cares to write me concerning further information regarding my set and my equipment, I will be glad to answer their inquiry. I am building a three stage R. F. amp. and det. and expect to make some better records than these.

A Little More from N. S.

From A. D. Turnbull, 57 Union St., Sydney, Nova Scotia

With single circuit regenerative using one R215A dry cell tube I can hear whenever they are going CFCF, CKAC, WGI, WBZ, WNAC, WMAF, WGY, WHAZ, WOR, NAA, WEAF, WAAF, KYW, 1OAA, 1AA (Canadian), KDKA, WIP, WFI, WAO.

On several occasions, using one stage peanut tube, I've heard CJCI, WOC, WFAA, PWX, WSB, WHB, WLW, WBAP, WPA, WDT, WVP, KDOW, WDY and QXJ.

Not bad for away up here. With one stage on fair evenings WGY is heard 25 feet from phones. Home-made set. This R215A is a Canadian tube, Northern Electric, and takes 22½ on plate, 1½ on filament. Excellent for detector or radio frequency work and gives great audibility on low-frequency.

Nothing Like Trying—to Beat This

From Wilbur Craig, McLean, Illinois.

I GET the RADIO WORLD every week and I am interested in the DX Nite Owls' records. Some of the records are good, some aren't quite so good.

I have had a one tube three circuit set since September. I have heard 217 stations, the list only shows 210, but as there were seven that I wasn't sure of I did not send them in. The most stations I ever heard in one night was 39.

March 10th I received WJZ, PWX, CFCN, KHJ, KFI and KGW. Five stations, all over 1,000 miles distant. I have heard both coasts, Cuba and Canada all in one night quite often. I am not saying that there are not better one tube records but I am fully satisfied. I have a three wire aerial 45 feet long, 25 feet high and in among trees.

WHB, KFAF, WAAC, 9XZ, WPAD, WWJ, 2XI, WIAO, WGAX, WBT, WGM, KDKA, WNAL, WEAK, KNJ*, WCX, WAAK, WJAN, WEAF, WJAX, WCK, WBAE, WCAT, WOAA, WCAS, WSB, WBAP, WCAB, WAAP, KHJ*, WOC, WCAP, WGAF, WQAQ, WIAQ, WKY, WCAZ, WLAL, WCM, 9AMI, WLK, WDAF, WIAR, WCD, WEAO, WPA, WDAJ, WFAC, WWI, 5XJ, WRM, WEAB, WNAD, WOAN, WGR, WLW, WFAA, WKAK, WMH, WMC, WBL, WAAF, CJCG, WJAP, WIP, WGY, WFAP, CFCA, WGAZ, WFI, WOR, WHAS, WCAF, 5YU, CKCK*, WJZ, WMAQ, WBZ, WOAZ, WOI, WGF, WDAP, WKAL, 5YQ*, KOP, WOS, WDAC, WCAF, WEAH, 9ZV, WSY, WMAC, WHAM, PWX*, WGV, WHK, WFAB, WQAA, WKAA, WDAO, WMH, WFAV, XIAZ, WLAJ, WHAP, KSD, WNAV, 9CPM, WCAJ, WSA, WDZ, CFAC*, CHBC*, WFAT, WLAK, WCAL, 9YF, 9DIL, WJAZ, WLAZ, WOQ, WHAB, WAAL, 8XJ, WSAT, 9DWG, WJAL, WJD, WMC, WPAL, WPAC, WCAY, KFFQ, WRK, WQAL, WNAR, WGAS, WFAZ, 6KW*, 9CLS, WNAT, KGW*, WEAY, WJAF, KXY, WHA, 9XM, WJAD, WBAA, WJAJ, WRR, CFCN*, WHAD, WSAH, WPAH, WCAM, 9DXD, 4XJ, WAAX, 9AWK, WOAX, WGI, WWAY, WBAH, WJYT, WDS, WHAX, WOAW, WEB, 9AWA, WJAS, KFDV, 9CCV, WHAS, WMAV, WSAJ, WIAS, KFDL, KFCL*, WIAE, 9UH, 9AWJ, WOAL, WWAD, CKCZ, KWH*, CFCF, WTAW, WMAK, WOAI, WEV, KFEL, WLAC, WWB, WDAL, WMAY, WTAS, KFEP, WDAE, WPAL, CAY, WDAR, WQAV.

Pittsburgh Church Unveils Tablet Given by Radio Congregation

Episcopal Churches all over the country on June 3 made the announcement that a bronze tablet, probably the most unique in the world, contributed by and dedicated to the unseen radio congregation of Calvary Church, Pittsburgh, Pa., was unveiled during the church services that night.

The Rev. Edwin J. Van Etten, pastor of the church, who was the first minister in the world to have his services broadcast; Bishop Alexander Mann, of the Pittsburg Episcopal diocese; H. P. Davis, "father of radio broadcasting," representing Station KDKA, of the Westinghouse Electric & Manufacturing Company, which station first broadcast the church services; and other prominent Pittsburghers took part in the ceremony.

More than 4,700 people representing 40 states of the Union, five provinces of Canada, Cuba and Bermuda, London, England, even sailors from ships sailing the Atlantic Ocean contributed to the purchase of the tablet. The contributions came in every form of legal tender—silver dimes, stamps, nickles, pennies and checks. There were a surprising number of Canadian dimes. A worker in the Southern cotton mill sent Dr. Van Etten two cotton socks with a nickels, pennies and checks. There were on the Atlantic sent the minister 120 pennies he had won playing penny ante.

These contributions came as a result of Rev. Van Etten's idea that his radio congregation to which he had been preaching since January 2, 1921, might like to contribute to some sort of memorial. Accordingly, during the reading of his regular church announcements Dr. Van Etten addressed, directly, his unseen hearers and told them of a plan to have small contributions from such of them as might like to participate. The sum obtained from the contributions was to be used for a memorial dedicated to them.

Responses to this idea were almost instantaneous. An hour after the announcement was broadcast contributions were received.

RECHARGE YOUR OWN BATTERIES

WHY pay out good money constantly for recharging batteries when the Ohio Motor Generator will do it quickly at a slight expense. This inexpensive home charging outfit keeps your Radio in service all the time and pays for itself—by charging your neighbors' batteries. It is noiseless, gives no trouble, and will even recharge totally exhausted batteries quickly.
The set is made up of the celebrated Ohio A C motor and D C generator wound for 6-10 volts. The motor and generator have ball bearings and are of the highest grade construction. It has none of the troubles common to cheap charging sets and will last a lifetime. It will charge quickly any three cell automobile or Radio "A" battery. Furnished complete on a substantial base with ammeter and field rheostat to adjust the charging rate from one to twenty amperes. The motor is for 60 cycle, 110 volt service and is complete with ten foot cord and attachment plug ready for instant connection and operation. Full instructions provided.
Motor and generator can be specially wound to charge six cell batteries or other unusual conditions.
Price $38.50 f. o. b. Cleveland. Ship by Express C. O. D., weight sixty pounds. Send your order today and stop paying good money for recharging. Your money back quick if not satisfactory.
NOTE:—If your service is other than 60 cycle, 110 volt, ask for special price.

Treat Your Radio Phones As You Do Your Watch

ONE of the essential parts of a radiophone receiving outfit is a good pair of telephone receivers, or a 'double head-set,' as they are sometimes called," said an official of Station WOC, owned and operated by The Palmer School of Chiropractic, at Davenport, Iowa, when asked about the operation and care of the telephone receiver. He continued: "On account of their connection with the receiving outfit, receivers are naturally subject to more mechanical abuse than any other part of the set. They are passed, as a rule, from person to person during a concert and thrown carelessly on the table afterwards where the cord is usually a convenient length for them to be bumped off onto the floor.

"A telephone receiver, simple in construction as it may seem, is the result of a great deal of experimenting by manufacturers and designers of radio equipment. Each of the two receivers consists of a coil of very fine wire, a permanent magnet and a diaphragm, these parts being housed in the hard rubber case with remarkable care. The size of wire and number of turns in the coil, the thickness of the diaphragm and the magnet and the amount of residual magnetism in the pole pieces are all very delicate factors in the successful operation of a telephone receiver. These factors are carefully tested in the manufacture of these instruments and any tampering with their adjustments usually decreases their efficiency or renders them entirely useless.

"The action that takes place within a receiver is as follows: Feeble electric currents set up in the receiving instrument by incoming signals are passed through the coil of a telephone receiver. This current is rapidly changing in value or fluctuating, which change causes a corresponding change in the degree of magnetism within the pole pieces. The diaphragm being suspended within this rapidly changing magnetic field, records these fluctuations in the form of mechanical vibration, which in turn is reflected to the ear in the form of sound waves. When this delicate function is kept in mind it is easy to understand why more than the average care should be taken in handling these instruments.

"It is well to observe the following rules regarding their use:

"Don't drop the receivers or subject them to a heavy jar in any way. A jar is a very effective means of demagnetizing a permanent magnet.

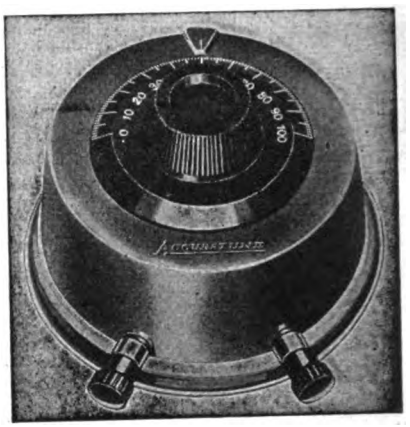
"Don't try to use an ordinary receiver, such as used on your office phone, to receive radio signals. While the principle of operation is the same in both, the receivers designed for radio are many times more delicate and time spent with the former is usually time wasted.

"Never remove the cap from the receivers or look for suspected trouble inside; such cases are very rare, and should they exist, it is not at all likely that you could locate or repair such trouble satisfactorily.

"Do not press upon the metal which you see through the hole in the cap. This diaphragm is made of very thin metal and must be in a perfect plane to vibrate as intended. The slightest dent or bend will ruin a diaphragm.

"It is well to have a convenient hook on which to hang the receivers by the head band when they are not in use. In short, apply the same rules to handling your phones as you do to your watch and they will serve you with equal faithfulness."

AUXILIARY TUNER



Helps Cut Out Those Interfering Stations

Not a mere wave-trap, but a high-grade tuner which when connected in series with antenna will materially improve the selectivity of the average receiver.

Na-ald Special Socket No. 499

It's the contact that counts

The Na-ald Special Socket No. 499 is a sturdy little socket with a dependable contact for the G. E. No. 199 dry-cell tube. It has special slot construction, and is moulded of genuine Bakelite. The heat from soldering connections will not affect Na-ald sockets.

Price 50 cents

The dual-wipe contact stripe of the Na-ald De Luxe socket avoid the trouble experienced with the socket of conventional design. Because of thorough cure and high dielectric properties Na-ald sockets keep plate to grid losses at a minimum (of particular importance in Flewelling Circuit or in Radio Frequency).

Price 75 cents

Na-ald Adapter for No. 199 tube, $1.00

Booklet with diagram of Hazeltine's Neutrodyne Circuit and other selected circuits packed with each Na-ald product or sent in exchange for cover taken from any Na-ald carton.

IMPORTANT NOTICE

While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

A New Radio Handbook

RADIO will have an important place in the International Aero Exhibition art, by International Correspondence Schools, Scranton, Pa., 564 pp., pocket size, many illustrations, diagrams, tables and data. Price $1.00, postpaid.

This is the latest in the popular handbook series published by the International Correspondence Schools. It was compiled by Harry F. Dart and technically edited by Francis H. Doane, principal of the School of Electrical Engineering. The subject matter is comprehensive, well arranged and efficiently condensed. The book should be of value to all radio amateurs as well as to those professionally engaged in the art.

Radio Section at Gothenburg Fair

RADIO will have an important place in the International Aero Exhibition at Gothenburg, Sweden, during July and August, according to dispatches from Consul Sholes to the Department of Commerce. A special radio section is under preparation, and several foreign and American firms are expected to exhibit apparatus, especially radio sets suitable for interplane and plane to ground communication.

A feature of unusual interest will be the daily receipt of news by radio from the United States for the American visitors at the exposition. Through the co-operation of a Swedish-American News Association and the Naval Communication Service, NAA will broadcast daily five hundred

RADIO WORLD'S QUICK-ACTION CLASSIFIED ADS

This department is intended for everybody who wants quick action on short announcements covering the buying, selling, exchanging or general merchandising in the radio field. Readers of RADIO WORLD will find that it pays to read these columns every week. Advertisers will get a ten-day service here—that is, copy received for this department will appear in RADIO WORLD on the news-stands ten days after copy reaches us.

The rate for this RADIO WORLD QUICK-ACTION CLASSIFIED AD. DEPT. is 5c. per word (minimum of 10 words, including address), 10% discount for 4 consecutive insertions, 15% for 13 consecutive insertions (3 months). Changes will be made in standing classified ads. if copy is received at this office ten days before publication. RADIO WORLD CO., 1493 Broadway, N. Y. C. (Phone, Bryant 4796).

SUPER-SIMPLICITY CIRCUIT—1,000 to 1,500 miles on one tube, one control, 150 to 25,000 meters. No rheostat, storage battery, vario coupler, variometer, 3-coil mounting, variable inductance, taps or radio frequency. Nothing to guess about. Complete hook-up and particulars, $1.00. No checks. Build your own. Save 50% and get better results. RADIO EXPERIMENTAL LABORATORY, Box 194A, Berkeley, Calif.

ARE YOU IN THE RADIO BUSINESS? If so, drop us a card for price list. If not, let us start you in a good paying business. We furnish everything and have a proposition that meets the needs of 99% of the public. Liberal discounts to agents. Immediate delivery. Write today. THE WILKENDA COMPANY, 500 Fifth Avenue, New York.

RADIO MANUFACTURERS—South America is the coming field. Have your catalogs, booklets and bulletins translated into Spanish by a specialist. Submit English originals for estimate. TECHNICAL, Box 126, Trinity Station, New York City.

Build your sets with quality parts and get sure results. Radio Parts Co., Box 56, Dunellen, N. J.

CASH FOR OLD GOLD, Platinum, Silver, Diamonds, Liberty Bonds, War, Thrift, Unused Postage Stamps, False Teeth, Magneto Points, Jobs, Any Valuables. Mail in today. Cash sent, return mail. Goods returned in ten days if you're not satisfied. OHIO SMELTING CO., 337 Hippodrome Bldg., Cleveland, Ohio.

WOULD YOU LIKE TO RECEIVE RADIO LITERATURE? Are you in the market for radio goods of any kind, either as a consumer, a distributor or a retailer? If so, send us your name and address on a post card and we will see that your name reaches the right people so that you will receive pamphlets, circulars, etc., regarding the goods you want. Address SERVICE EDITOR, RADIO WORLD, 1493 Broadway, New York City.

CRAM'S RADIO BROADCASTING MAP of the UNITED STATES AND CANADA. Scale 100 miles to the inch. In two colors, size 34x28. Printed on high-grade map paper, up-to-the-minute information, indicating all amateur and standard broadcasting stations, with complete index to stations. 35c postpaid. The Columbia Print, 1493 Broadway, New York City.

ATTENTION! Is your set equipped with that new discovery, The Desert Cactus Cat Whisker? The Whisker that brings in the long distance. If not, order today—Set of two for 25 cents and get details on that new (Mars) long range crystal receiver—Address, Mars, Box 822, Needles, Calif.

CHEAPEST TO BUILD—Easiest to tune. Get particulars Rokay Single Control Hook-up. Describe your set. Rokay Electric Company, Ingomar, Ohio.

A WONDERFUL CRYSTAL SET. Can hear all over Philadelphia, and sometimes outside of Philadelphia. Price with phones, $12.00; without phones, $6.00. Receiving sets, $35 to $200. Guaranteed or money back. Send Money Order or call. Williams Radio, 2339 N. 8th St., Philadelphia, Pa.

OLD MONEY WANTED—$2.00 to $500.00 EACH paid for hundreds of Old and Odd Coins. Keep all old money. Send 10 cents for New Illustrated Coin Value Book, 4x6. You may have valuable coins. Get posted. We pay CASH. CLARKE COIN COMPANY, Ave. 83, Le Roy, N. Y.

WIRING A HOUSE. By Herbert Pratt. Shows a house already built; tells just how to start about wiring it; where to begin; what wire to use; how to run it according to insurance rules; in fact, just the information you need. Directions apply equally to a shop. Sixth edition. COLUMBIA PRINT, 1493 Broadway, N. Y. C. Price, 35 cents.

FREE CATALOGUE. Ebonite panels, 7x12, 50c.; 23 plate variable condensers, $1.25; American No. 200 Tubes, $3.00; Amplifying, $3.75; W. D. 12 Peanut, $5.75; Sockets, 25c. Stewart's Radio Supply Co., 3124 Cherokee St., St. Louis, Mo.

PATENTS—SEND DRAWING OR MODEL FOR EXAMINATION AND OPINION. Booklet free. Watson E. Coleman, Patent Lawyer, 624 F Street, Washington, D. C.

EXCHANGE JOLLY, INTERESTING LETTERS through our club. Stamp appreciated. Betty Lee, Inc., 4254 Broadway, New York City

RECHARGE dry cell batteries. Cost, 5c. Instructions, 15c. J. Brent, 3 Stueben St., Bridgeport, Conn.

WANTED—Omnigraph in good working condition. Box 435, Hardin, Montana.

DO YOU WANT TO SAVE MONEY in making your set? Send for the Jan. 27 issue of RADIO WORLD, containing a full-page drawing of how to make filament control rheostats, as well as an easily understandable text, which makes the construction easy. 15c a copy, or start your subscription with this issue. RADIO WORLD, 1493 Broadway, New York.

SAXOPHONE, brass Alto, made by Buffet, Paris, with leather case cost hundred dollars new, both in good condition, WILL TRADE for complete WD-11 or WD12 three-tube receiving set or parts for same. Give names and value of parts. C. Dillman, No. 246, Webb City, Okla.

THREE NEW 50 WATT TUBES. Never used. $20 each. W. N. A. B., Bowling Green, Ky.

FOR SALE—Radio Receiver, Navy type, cost $595. Good condition. Dealers invited to call and see. Also 8 genuine "Vario-perm" guaranteed .001 variable condensers. Columbia Print, 1493 Broadway, Room 326, New York City.

TUBE RADIO SETS, $21.50 up. Parts sold at reasonable prices. Price list free. State whether interested in sets, part. McLean, 8103 Maryland Avenue, Cleveland, Ohio.

MAGNAVOX TYPE R3. Latest nationally advertised models, in original sealed factory cartons. List $35. Special introductory offer $25. Radio Central, Dept. W, Abilene, Kansas.

EXCHANGE LETTERS with friends everywhere. Pleasant pastime. Information for stamp. Smith, Box 3125, M. Portland, Ore.

FOR SALE—Unwired 3 stage radio 2 audio receiver. Write for information. Andrew Timberlake, Hinton, W. Va.

RADIO FANS! HAVE INVENTED STORAGE BATTERY CHARGER THAT OPERATES WITHOUT ANY COST FOR ELECTRICAL CURRENT. SEND FOR INFORMATION. R. H. McCONNELL, RAVENNA, NEBR.

FIXED COUPLER

A NEW IDEA IN TUNING CIRCUITS. Your construction troubles eradicated. C. O. D. $4.00 and postage. Satisfaction guaranteed. All bakelite. This new device eliminates vario-coupler, with switches, points and dials. Tune 175 to 700 meters. Descriptive outline and hookups Free. E. WATERMAN, 192 Ainslie Street, Brooklyn, N. Y.

MAGNAVOX TYPE R3.—Latest curvex, improved acoustic models, in original sealed factory cartons. List $35. Introductory offer $25. RADIO CENTRAL, Dept. W, Abilene, Kans.

SALE—Exide 120 hr. Battery, $12.50; Kellogg Sockets, 30c.; Transformers, $1.90. All kinds. Guaranteed apparatus at proportionate prices. KENNETH JONES, London Mills, Ill.

RADIO DEALERS ! ! !

Have you seen the list of Camps and Camp Directors which started in the MAY 12 issue of RADIO WORLD? Here is a list of all the Camps and Directors of camps in the United States, and is of essential value to any Radio Merchant who is anxious to enlarge his summer business. Get these people interested in installing radio sets in their camps for the benefit of the campers. Any single copy, 15c; or the four issues for 60c. RADIO WORLD, 1493 Broadway, New York City.

VENTRILOQUISM taught almost anyone at home. Small cost. Send 2c. stamp today for particulars and proof. Geo. W. Smith, Room M-643, 125 N. Jefferson Ave., Peoria, Ill.

HYPNOTISM—Controls self and others. Wants gratified. Ten easy methods, $1.10. "MIND-READING" (any distance)—Wonderful, $1.10. SCIENCE INSTITUTE, RW 1014 Belmont, Chicago.

$133 WESTINGHOUSE AERIOLA SR. with two stage amplifier complete with tubes and Brandes head set. $98. $125 Amrad No. 3500 four-tube receiver for $98. The Radio Shop, Virginia, Minn.

BUILDERS AND EXPERIMENTERS. Do you know that the Reflex circuit is one of the most interesting circuits to construct? You cannot guess how much fun you are missing if you fail to try out at least one of these circuits. See RADIO WORLD issues of Feb. 24 and March 3. They contain two fine articles by W. S. Thompson, with plenty of new Reflex circuits to experiment with. Don't miss these! 15c. a copy. RADIO WORLD, 1493 Broadway, New York City.

ELEMENTS OF RADIO TELEPHONY, by Wm. C. Ballard, Jr. A standard book on radio telephony, the work of a recognized authority. Accurate, simple, clear, reliable and strictly up-to-date. For the technical man who wants to post himself on radio and for the radio enthusiast who wants the fundamental principles of radio and their application tersely and entertainingly presented. Price, postpaid, $1.50. The Columbia Print, 1493 Broadway, New York.

ELEMENTS OF RADIO TELEPHONY

By WILLIAM C. BALLARD, JR.

Assistant Professor of Electrical Engineering, Cornell University

This is a standard book on radio telephony, the work of a recognized authority.

It is accurate, simple, clear, reliable and strictly up to date.

The man with a technical background who wants to post himself on radio will find this exactly the book for his purpose.

The radio enthusiast will find in it an excellent presentation of fundamental principles and their application.

SENT POSTPAID ON RECEIPT OF PRICE, $1.50, BY

Technical Radio Service Wants Latest News

Editor Radio World: The writer has established a service department in conjunction with one of the well established retailers in this vicinity. The purpose of this department is to be purely technical and to render service and information to the new fan and those floundering around in the dark wishing to obtain a good reliable set for themselves. Also for those who now have sets that sound wishy-washy or like a boiler factory in full bloom.

We have great difficulty here on the Coast to get the new improvements and the necessary information regarding new developments. From four to six weeks elapse between the time some authority in radio publishes his findings before we get a glimpse of it.

This is a deplorable condition and lies in the fact that no one has ever taken advantage of a service back in the East to hand out these findings hot off the griddle.

It is with the hope in mind that you can place me in touch with such a service and also place me on everybody's mailing list.

Yours very truly,
WESTERN RADIO ENGINEERS.
Frank D. Andrews.
5937 Sunset Blvd., Hollywood, Calif.

Opera Festival Cancelled By Royalty Demands

The Information Bureau of Broadcast Central, Aeolian Hall, New York City, sends the following interesting communication to RADIO WORLD:

We regret exceedingly that plans to broadcast the Spring Festival of Italian Grand Opera which were recently announced through this bureau failed to materialize owing to restrictions placed on the use of the music which is copyrighted by the American Society of Authors, Composers and Publishers. Attempts to substitute other music free from such restrictions as well as efforts to persuade the society to grant temporary permission to use the copyrighted music were of no avail.

"Every precaution is taken at WJY and WJZ to eliminate last-minute cancellations on our programs but circumstances peculiar only to the case of the Italian Grand Opera feature which developed but a few hours before the performance prevented our recalling the press announcements."

All Dressed Up and a Real Place to Go!

Editor, Radio World:—I have just received back from the binder two copies of RADIO WORLD, volume 1, April 1921 to September 1922, handsomely bound in half morrocco, light red English buckram, handsomely gold stencilled on the back, with gilt tops.

And this is a valuable addition to my already large wireless and radio library.

I will continue to subscribe to two copies in the future.

I write you this letter to respectfully request that just as soon as you publish an index, or for any future volumes, to kindly send me two copies of the same.

Yours very truly,
New York City. P. C. KULLMAN.

"Leviathan's" Call Is WSN

WHEN the Shipping Board's giant Leviathan sails on her trial trip from Boston on June 19, she will keep in touch with the land radio stations by radio and will answer the call WSN. Radio Operators Jack Irwin and E. N. Pickerill will be in charge of the big

Marconi Acquires Radio Station at Vienna

THE Marconi Company has taken over the Austrian Government radio station at Laaerburg, just outside of Vienna. This has necessitated negotiations between that company and representatives of the Naval Communication Service regarding charges for traffic handled in the future for the Naval Communication Service. This station has formed since the War, a link in the Naval Communication Service in Europe from Paris to Constantinople. Messages are sent from Paris by telegraph via Coblenz to Vienna. Navy enlisted personnel in the telegraph office at Vienna receive these messages and transmit them by telegraph a short distance to the radio station at Laaerburg where Navy operators, utilizing the Vienna radio transmitter during certain hours of the day, transmit the messages to American vessels in the Mediterranean and at Constantinople. Service will continue as heretofore via the Austrian radio station, but a certain rate per word will be paid to the Marconi Company for despatches transmitted through the Vienna station.

Naval Airships to Have Radio Compasses

PLANS for equipping the two new Naval rigid airships with radio compasses so that they can navigate in darkness or in fog are under consideration. These are the great ZR ships now building. It is believed that the radio compass installations can be made satisfactorily, and that this feature will prove a valuable asset for the efficiency and safety of both personnel and material through assisting the accuracy of navigation. The location selected is adjacent to the observation platform located on top of the ship, well forward. A coil has been designed which will enable observations to be made on frequencies extending over a band of from, approximately, 600 to 16 kilocycles. If this installation is made satisfactorily, it will be the first time a radio compass has been successfully utilized upon a lighter-than-air craft.

American Radio Exports Increase

DURING the first three months of 1923, the value of exports of American-made radio and wireless apparatus exceeded a half million dollars. An increase of over $30,000 a month since the first of the year is shown by figures just issued by the Department of Commerce.

In January, these exports were valued at $141,577; in February the value increased to $173,909, and in March the figure was $213,094.

Of the March exports, $70,273 worth went to Quebec and Ontario, $37,030 was purchased in Cuba, and $25,068 worth was shipped to Mexico. The weight of the shipments was approximately 58 tons.

Will Hold Examination for Radio Gunner

IT is expected that the Bureau of Navigation of the Navy will hold an examination for Gunner (Radio) about the middle of August, 1923. The bureau will notify the service at large as soon as it is definitely settled. In all probability, requirements for this examination will be the same as those incorporated in the Bureau's Manual. This is a step in advance for radio in the Navy as the gunner is a warrant officer and stands

Keep Your Tail Up—Advertise!

IN season and out of season advertise; tell your merchandising story. Especially advertise out of season. People earn and spend just about the same amount of money for their pleasure and amusement winter and summer, and they spend it for the things that are advertised.

Overhead is continuous. No manufacturer of a standard brand of radio goods can afford to stop advertising during the summer and let his brand be forgotten. Does Victor Phonograph or Wrigley's Gum or any of the others that have made millions in advertising ever stop?

Here is what happened to a success when they stopped advertising. Cook's Flaked Rice was one of the first and best known breakfast foods—their factory was running in three eight-hour shifts to supply the demand. They stopped advertising and went entirely off the market.

Pearline was advertised for years in season and out of season and made millions for the manufacturers. Their advertising ceased. What has become of Pearline?

The Magnavox manufacturers are increasing their advertising this summer. Watch the results in comparison with the other loud speakers who curtail or stop their advertising during the dull season.

What does a radio dealer think of a manufacturer who loads him up with goods in the late spring and then stops advertising until Fall? Can a radio manufacturer afford to treat his trade this way? Is not continuous, year-round advertising absolutely necessary?

Good merchandising means continuous sales. Continuous sales are only obtained through continuous advertising plus customer sales effort.

To advertise a brand or trade name for six months, and then stop advertising and let the buying public forget you for the next six months is, to say the least, bad management.

Advertise now. The great creative sales power of advertising will overcome a dull period. That is what advertising is for, to stimulate and create business when business is sluggish or dull.

We have evidence to prove that RADIO WORLD, the national illustrated weekly, brings quicker, larger and more satisfactory sales results from both the consumer and dealer than can be obtained for the same amount of cost in any other radio publication. Let us show you the evidence.
RADIO WORLD, 1493 Broadway, New York.

Radio License Required in Czechoslovakia

THE manufacture, sale, storage and importation of radio telephone and telegraph equipment in Czechoslovakia is only permitted under license from the state, says Trade Commissioner H. L. Groves in a report to the Department of Commerce. The Ministry of Commerce in cooperation with the ministry of Posts and Telegraphs are authorized to grant licenses for this purpose. The Ministry of Posts and Telegraphs also supervises and controls the manufacture, sale and storage of radio equipment and cooperates with the Ministry of Commerce in the granting of licenses.

Up to the present time only one company, "Radioslavia," has obtained a license for the manufacture of radio equipment in Czechoslovakia. It has not yet started production. This company is understood to be affiliated or closely connected with the French Company "Societe Francaise Radioelectrique." A German company, "Gesellschaft fur Drahtlose Telegraphie, System Telefunken," is said to be promoting a company, but it has not yet been granted the necessary license.

The attitude of the Ministry of Posts and Telegraphs toward the granting of licenses to transmit as well as to receive radio messages is said to be favorable in the following instances:

(1) Technical High Schools, for scientific purposes.

(2) Industrial establishments which have obtained special licenses from the Ministry of Commerce to manufacture radio equipment.

(3) Ships and aircraft.

(4) Electric power stations, waterworks, and other establishments of public utility, under special conditions.

(5) Companies which have been authorized by the State to broadcast matter of general interest, such as news-statements, exchange reports, agricultural reports, concerts, lectures, etc.

Licenses for the operation of receiving sets only will be granted to institutions, companies and those regularly taking the report stransmitted either by the State Telegraph Office or by companies authorized by the state to transmit such messages.

RADIO BROADCASTING MAP

FOR the benefit of those interested in Radio and those who are becoming interested, Rand McNally & Company have prepared a publication containing a wealth of information of greatest value. It shows in the most comprehensive way, the location of the broadcasting stations, gives their classification, the call letters, wave lengths, ownership, etc., of each.

The Rand McNally Radio Map of United States is 28x20 inches in size. The locations of broadcasting stations are shown by distinctive symbols. The call letters of each station are given, also the wave lengths of each. The Radio Districts with numbers are shown in red and the Radio Relay Divisions are in blue. Time zones are included. Alphabetical lists of stations and alphabetical lists of call letters are in the margins. Convenient pocket form with cover.

Heard at the Radio Counter

Episode XV

GOOD day, sir, anything I can do for you?"

"Yes, I am after a little information and thought that maybe you could advise me. You see I am perfectly dumb at this radio thing and at the same time I am very anxious to learn what it is all about."

"It's a very interesting game, once it gets into your system. It is really surprising how quickly you understand it. However, just what is your problem? I will try to help you out."

"Well, you see I intend camping in the mountains this summer with the kiddies, and, of course, I would like to take a radio set along, but don't see how I can without loading up with a lot of extra trunks and apparatus. Can you suggest any way to do it?"

"Why, everybody is taking their radio with them this summer. It can be accomplished very easily. You can take a small loop set, or even a small one tube set, if you have any place to erect a small antenna. Will you step over here while I show you some of the apparatus?"

"I suppose that they are all what you call crystal sets, aren't they?"

"Why, no. You see since they have brought out the dry cell tube, there is no need for heavy storage batteries, and therefore the sets are perfectly portable. They can be carried any place you go without the necessity of even thinking about batteries. Of course the loop sets do not need even an aerial or ground and can be operated even in a boat or canoe."

"Well, that is real interesting. I am sorry but I have to hurry away, but if you are here this evening I shall be pleased to drop in and arrange things with you. Have you a card?"

"Certainly, here you are. We are open until 10:30. Good afternoon."

Admiral Ziegemeier's New Duty

REAR Admiral Henry J. Ziegemier, Director of Naval Communications and one of the foremost experts of the Navy, has been detailed to command the Norfolk Navy Yard. His successor as Director of Naval Communications has not been named, but it is stated that Commander D. C. Bingham, assistant director will be acting chief.

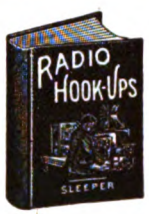
IF YOU ARE INTERESTED IN RADIO YOU NEED THESE BOOKS

Radio Books for Your Vacation

Telling How to Operate a Radio Set—How to Build a Set—Principles of Vacuum Tubes and Other Radio Problems



Radio Hook-Ups

By M. B. SLEEPER

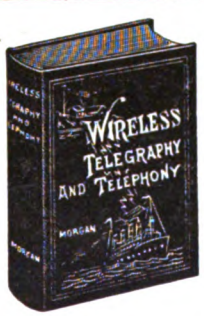
A book that gives you not only clear diagrams for all kinds of telephone and telegraph receiving and transmitting sets, but simple descriptions of each circuit shown and spaces for notes of results obtained.

PRICE 75c.

Construction of New Type Transatlantic Receiving Sets

By M. B. SLEEPER

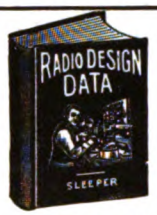
There is a peculiar fascination about receiving radio messages from the high-power stations of England, France, Germany, Russia and Italy, as well as those located in the Pacific Ocean and the Oriental countries. Several types of simple receiving sets for this purpose are described, with detectors and amplifiers to accompany them. Suggestions are also given for operating relays and reproducing the signals on a phonograph. Schedules of operating time for high-powered stations are given. In addition, there is some valuable data on home-made wavemeters for testing and experimenting .....**PRICE 75c.**



Wireless Telegraphy and Telephony Simply Explained

By ALFRED P. MORGAN

One of the most complete and comprehensive treatises on the subject ever published. A study of its pages will enable one to master all the details of the wireless transmission of messages. The author explains in simple language the theory and practice of wireless telegraphy and telephony. 154 pages, 156 engravings.....**PRICE $1.50**



Design Data for Radio Transmitters and Receivers

By M. B. SLEEPER

The only book that gives tables and data for designing, receiving and transmitting apparatus so that you need no knowledge of mathematics. It's the first book a beginner buys after he has learned the use of his phone receiver.....**PRICE 75c.**

Construction of Radiophone and Telegraph Receivers for Beginners

By M. B. SLEEPER

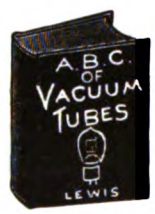
The man who wants to feel the real thrill of accomplishment, and who is not satisfied in the merely making use of what others have done for him, builds his own radio apparatus. Radio men can follow the data in "Radio Phone and Telegraph Receivers" with full confidence, because each piece of apparatus described was first made, tested and found efficient before the final design was accepted. Special receivers, both crystal and audion, are shown in detail. Regenerative circuits as well as audio and radio frequency amplifiers are described with clear photos, diagrams, and working drawings prepared especially for the novice and the man who wants to receive the radio telephone broadcast. A special feature is the phonograph type radio set and the loud speaker. Fully illustrated.....**PRICE 75c.**

The Radio Experimenter's Handbook

By M. B. SLEEPER

Throughout the preparation of this book, one purpose was kept in mind—Answer the Practical Questions of the "Novice," of the "Beginner," and the more advanced "Student." This book will help in the selection or construction of simple apparatus for the transmission and reception of radio telegraph and telephone signals. In the chapters on radio receivers the simplest crystal, the simple audion, and the regenerative types are described in quite some detail. The question of antennas, both for transmitting and receiving, are taken up. A good many helpful suggestions are given which will be of considerable aid to the experimenter. 16 chapters. Fully illustrated.

PRICE $1.00



The A B C of Vacuum Tubes Used in Radio Reception

By E. H. LEWIS

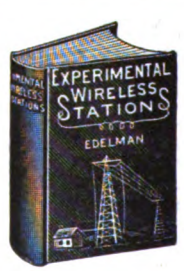
Assoc. I. R. E., and Radio Instructor

Written particularly for the person who "knows nothing about radio," but who would like to gain an understanding of the elementary principles of operation of vacuum tubes and various circuits in which they are used for the reception of radio-telegraph signals and radio-telephone music and speech. Illustrated.....**PRICE $1.00**

How to Make Commercial Type Radio Apparatus

By M. B. SLEEPER

This book describes in detail many commercial types of spark and vacuum tube telephone transmitting and telegraph and phone receiving equipment of all kinds. The experimenter will be able to get a world of ideas for the design and construction of his next piece of radio equipment from the very clear descriptions and the 98 clearly illustrated figures.....**PRICE 75c.**



Experimental Wireless Stations

By P. E. EDELMAN

Tells how to make apparatus to not only hear all telephoned and telegraphed radio messages, but also how to make simple equipment that works for transmission over reasonable long distances. Then there is a host of new information included. The first and only book to give you all the recent important radio improvements, some of which have never before been published. 392 pages, 167 illustrations.....**PRICE $3.00**

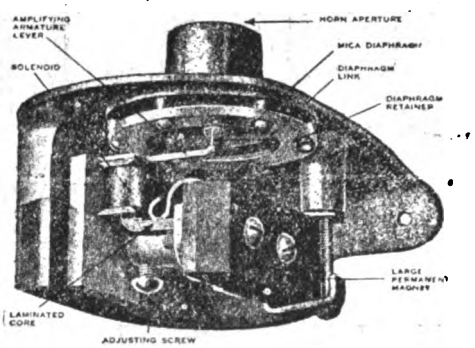
The Trinity Loud Speaker

The only device of its kind in the Radio field



TYPE "A1"
$25.00
21-in. Fiber Horn

Type "B" $12.50

Study the illustration carefully and you will understand why it produces full, clear, natural tones with perfect reproduction of all vocal and instrumental music. May be used with phonograph. No storage battery required.

The Trinity Loud Speaker is an instrument that combines the best qualities of a phonograph reproducer in combination with electro magnetic principles best fitted for radio amplification. Absolutely perfect reproduction of all music and speech without distortion. The volume may be regulated from that required for a room in your home to a tremendous output that can be heard hundreds of feet out of doors by simply increasing "B" battery voltage. No storage batteries required. The instrument is of a heavy duty type and is guaranteed fully by the manufacturers.

Ask your dealer for demonstration—if he cannot we can.

The Pezet One Tube Completely Portable Set Works Well Anywhere Without Aerial

(No Loops, No Plugs for Light Sockets, No Radio Frequency)

Read what the Radio papers say: Radio Globe of April 28, page 3, said: "RADIOIN MINIATURE. REMARKABLE RECEIVER. WORKS WITHOUT AERIAL." Radio World of June 16, page 9, said: "IT HAS BEEN DEMONSTRATED, AND EXCEPTIONALLY CLEAR RECEPTION RECORDED. . . . THROWING A WIRE TO THE WATER IN A LAKE OR CLIPPING IT TO THE FOLIAGE OF A TREE. EXCEPTIONAL SHARP TUNING, GREAT SELECTIVITY. . . . THE ESSENCE OF PORTABILITY."

This set has been praised by most of the radio papers. Come to my place and hear it. Complete instructions to make it cost $1.00. Cabinet and all parts (no phones, tube or dry cells) are $16.00. Federal phones, W.D. tube, A and B dry cells, $12.88. Get all that and make your set in a few hours, and then take it to your friend's house, or to the mountains, or up in an aeroplane, or down in a submarine. Demonstrate it anywhere and be always proud of it. It's small, neat and light. Carry it always with you.

THIS IS THE YEAR 1924 SET—GET AHEAD OF THE TIMES.

I AM READY TO SUPPLY YOU WITH INSTRUCTIONS AND ALL PARTS. IF YOU CANNOT CALL, SEND ME AN ORDER AND YOU WILL RECEIVE EVERYTHING BY PARCEL POST, C. O. D. (Detector tube at buyer's risk).

GOOD-BYE, LIGHTNING ARRESTER! **ADIEU, RADIO TROUBLES!**

C. A. PEZET, 46 West 65th Street, New York City
CALL EVENINGS.

Warning from Our Technical Editor

LETTERS galore have come to RADIO WORLD asking questions, making statements, and wild ones at that, regarding circuit diagrams published. Every one of them shows just one thing: Readers do not *read the instructions carefully.* They simply glance at the circuit, glance at the text matter, and then "fly off the handle."

This is especially true in the case of the more complex circuits, such as the multi-tube reflex circuits, and the super-regenerative, or other multi-tube circuits. All the letters show that the writer has not intelligently read the article, and therefore has misconstrued some detail or entirely missed the whole thing, with the result that he thinks he has a complaint to register.

If people who are going to construct sets only look at the diagrams without reading the text relative to it they cannot possibly meet with success. An architect can follow blue prints of a building if there are footnotes and measurements. Otherwise he will be just looking at a lot of white lines on a blue background. The same applies to radio sets. And also take into consideration the fact that the architect has studied his business and understands it.

If you have never made your own set before (and many letters state that, decidedly and disgustedly) don't pick out some multi-tube reflex, or super-heterodyne to start on. The instructions in the text and the diagrams are all thoroughly clear to one who has had a little experience, but you would not expect a man who has been fixing Fords to be able to fix his 17-jewel watch with a pair of gas pliers. This is exactly the status of the man who has never constructed a set when he tries to make his own super or reflex. And then, to back the bargain up, he never even makes a serious attempt to understand what he is doing, but glances at the instructions, and if he can't understand something he lets it go and starts in anyway.

In the construction of these complex sets there are many little details that have to be taken into consideration. They may appear minor at first glance, but when you think that even the *tiniest variation* from the standard will cause the circuit to be inoperative you will at least understand why it is so utterly impossible for you to do anything unless you *absolutely follow every instruction.*

Circuits have been worked out by experts, using apparatus that is capable of registering a micro-micro-ampere, and then when you go and disturb the balance of these fine adjustments by changing some minor looking connection, or connecting the wrong lead in some place, you should not expect results.

This article is not meant as a brake on the man who has a working knowledge of radio because he generally understands what he is attempting or at least has a definite reason for doing it, but when a man who has never made his own set tries to change the entire plan of things by working out some clever idea of his own, and then runs into trouble and blames the writer or the diagram, it is time to warn our readers to read the instructions *intelligently*, and follow them to the last inch.

In printing offices the rule is "Follow copy, even if it goes out the window!" That is a good rule in this case. If you follow directions absolutely and the set doesn't work then you have legitimate cause for complaint and criticism, and a real reason for asking questions.

VOLUME THREE OF

RADIO WORLD

[Entered as second-class matter, March 21, 1922, at the Post Office at New York, N. Y., under the Act of March 3, 1879]

A Weekly Journal, Published Every Wednesday and Dated Saturday, by Hennessy Radio Publications Corporation from Publication Office, 1493 Broadway, New York, N. Y. Telephone: Bryant 4796.

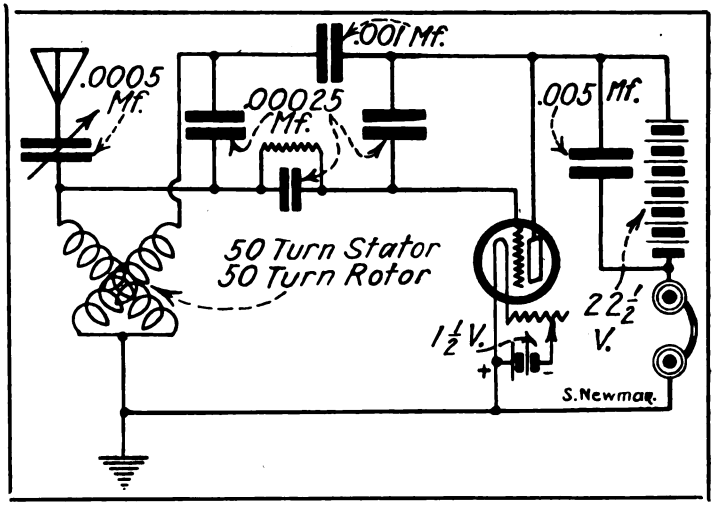
Vol. III, No. 13. Whole No. 65 June 23, 1923 15c. per copy, $6.00 a year

A Canadian "Hot Dog" Receiver

By A. D. Turnbull

ABOUT this time of year many experimenters and amateurs are trying to find some way in which to simplify their one tube sets so that they can conveniently pack them into suitcases and take them along "midst purling streams and woodland dells."

As the single circuit sets seem to have it over the tuned circuit sets in the matter of portability as well as volume, I have tried to devise some method whereby extreme selectivity as well as portability could be combined in the same set. The circuit shown herewith is about all that could be asked for in the way of a single tube regenerative set. A good point about this circuit is that there is only one control, the variometer, as once the antenna condenser is set, there is no more fooling around with it and all the tuning is done with the variometer. With this point in view, it is best to provide some means of vernier control, such as a small dial button for the variometer, as the tuning is extremely sharp, sometimes two stations coming in on one division, and a very slight turn of the variometer either way tuning one in to maximum and the other out.



Something new in "flivver" circuits. Extremely loud signals and sharp tuning are possible, but care should be taken in the construction of the condenser. The .001 condenser can be a variable if it is handy and will give better control of volume. The increase in signal strength will fully warrant the extra expense.

The apparatus needed for this set, exclusive of the panel and box, which I will leave for the builder to plan, as he knows his own needs best, and can get more fun out of it if he plans his own panel layout is: 1 variometer; 1 23 plate variable; 2 .00025 mfd. fixed condensers; 1 .00025 mfd. condenser and variable grid leak; 1 .001 mfd. fixed condenser; 1 .005 mfd. fixed condenser; 1 tube (dry cell preferable); 1 rheostat—10 ohm; 1 22½ volt B battery 1 1½ volt A battery.

In purchasing the apparatus, it is imperative that the condenser capacities be strictly adhered to as none others will give the proper results. It is also best to get mica insulated condensers as then you are always sure of the capacity being constant.

When assembling the apparatus it is well to keep in mind that the condensers and variometer should be thoroughly shielded and grounded to the ground post of the set.

The variometer being the main control of the set, it is best to buy a good standard make of about the same size shown on the diagram, preferably with about 50 turns on both the rotor and stator. If it is not possible to get one of the exact size, the standard make having 40 turns will do, the only difference being that the stations operating on 492 and 509 will not be heard as loud as with the larger size.

When tapping the variometer, make sure that you get the right side. There is generally one connection made on the shaft which serves as a connection to both the rotor and the stator. Make sure therefor when you are hooking your variometer in the circuit which connection is which, as if you reverse them, it will not help your set any.

Hooking up the condenser bank, around the grid leak and condenser, can easily be done by putting the three condensers in series, and taking your plate tap off the second one. This will eliminate wiring and make your connections easier and shorter. A word of caution in building this set is to make sure of your insulation. I found to my disappointment when out on a week end tramp, that it is not a good plan to use bare bus wire in connecting up your circuit. There is too much chance of a short circuit or connections crossing. I suggest that the set be wired with light cable such as is used in making drop lights, and running all the connections in bee lines.

A word as to the operation of the set. Make sure of your ground and throw a wire over a tree for an aerial. Then set your condenser at about 40 and turn your tube up. Turn your variometer slowly until you hear the carrier wave of the station, and tune in between the two squeals and listen to it pound in.

As a few closing words to the skeptics who desire to know just what this little circuit can do in the way of distance I might mention that 50 stations were logged in 24 hours, a few of which are WKAQ 3,000 miles, KFI 3,000 miles, WSB 2,200 miles. They were all copied using just one tube with 22½ volts on the plate.

If care is taken in the making this circuit will pleasantly surprise any one who constructs it.

Pitfalls of the Radio Investigator and Inventor

By Everett N. Curtis

[*Everett N. Curtis, the author of this article, is the lecturer on patent and trade-mark law at Columbia University and is a patent solicitor in active practice in New York City. He is the author of Curtis' "Manual of the Sherman Law" and a number of monographs. He was graduated from the Massachusetts Institute of Technology in* 1898 *and from the Boston University Law School in* 1900.—*Editor,* RADIO WORLD.]

MANY engaged in radio research and experimental work are the victims of their own lack of knowledge, or of inertia to take pains to acquaint themselves with well known principles underlying the patent law, are prone, when finding themselves in a situation in which their ignorance has led them, to blame the law or some person or persons whom they think have taken advantage of their necessities and caused them to lose valuable patent rights. The purpose of this article is to point out some of these pitfalls of the inventor for which he himself through ignorance is mainly to blame, and to indicate ways and means by which such errors may be avoided.

Generally speaking the inventor is woefully unaware of the importance of keeping records and drawings of his invention and preserving evidence of the earliest date thereof, the dates of disclosures to others, and the dates of reduction to practice. He is ignorant of the bearing which the prior art or prior knowledge and use or the two years statutory bar or abandonment of his invention has upon his rights before he applies for a patent. He is ignorant of the effect of many years of a concealed use of his invention such as for example, a secret process. He is ignorant of the effect of filing an application without a full disclosure of his invention, and without adequate claims covering the full scope of his invention. He is ignorant of the requirement that all applications for patent in this country must be filed by the inventor, and that the filing by joint inventors (so-called), is in many cases a snare and a delusion and likely to result in the patent being declared void. He is ignorant of the necessity of guarding against the disclosure to the world by the issuance of his patent in this country, until he has protected his rights by filing in foreign countries. He is ignorant of his rights where he makes an invention when employed by others, where such invention is in the same line of work as that of his employment. He is ignorant of the effect of licenses and assignments, and the duty imposed by law of recording assignments at the Patent Office at Washington. He is ignorant of the fact that in any event all he obtains from a patent is the right to exclude others from the patent domain and a right of recovery for his damages or the infringer's profits.

This enumeration may seem at first glance as embracing matters technical in character, and as only to be apprehended by a patent lawyer of mature judgment and experience. The fact is, however, that any person of average intelligence may with little application, sufficiently acquaint himself with the law as to safeguard his inventions to a considerable degree and very likely avoid long and vexatious litigation which might otherwise result.

The patent law in this country is derived from the English law as it existed at the time of the colonies. Under our constitution it is provided that the Congress shall have power to promote the progress of science and useful arts by securing for limited times to inventors the exclusive right to their discoveries. The word "discoveries" is unfortunate, but is interpreted by the courts to mean the same thing as inventions. Beginning in 1790, a number of patent acts have been passed by Congress, and the law has become finally crystallized in the Acts of 1870 and 1875 as amended to date.

The most important provision of the law is Section 4886, under which it is provided, among other matters, that any person who has invented any new useful art, machine, manufacture, or composition of matter, or improvement thereon, not known or used by others in this country before his invention or discovery thereof, may obtain a patent. Thus it is provided that in every application for patent there must be present invention, or exercise of the creative faculty; there must be present novelty or newness, and there must be present utility, or usefulness. It is also provided in effect in the same section that a publication, either here or abroad, two years prior to the filing of the application or a two years' public use or sale in this country prior to the filing of the application will preclude the issuance of the patent thereon. Accordingly underlying the validity of any patent, are the prerequisites of invention, novelty and utility and the so-called statutory bars. Even though the patent be issued, no defendant is foreclosed from showing such patent is defective in any one or more of their particulars and accordingly void.

All that the inventor secures by his patent is the right, in the first instance, to exclude all persons from making, using or selling the inventions covered by it. This, it is true, is a very substantial right and includes not only the right to an injunction but also the right to damages and profits. It should be borne in mind, however, that this right is negative in character and is only presumptive, and that a patent may be declared null and void by the courts for a variety of reasons, as for example, that the inventor was not the true inventor, that the so-called invention is not an invention but involves only mechanical skill, that it is not new, or that it will not operate, etc.

All inventions must be regarded in the light of the prior state of the art, and measured by the advance which they have made. If they are basic in character and perform a function never before performed, they are termed "primary" or "pioneer" inventions, such as the Goodyear process for vulcanizing rubber, the Morse telegraph, or the Bell telephone, and are construed broadly. If they are improvements upon what has gone before, they are secondary inventions and are narrowly construed. Mere mechanical skill is not invention, neither is mere aggregation, nor double use of an old structure, nor duplication nor enlargement, nor mere change of form.

Want of novelty may be shown by prior publications or patents in any language or by any prior knowledge or use accessible to the public. Want of utility may be proved by showing that the so-called invention is inoperative, or that it is injurious to the morals, health or good order of society.

A Handy Tuning Unit for a Loop Set

By Kenneth Malcolm, A. I. R. E.

THOSE fans who have purchased or built loop sets for use during the summer, occasionally would like to reach out for greater distances or would like a greater volume than that afforded by the sets in question. The provision for a regular aerial and ground would make this entirely feasible, as very frequently there come times when the atmosphere is almost entirely free from hot weather annoyances. By means of this provision, a single set could meet almost all the varying conditions of weather, and hence could be used all the year round.

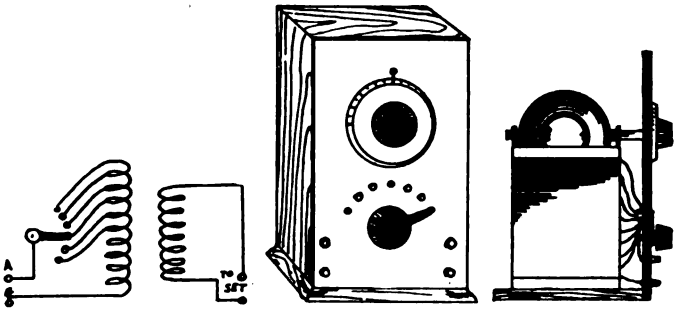
There are many sets that employ loops in which the change can be made directly, by simply removing the loop and connecting the leads directly to the aerial and ground. But sets such as the one described by the writer in a recent issue of RADIO WORLD, or those of the plain regenerative type, having the loop connected in the place where the secondary of the variocoupler would ordinarily be connected, would require the addition of a variocoupler unit before an aerial and ground can be used satisfactorily. Such a unit will be described in the following paragraphs.

The list of required material includes an insulating panel about 5x7½ inches, a variocoupler, a dial for the coupling adjustment, a switch and the necessary switch points for the wave length adjustment of the coupler primary, the necessary connecting wire, four binding posts and a cabinet.

The panel should be laid out carefully and holes drilled for the coupling shaft, the switch and switch points and the binding posts. The layout suggested in the drawing is neat and attractive. For the sake of convenience it is a good idea to mount the coupler on a sub-base, instead of on the base of the cabinet, or else it could be mounted directly on the panel by means of two small brackets. Before you fasten it permanently it is best to solder the tap leads to the switch points. Now you can assemble the whole affair, and make the connections as shown in the circuit diagram. The end turn of the coupler should go to the lower left hand binding post, the switch lever should go to the upper left hand binding post and the two secondary leads should go to the two right binding posts. When this wiring is done the panel may be secured in the cabinet, and your unit is complete.

If the set that you wish to use the unit with is of the type before mentioned, it might be well, first of all, to replace the single circuit loop jack with a double circuit jack, and also to mount a pair of binding posts at the lower left hand corner so that they will be opposite to the right hand posts on the unit. Nothing but the jack wiring need be changed. Simply connect the two leads that went to the old jack to the outer prongs of the new jack—the contact prongs. Now, neatly run wires from the two inner prongs to the set of new binding posts. By connecting the two right hand posts of the unit to the two new posts of the old set, the arrangement is ready for operation. If you follow the instructions closely the changes that must be made will be found much simpler than they sound.

With the double circuit jack arrangement, the change between regular aerial and loop aerial is entirely automatic. The aerial and ground connections on the unit may be left on permanently, and either aerial may be used at a moment's notice by simply plugging in or taking out the loop from its jack. This convenience cannot be entirely appreciated until it is tried.



Circuit hook-up and constructional details of a handy loop unit.

Sets which do not have the jack can be used with the unit by removing the wires that lead to the loop and connecting them to the right hand binding posts of the unit.

(*Continued from preceding page*)

One of the first steps to be pursued by an inventor should be to ascertain whether or not his invention is new, that is if it has patentable novelty. If he is a skilled mechanic, or if he is engaged in a business which brings him into close contact with the art and the trade, he will probably know if there is any commercial device on the market which anticipates his invention. It is quite possible, however, that there may be somewhere in the world a prior printed publication accessible to the public showing and describing his device in some language which he has not seen. If there is any such publication, it is probable there is a copy of the same in the United States Patent Office or perhaps in some public library in any of the great cities. A search therefore at the Patent Office and through technical libraries accessible to the public would probably disclose the publication. In order, however, to be fairly certain there were no prior publications, a very thorough search would be required, which would be expensive and perhaps beyond the means of the ordinary inventor, who would have to be satisfied with his own investigation at the public library, where both scientific works and copies of domestic and foreign patents might be accessible, or he might have made for him the usual preliminary examination by some resident patent attorney at Washington, who for a small fee would make a cursory examination of the class of U. S. patents where the invention was likely to be found and would send copies of the nearest patents. Such preliminary examination is often of great advantage, since it will usually disclose any very close references, but the inventor must be cautioned from placing too much dependance upon it, as it is at best only a makeshift and cannot in the nature of things be exhaustive. Where the inventor is well acquainted with the art, he could very well in many cases dispense with such examination, and rely upon the Examiner after the case gets into the office to discover and cite such references if any. Even after the usual preliminary examination is made, it is quite likely that the Examiner will cite references not disclosed by it. Such preliminary examination is, however, a safeguard, and in case the inventor is ignorant of the prior art, it is to be recommended for what it is worth.

Amateurs Increase by 1334 in Five Months

LEST some fans believe that the reception of broadcasts is the only popular phase of the radio art, be it known that amateurs are still entering the game of "key pounding" at the rate of nearly three hundred a month. Since January 1 last, 1,334 amateur licenses have been granted by the Department of Commerce, and on June 5 there were 18,232 such stations in the United States.

The distribution of amateur stations by Districts as of June 5th, was as follows:

District	Headquarters	Total
1	Boston	2,490
2	New York	2,629
3	Baltimore	1,994
4	Norfolk	444
5	New Orleans	941
6	San Francisco	2,172
7	Seattle	901
8	Detroit	2,932
9	Chicago	3,729
Total		18,232

The above table does not include special amateurs, of which class there are 201, no new licenses having been issued recently. It has been decided by the Department that hereafter District Radio Supervisors will issue special amateur station licenses instead of the Washington office.

The waves assigned to special amateurs are between 150 and 220 meters for use in CW telegraph. Regular amateurs operate on 150 to 200 meters.

WWV Transmits More Standard Test Waves

IN an effort to permit radio operators and fans to check their wave meters and instruments on standard waves, the Bureau of Standards will transmit standard wave lengths, commencing at 10:55 p. m. each night, on July 17, August 15, September 13 and 28, and October 7.

On the last date WWV will enable amateurs to calibrate their receiving and transmitting sets, since the band covered will be from 222 to 150 meters, the signals being sent between 1:50 a. m. and 3:41 a. m. The schedule, which should be kept for future reference, follows:

Date	Frequency, K/c	Wave Length, Meters
July 17	425-1,500	705-200
Aug. 15	425-1,500	705-200
Sept. 13	425-1,500	705-200
Sept. 28	500-1,700	600-176
Oct. 7	1,350-2,000	222-150 (Amateurs)

In continuation of the established practice the Bureau will transmit the call signals "WWV" both in radio telegraph and telephone, each wave length occupying about nine minutes of time.

Loop Antennae Data for Any Wave Length

WHEN you discuss loop antenna with the fan of average knowledge, he will start to tell you that it is perfectly O. K. for broadcast work or amateur reception, but "What are you going to do if you want to receive the long wave transatlantic stations or ships or commercial?" Well, if you happen to be in on the know you will, of course, laugh at him, but if you are not you will swallow it whole, and thereby miss a lot of fun and good experiments by heeding him.

Did it ever occur to you that you could make a loop that would respond to any wave length you wanted? Well, with a little extra work and some knowledge of the correct condenser capacities, windings and sizes, you can make loop antennae that will take the place of any outdoor antenna and you don't have to be afraid that the landlord will object.

Just to show you what you can accomplish if you want to, take a peek at the table below and give some deep thought to it before you condemn the landlord for making you stay off the roof with your wires.

WAVE LENGTH OF A FOUR-FOOT LOOP WITH VARIOUS CAPACITIES ACROSS THE TERMINALS

No. turns in loop	Condenser capacity in Microfarads (across terminals) .00005	.0001	.0005	.001	.002	.003	No. turns per slot
1	....	65m	128m	178m	250m	310m	1
3	130m	155m	290m	400m	550m	675m	1
6	230m	280m	500m	710m	1,000m	1,200m	1
12	430m	490m	920m	1,250m	1,700m	2,050m	1
24	760m	880m	1,600m	2,100m	3,000m	3,600m	1
48	1,550m	1,775m	3,150m	4,300m	6,000m	7,000m	2
72	2,200m	2,650m	4,800m	6,400m	8,800m	11,000m	3
120	3,930m	4,500m	7,900m	10,000m	14,700m	17,700m	5
240	7,600m	9,000m	15,650m	20,500m	27,200m	32,900m	10

Note: The slots are calculated to be one-half inch apart, and deep enough to accommodate the number of turns necessary.

It can be seen from the above table that it is comparatively easy to cover any wave length from 65 meters up to 32,900 by the use of the correct amount of wire and capacity. In order to figure the amount of wire for such a loop, the following method should be pursued: Take the number of turns necessary and multiply it by 16, which is the square of four, each side of the loop being four feet. It seems incredible that stations 3,000 miles away using waves of 20,000 meters can be received on a four-foot loop, but the table above has been compiled from actual data and everything is worked out so that fans can go ahead and use it.

To Make Your Old Set New

You can increase the range of your receiver by the use of parallel condensers in your circuit.

You can use honeycomb coils to load up your circuits by inserting them in the proper circuit. This means only the breaking of two leads and the insertion of the coil and should be employed in any short wave set, as it allows any range to be reached. It is especially useful in single circuit sets.

You can remove the present inductance and use either bank-wound inductance or re-wind your present one to meet the longer waves.

Increase the length of your antenna to take in the new waves.

Naval Radio Personnel Receives Rigid Training

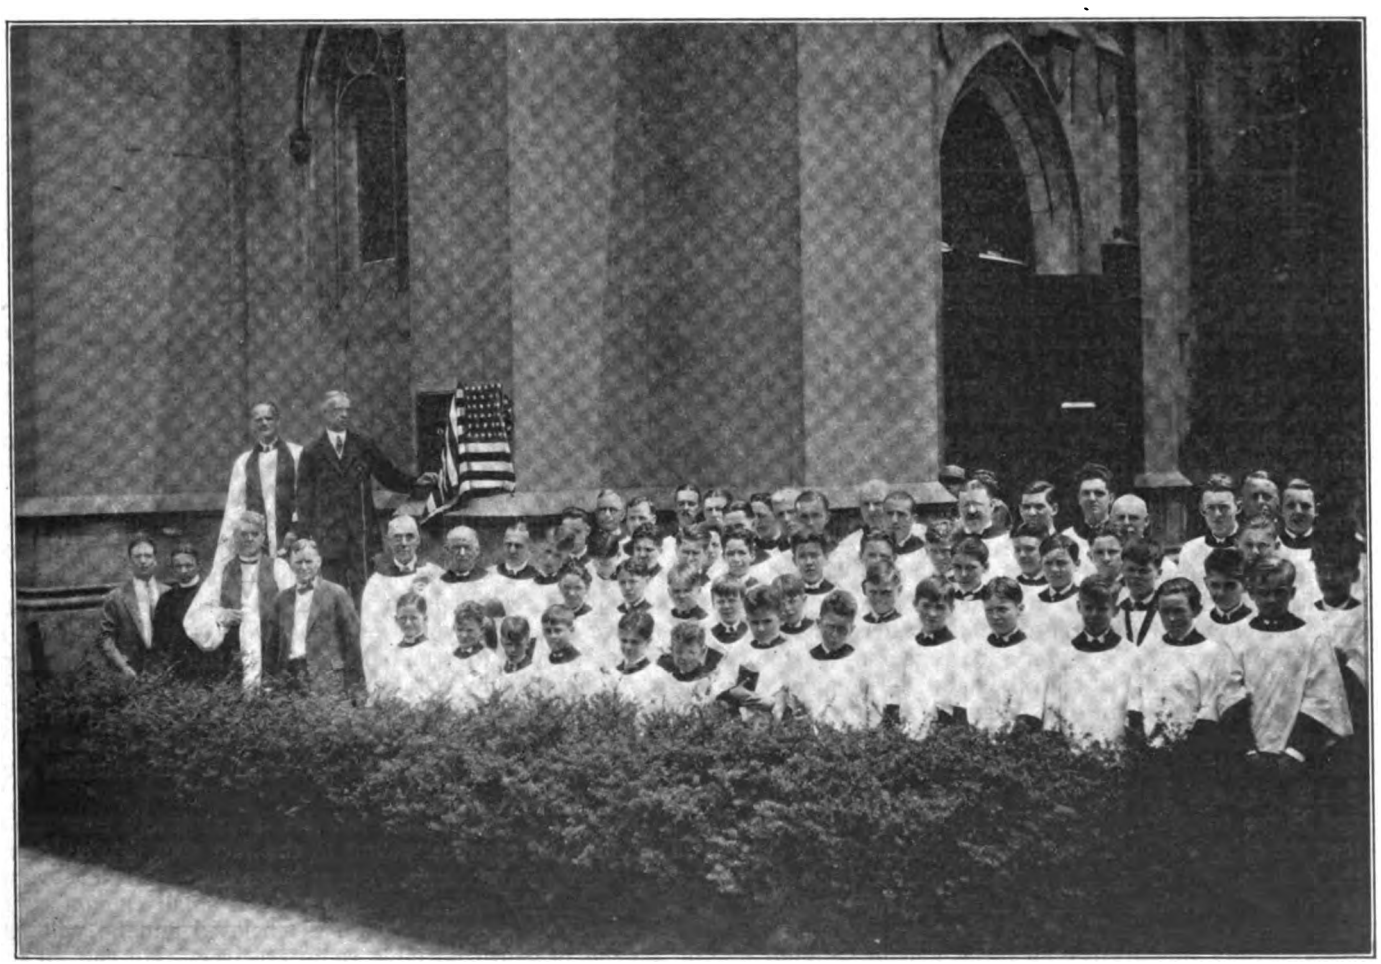
THE Naval Communication Service in the past three months has made gigantic strides in efficiency chiefly through educating its untrained personnel. Courses of radio instruction, in addition to the regular schools at Great Lakes, Norfolk and San Francisco, have been prepared and the results are "very gratifying," a recent report states. To-day the 1,200 radio men stationed ashore are receiving intensive training in fleet communication so that they will be familiar with sea operation. To-day the personnel of the Communication Service of the Navy is in better shape than in any other branch of the service, officers are credited with saying.

A survey of the radio personnel situation just completed by the Navy, shows that there are 2,443 radio men on duty, and that vacancies in the three higher rates exist. Following examinations held in May, 170 radio men were promoted to higher rates, fifteen of them becoming Chief Radiomen. There was still a shortage of 562 men in the service.

Opportunities in the Naval Radio Service are good for young men, communication experts point out, citing a recent case where a young man of 20, who held the rate of First Class Radioman, was persuaded to remain in the service, because at 32 he would be eligible for transfer to the Reserve with a regular income of $75 to $80 a month. No such opportunity awaited a young man in ordinary business pursuits, it was explained. This young man is now en route to sea duty in the Mediterranean.

Discrepancies in transmission of messages by the Navy have been decreased markedly during the past six months. During a recent period of supervision, five Atlantic stations had no errors, while the only two out of the other seven had over one-tenth of a word in a thousand wrong. Manipulation has improved greatly, operators are better instructed in procedure and are more attentive, the report states.

JANUARY 2, 1921
FROM CALVARY CHURCH
FOR THE FIRST TIME IN HISTORY
A CHURCH SERVICE WAS BROADCASTED BY RADIO WIRELESS
BY THE WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY
THIS TABLET WAS PLACED (1923) BY THE UNSEEN CONGREGATION



(C. Photonews)

Unveiling of the tablet dedicated to the radio congregation of Calvary Episcopal Church, Pittsburgh, Pa., first church to broadcast services. The story of this ceremony appeared in RADIO WORLD for June 16. H. P. Davis, of the Westinghouse Company, is shown unveiling the tablet.

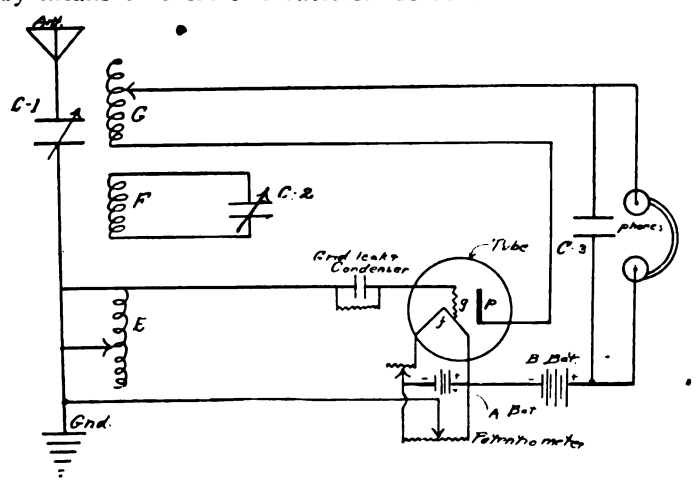
Tube Hook-Up of Interest to the Vacationist

By C. White, Consulting Engineer

THE advent of the WD-11, WD-12 and U.V.-199 now makes it possible for any one to own a radio set without feeling the burden of unnecessarily heavy upkeep expense. There are no battery chargers or bulky storage batteries to be contended with, and, above all, a portable radio set is within the reach of each and every vacationist. But it must be remembered that all of these tubes are not soft detector tubes and a set designed to use them properly must take this fact strictly into account. A soft or gaseous tube is very critical in the adjustment of its plate voltage and filament current while a hard, or high vacuum tube, when used as a detector is not appreciably sensitive with respect to either of these two controls. Therefore it is quite evident a receiver of the regenerative type that is built to function well with soft detector tubes might not give any reasonably good results with the new types of tubes unless certain changes are made. Hence since the new tubes are not very sensitive in regard to plate voltage and filament current it is foolish to expect any wonderful results if we attempt to control regeneration by means of these two factors. A better method of con-



Circuit incorporating a new idea in coupling. The three coils are wound on the same form and the feedback coupling between coils E and G is controlled by the condenser C2. Extreme selectivity and very fine control of the regeneration can be had by this means and it is absolutely quiet and stable in action, as well as free from interference.

trol is to look to the design of some type of tickler coupling which would offer a better method of vernier control than the rotating coil or rotor such as is commonly used on the single circuit type of regenerative receiver. In the type of circuit outlined in this article I have endeavored to overcome the difficulty of installing a mechanical vernier arrangement by using an electrical method instead of the movable or rotor tickler coil.

The coils E, F and G are wound side by side on the same bakelite tube, but the coupling between the tickler G and the tuning coil E is very loose as long as the circuit formed by the inductance coil F and the condenser C-2 is not tuned to the same wave length as the inductance E and the condenser C-1. Hence there will be practically no feed back action and regeneration can not be accomplished. But if F and C-2 are tuned to the same wave length as C-1 and E the coupling between E and G will be so increased that the tube will oscillate. Now by varying the setting of the condenser C-2 we can control the feed back or regenerative action with more ease than is possible with the ordinary style of rotor tickler. The construction of the coil units is quite simple since all three coils are wound side by side on the same tube, which should be four inches in diameter. The coils should be placed in the same relative positions as indicated by the schematic diagram: that is, the coils E and G should be on the ends of the tube while F should be in between the two. All the units are wound with No. 22 D. C. C. magnet wire. The coil E has 60 turns in all with taps at each 15; F has 40 turns with no taps, while G has 40 turns tapped every 10 for switch-points. There should be about one-quarter inch allowed between any two adjacent coils, and, figuring around 20 turns of wire to an inch, then about nine inches of tube length will be required. The condensers C-1 and C-2 are 23 plate air variables with some reliable type of vernier adjustment. The condenser C-3 is nothing more than a by-pass condenser for the phones and should have a capacity of .001 mfd.

The operation of this set is just about as simple as the construction. A little experience will be required at first in order to get on to the sensitivity of the various controls. In general there are two methods of tuning in a phone or broadcasting station. One is called the zero beat note method and the other is the critical point method. The former is accomplished by keeping the detector in the state of oscillation and moving C-1 and the taps on E until the carrier wave of the station is picked up. This fact is noted by a characteristic whistle, and as soon as we tune the wave the whistle will disappear for a point on our adjustment and then will reappear if we continue to move our condenser dial. The point where it disappears is called the zero beat note, and if we turn the condenser C-2 until the tube ceases to oscillate the station will be tuned in, and the amount of volume can be controlled to a certain extent by the condenser C-2 which will control the regeneration. This method of tuning in should *not be used* in cities or densely settled localities where there are other radio receivers nearby. It greatly disturbs the other fellow, not only annoying him but encouraging on the part of others the same method of tuning, which if carried out by many others would seriously impair reception in the neighborhood. In country or very thinly settled radio districts of a suburb this method can be used. But the best general method to use is the critical point method. In this the tube is set upon the point of oscillating by the adjustment of C-2. By a little experience you will soon recognize this condition by certain characteristic sounds in the phones. Now as C-1 is slightly moved a sort of breathing sound will be heard if a station is picked up and by finer tuning adjustment of the condenser it can be brought in clearer. C-2 must be moved along with C-1 if the latter is moved to any great extent. When the tube jumps into oscillation we can learn to recognize this conditon by a sudden click in the phones at the start of the oscillations and a sound similar to escaping steam or vapor that accompanies the state of oscillation. With a little precaution on your part you can readily learn to prevent this from occurring and save annoying your neighbor who is trying to get some pleasure out of radio likewise. After you have tuned in your station by this considerate and sportsmanlike method you can use the 300 ohm potentiometer as a vernier adjustment on the amount of regeneration and volume. With local stations too much regeneration will sacrifice quality for volume.

Let me repeat that this set is extremely economical to build and operate, owing to the fact that dry cells replace expensive and heavy storage batteries. The clever amateur can readily assemble this set in a small cabinet complete with "A" and "B" batteries enclosed and he will have a good practical portable radio receiver. He can take it on his motor trips, his camping trips and to his summer cottage. All that will be necessary is to set up a suitable aerial and he will be ready to operate.

How to Get Best Results from a One Tube Regenerative Set

By Byrt C. Caldwell

HOW many of us, when we look at those long lists of Radio Golf records made with one tube, sigh and wish that we could make those distance records too? Well, you can, and I am going to tell you how.

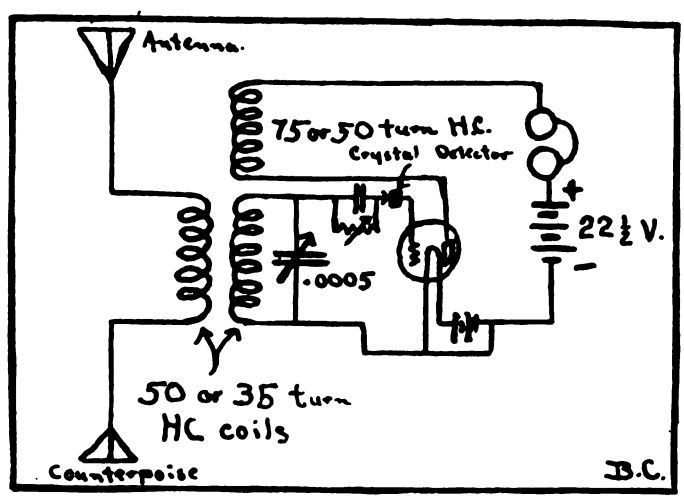
Without a doubt, the ideal one tube set for long distance work is the reflex. But as most of us have regenerative sets, I am going to write only about them. The best regenerative set is the three circuit, but wonderful results can be obtained with single circuit sets. If you have no set as yet, and are contemplating buying one, by all means get a three circuit set. The slightly increased cost will more than repay you by the better results and the greatly increased selectivity. The one I constructed and used was a honeycomb set, and I would advise anyone to use this kind. Some say that honeycombs are inefficient on low wave lengths but this is far from the case. I have obtained better results with mine than have many that I know of who are using sets which employ two variometers and a variocoupler.

I will start with the antenna and ground system. Without a good antenna and a good ground, DX results are impossible. A one wire aerial about 40 feet high and 80 feet long, constructed of braided wire if possible, is the ideal antenna. A buried copper or iron sheet ground is better than a water pipe ground. Some fans are prevented from obtaining good results because they live in a locality where it is an impossibility to get a good ground. For these, a counterpoise should be constructed. In fact, where it is possible every one should employ a counterpoise. This consists of another wire directly underneath the aerial wire and about ten feet from the ground. This is used in place of the ground. A counterpoise will give results two to ten times better than a ground. Have both antenna and counterpoise insulated as well as possible to prevent any losses of the tiny bit of energy which is collected. Use the best phones you can afford to buy.

We next come to the tuning. A little common sense, mixed with practice, will enable you easily to double or even to triple the range of your set. This is no exaggeration. When we look at the average broadcast fan and watch him twirl the dials, we wonder how he can get any results. In tuning three circuit sets, proceed as follows: First, after the batteries are connected and the filament is lit, place the secondary condenser at approximately the position for the wave length desired. Then tighten the coupling between secondary and tickler until the set howls. Then gradually loosen the coupling until this howling just stops. Now vary the secondary condenser until a station is heard. Many let the tuning go at this. However, the coupling between the primary and the secondary should now be varied. Do this carefully and slowly until a loud click is heard in the phones. Better results can be had if a condenser is put in parallel with the primary. When the rough adjustments above have been made, use infinite care in making much finer adjustments and you will find that you can bring in stations loud and clear that you never even heard before. Vernier attachments are extremely useful in making these fine adjustments and, for a nervous person, they are almost absolutely necessary.

Any fan who follows these directions carefully will find that, with a little practice, he will have doubled and tripled his range, and he will no longer look at the records made by the "DX Nite Owls" with a feeling of despair, for he will have become one of them himself.

I am showing here the hook-up of my set, which is one of the simplest and one of the most efficient possible to construct. You will notice that I use a variable grid leak. This greatly improves any set as you will find if you test one out. There are several good ones on the market. Connecting a crystal detector in the grid lead as shown will sometimes greatly increase the range. Don't be afraid to experiment with the connections of your set. You are liable to discover some little kink that will greatly increase your range. However, there is one precaution I would give before telling you to do this. Place a ballast tube in your "B" battery lead or use some other audion protective device, or you are liable to blow out a perfectly good audion.



Circuit diagram of a three unit regenerative set incorporating a new idea. A crystal detector in the grid circuit is said to increase the volume and also the range of the circuit. Try it out—it sure does "make 'em perk."

You will notice also that I do not use a rheostat. I have found it unnecessary for Myers, WD-11, and U. V. 201. I believe that they are unnecessary for any tube if the proper voltage A battery is used.

In a honeycomb set the proper coils for most stations are primary and secondary 50 turn, tickler, 75 turn. However, some of the stations with low wave lengths, such as WNAC (286 meters) require 35 turns for primary and secondary and 50 turns for the tickler, unless an antenna series condenser is used.

What is a "Converter"?

A converter is a machine used to convert D. C. to A. C. (direct current to alternating current). It is similar to a motor in construction, but is supplied with slip rings instead of a commutator.

RADIO PRIMER

For the New Army of Radio Beginners

By Lynn Brooks

TUNING REGENERATIVE CIRCUITS: As before stated, a regenerative circuit allows great amplification of signals if properly tuned. The basic principle of this was explained, and we shall now see how it should be tuned to get that amplification, as well as the extremely sharp tuning that is possible with such a circuit.

Referring to the circuit published on page 11 of the June 16 issue of RADIO WORLD, where the combination circuit was shown, it is called to your attention that there are two circuits possible with this hook-up. We are mainly concerned with the regenerative circuit, so will explain the tuning of that particular one.

When it is desired to use the set the tube is turned up about half way, first making sure that the batteries are connected in the proper manner. As the primary or antenna circuit is the controlling factor in the tuning this circuit will have to be tuned first. This is accomplished by setting the switch arm or slider at a point approximating the wave length of the signal desired. Then the inductance of the secondary is varied along with the coupling of the secondary circuit. When tuning this part of the circuit the condenser C2 is not varied until the entire circuit is tuned, and then it is brought into play to increase the selectivity or cut down interference. All this time the tickler is not brought into play, but after the secondary coupling is closed or tightened the tightening of the tickler should be commenced. As it is tightened a rushing sound will make itself heard in the phones, and suddenly a sharp click will be heard. If signals were heard before the click a noticeable fact will be that they will lose their tone and become mushy or wishy-washy after the click. This is an indication that the point of regeneration has passed and that the circuit is oscillating or forcing oscillations through the circuit. In this condition it acts as a small transmitter, and the coupling of the tickler should be loosened and then increased up to just the point where the signals are loudest without bringing the oscillations over, or making the tube "spill."

The secondary circuit is now tuned, and if the signals are not loud or there is interference the primary circuit should be re-tuned to the place where the signals are loudest. After that all signals for one wave length are tuned by means of the secondary inductance and condenser, secondary coupling and the tickler.

If care is not taken in the tuning of a regenerative circuit you will become the pest of the neighborhood, and every one owning sets capable of picking up undamped signals will be bothered with "birdies," which manifest themselves in squeals, howls and little, high-pitched notes, which vary with every change in the tuning of the set. A little care taken in the tuning of the set and signals will pound in, and the maximum of amplification due to regeneration can be accomplished, and at the same time the set will operate quietly. The signals, instead of suddenly jumping in from a forest of howls and squeals, will be tuned in gradually and smoothly and will be a revelation of smoothness and quality. This method of tuning also obviates the necessity of re-tuning a station upon hearing it. A few precautions and instructions upon this method of tuning are necessary.

When tuning in on a regenerative set do not turn up your tube brightly and tune by the "beat note" method. This is what caused the noise in your and other receivers. Turn your tube down to the point at which it just has a sort of breathing sound when the coupling of the tickler is closed or tightened. If this is done properly no carrier wave notes will be noticed. Then do not disturb it and when the signals are tuned in you will notice that the carrier waves of the stations are not present to cause distortion and noise, but the voice or music will come in clear and loud.

When using a regenerative set it is always best to include a variable grid leak in the circuit. This will remove the tendency to howl on the part of the set and will allow the maximum amplification when properly set for a tube.

Do not let your receiver oscillate. When the click is heard, do one of two things. Decrease your tickler coupling, or vary the secondary condenser until it is just below this point, and note the clarity and strength of the received signals.

It must be borne in mind that the regenerative circuit, unless handled by some one who is used to it, is a tricky circuit as far as selectivity is concerned and at certain times unless a complete knowledge of your set is in your possession it will seem impossible to separate one station from another, or else one station will come in so loud that it will render any signals of less intensity inaudible by drowning them out. This is generally the fault of the tuning of some particular part of the set, or else there is some part of the set that due to faulty wiring is so close to another integral part of the circuit that the transference of energy is taking place through that place instead of the tuning controls. If such is noticed the place to look for trouble is in your wiring. In wiring a set see that all the leads cross each other at right angles, and that they do not run parallel for too great a distance, and even then it is a good plan to have a fair amount of separation between them. A properly designed and operated regenerative set is very selective in tuning.

In no set, either regenerative or straight detector circuit, where a tube is used as a detector, should the filament be turned up any higher than is necessary to obtain signals of intensity enough to make themselves comfortably heard in the receivers. If the tube is turned up higher the tube will oscillate and the signals will be no louder. They will be distorted and the original quality of the voice or music or signals is lost due to that distortion. It is also a waste of both valuable filament life and current. The tube that operates longest is the one that has been used properly, and just because you can put all the current into a tube without burning it out is no indication or excuse for doing so.

It is better by far to have a crystal clear signal in a pair of phones than to have a room full of funny noises and distorted music in a loud speaker. The real radio man is always known by the manner in which he tunes his set.

DISADVANTAGES OF REGENERATION: Due to the fact that the common regenerative circuit has the power of oscillating (which same principle is used in transmitters) a regenerative circuit, unless properly handled, will generate power of its own, and re-radiate this power, making a small transmitter of itself, whose wave length changes with every change in the tuning of the receiver. This disadvantage is paramount in closely populated sections, where there are numbers of regenerative sets handled by people who do not understand that they are causing interference in neighboring receivers by their sets. A regenerative set if allowed to oscillate will cause interference in receivers over quite a distance, and the persons owning regenerative sets in the neighborhood will be bothered by the radiated wave of the first set. Bear in mind that a regenerative set always gives the loudest and clearest signals just below the oscillating point, or just below the point at which it perks up or "spills."

An Attractive Mounting for Tube Sockets

By Arthur G. Shirt

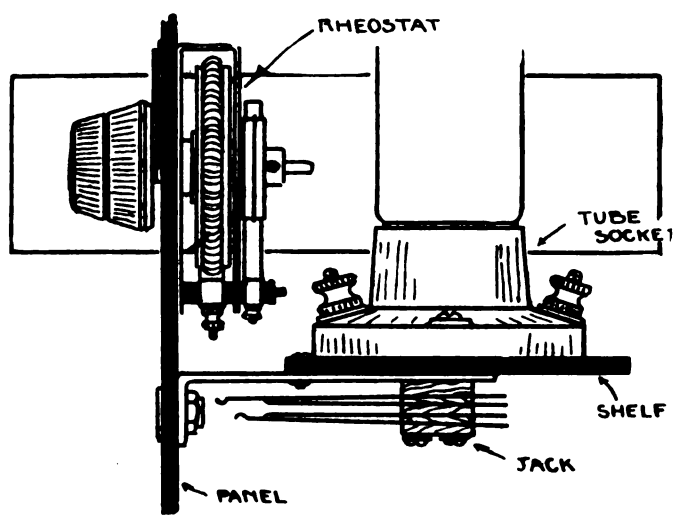
WHEN an amateur turns his constructive skill toward the building of what is known as a "double-decker" radio receiving set he fastens his midway shelf to the panel by either brackets or screws. This procedure necessitates drilling holes in the face of the panel, and it is also the cause of much annoyance, for all of us have had trouble in making such a shelf substantial. First, we thought we could drive in long, thin screws from the outside of the panel, but we found that wood splits easily when screws are driven into its edge. We also discovered that a shelf supported only from the front is unsteady, and the final outcome of our experience was the addition of two brackets, with the additional holes, trouble and time.

All this, although quite usual, is not in the least necessary. An amateur who was doing a lot of "double-deck" building wasted his time and patience so many times that he decided that if there was a better way of mounting a back-panel shelf he was going to find it. After much labor he finally hit upon the idea of inverting his telephone jack, using its base in the same way as a bracket, and thus mounting the shelf for the tube socket quite independent of the panel. When put into practice the idea resulted in a neat and novel back-panel shelf, easily constructed by any one with the fewest possible tools.

The shelf may be made out of either wood or bakelite, 2½ inches wide. The length of the shelf is determined by the number of tubes which are to be mounted upon it. For a single tube a strip of material 2½ inches long is about right, but for double or triple tubes the length must be proportionately increased. If only one tube is to be mounted there will be only one jack used as a support, while two tubes will call for one extra, etc.

The jacks are mounted on the panel in the usual way, but are inverted so that the metal bases are on top. Drill a hole in this base and tap it with an 8-32 machine thread. A corresponding hole in the shelf takes a machine screw, by which the shelf is fastened firmly to the jack. Of course, the strip of wood or panel material must first be drilled to take the tube socket or sockets, which must be placed so that there will be no interference one instrument with the other. The transformers may also be mounted on this shelf, either on the top and standing upright, or on the lower side hanging down.

The finished arrangement is not only neat, but attractive. It has other advantages, the chief of which are that it takes up very little room, shortens the leads to the various instruments, obviates drilling the panel, and is superlatively easy to apply, not only in single-tube sets, but also in receivers that boast as many tubes as a fellow has fingers on his right hand.



Space-saving method of mounting tube sockets.

Personality in Broadcasting

MANY broadcast listeners have become so immune to the romance of listening that they can simply tune their sets and upon hearing an announcer's voice say, without the least emotion or personal feeling, "Oh, that is WSB." Or else they will calmly announce the fact that they can recognize any one of fifty announcers without hearing the call of the station or the announcer's own letters. This, of course, is fine, but—wouldn't they rather listen to a program when the announcer makes them feel that he is telling them a personal secret and at the same time become so friendly that they feel they could go up to him on the street and say with a slap on the back, "Well, that was a corking program last night! I sure was surprised when you 'rang in' that 'cellist. He was great!"

Many have heard WEAF broadcast time after time, but how many can listen to the Sunday evening program when "Uncle Roxy" is speaking without having that "personal feeling" every time he announces? He is different from the rest and he demonstrates it. He doesn't announce as though it was a cut and dried affair which has to be done—he puts his personality into that little black disk and gives every listener an impression of interested friendliness. He introduces the performers in such a manner that you know that they are almost personal friends of both "Uncle Roxy" and yourself.

Why it is that more announcers have not tried this method is a mystery. Broadcasting is a personal matter and cannot be cut and dried. What difference does it make if they do crack a joke when announcing—they have the "air" and if a little humor will lighten the task of the performers and make them feel that they are working for friends instead of total strangers, think how much harder they will work to please and how much easier it will be.

When broadcasting, the announcer is not talking to mummies or inanimate objects, even though he is doing so through a conscienceless maze of modern scientific apparatus. He is talking to thousands—yes, hundreds of thousands of people who possess emotions that can be brought into play simply by manifesting his personality.

Completed Offical List of Broadcasting Stations in the United States

FOLLOWING is the third installment of an official list of commercial broadcasting stations in the United States as issued by the Department of Commerce, and is continued from last week's issue. The list is completed with this installment.

As new allocations of wave lengths to stations now operating on 360 meters are made by the Department of Commerce, the changes will be published by RADIO WORLD.

Readers who save these installments will have a complete list of broadcasters with their station calls, location, frequency, wave lengths and power.

Call	Station	Frequency Kcys.	Wave Length Meters	Power Watts

The Radio Woman

SOME women just can't help being meddlesome. Here's a friend of mine who never will know anything about radio "butts in" on her husband's plans and makes herself perfectly ridiculous. It seems he had planned to take his radio set to their Adirondack camp for the summer and had spent several evenings checking up a list of spare parts he might need. His wife saw the list and brought to bear on it her half-baked knowledge of radio lingo. She decided the list wasn't complete and hied herself to the nearest radio supply store. Then she made this speech to the astonished clerk: "We're going to take our radio set up to our camp for the summer and, with it, a lot of spare parts. My husband has made a list, but he's forgotten something. I'm going to help him out and I want you to measure me off two 450 meter waves, so that if one breaks we'll have another on hand!" Isn't that the limit? The clerk told

(C. Kadel & Herbert)
Baby Ralph Breslin listens while mother prepares the muffins.

the husband, he told my husband, he told me and now I'm telling you. I hope my woman friend buys this issue of RADIO WORLD—and reads it!

* * *

I've been reading a lot lately, it seems to me, of how carefully tubes must be mounted to prevent jarring and breaking the filaments when the set is moved about. In one of the big department stores the other day I saw some sports shoes with soles of what they called "crepe rubber." It was about half an inch thick and very spongy in appearance and feeling. Why not make pads of this crepe rubber and mount the tubes on them?

Changes in Broadcasting Stations

ELEVEN new Class A stations were licensed by the Department of Commerce during the past week, eight Class C stations transferred to Class A, and two transferred from Class C to Class B.

SUPPLEMENTAL LIST OF LIMITED COMMERCIAL BROACASTING STATIONS

Call	Station	Frequency Keys.	Wave Length Meters	Power Watts
K F J A	Central Power Co., Brand Island, Neb.	1230	244	100

How to Make a Single Circuit Regenerative a Phantom Receiver

By Leon W. Bishop 1XP

ONE of the most interesting and spectacular circuits for a single tube may be constructed for vacation use and may be used in a car or at camp and requires little or no aerial. The circuit is an adaptation of the two Armstrong principles and it really produces distance and clarity for a small constructional cost.

The success of any circuit depends upon the constants, particularly this one which would seem to be a standard regenerative circuit but is completely changed by a large tickler and variable grid leak.

This circuit has been designed for the new wave bands of 2,000 to 550 kilocycles (150 to 545 meters) which includes the amateur. The circuit is more efficient on the shorter wave bands so it is possible to get the Class B stations as loud as the Class A stations which is not possible with other types. Due to great flexibility the circuit will work equally well on phone, CW, ICW, and spark which will insure all classes of service no matter where located.

When using this one tube circuit in a car with a four foot aerial it is equal to a three stage radio-frequency amplifier and detector. Due to the short aerial used it is possible to receive through bad QRN and for this reason alone is of considerable value during the summer months.

The best tubes to use are the UV 199 and UV 201-A. The rheostat should be that resistance advised by the makers of the tubes. The B battery can be anywhere from 45 to 90 volts but maximum results will be obtained at about 65 volts. The two fixed condensers .00025 and .002 should be of the mica type. The variable condenser should have from 17 to 23 plates (.0003 to .0005 MF).

The variable grid leak is important and should be variable over a range of from 50,000 to 5 megohms. Several commercial types that were tried did not have the range they claimed so it might be advisable to build your own and for that purpose purchase a ten cent roll of Dennison's black picture binding paper tape whose dull black surface is slightly conducting and can be readily lowered with an extra soft lead pencil. This grid leak can be arranged with a sliding arm or switch and contacts but it must be variable over a wide range and capable of fine adjustment.

Like the grid leak the coupler is of special design and the following values should be adhered to. The best combination to use is the rotor and stator of a standard coupler wound as follows: The tube (stator) should be wound with as large a wire as possible starting with 20 turns on the rotor side of the tube and tap off every ten turns until you reach 120 turns which will leave 11 taps.

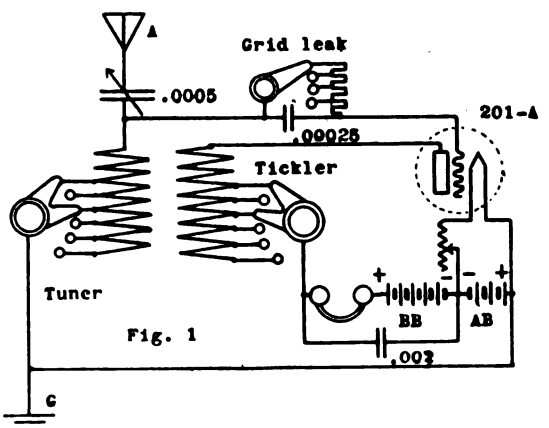
The rotor is also a real job for it is tapped in a similar manner. Start on one side of the rotor with 40 turns and tap off every 10 turns until you have wound on 120 and you will have nine taps. These taps can be passed through the rotor shaft to switch points on the panel or a switch may be mounted on the rotor. Fine wire may be used on the rotor to accommodate the 120 turns necessary.

A warning is issued against the use of shellac on the windings. Firm windings may be obtained by drilling holes at each tap off and binding the wires in them.

Do not use honeycomb coils. Either double or single switch arms may be used. The 180 degree type of coupler can be used. Do not tap the coils any coarser than 10 turns but finer if anything.

The best antenna or collector system is to connect the variable condenser at point A of the diagram to a good ground. No other connection is necessary. There are five adjustments on the set—1, the grid tuning coil; 2, the tickler coil; 3, the coupling between these coils; 4, the variable grid leak; and 5, the variable condenser.

As the tickler coil and grid leak are increased a regenerative condition will be met, which is denoted by a high pitched whistle, the pitch of which can be varied by the grid leak and should be adjusted until it is above the point of audibility and only a slight hiss is heard in the phones. At this point a wonderfully sensitive condition exists for all classes of phone and



Comprehensive circuit diagram illustrating a good single circuit "phantom" receiver.

CW and will tune in contrastingly clear as compared with any single tube circuit.

A given wave length is tuned in by means of the variable condenser and grid circuit tuning coil. The tickler and grid leak are merely adjusted to conform to this condition. The resistance of the grid leak should be so arranged that it will give out a bad screech as it is increased and follow through an intermediate series of pure notes until it passes out of audibility with a range of adjustment on either side.

The right polarity of the tickler coil in the plate circuit will have to be tried out by reversing the leads until the best results are obtained.

This is a standard circuit and may be used as such with an aerial and ground by reducing the tickler coil turns with the switch. With an aerial and ground the circuit can be used for transmission with a power tube and increased B voltage. All classes of super results may be obtained which makes it an ideal vacation outfit.

There are several aerial combinations that work well. One of the most interesting is to connect the point G to ground and touch the moistened finger to point A. For apartment houses two combinations can be used—connect the point G to ground and the point A to some metal object or a small aerial in the room, or connect just the point A to ground.

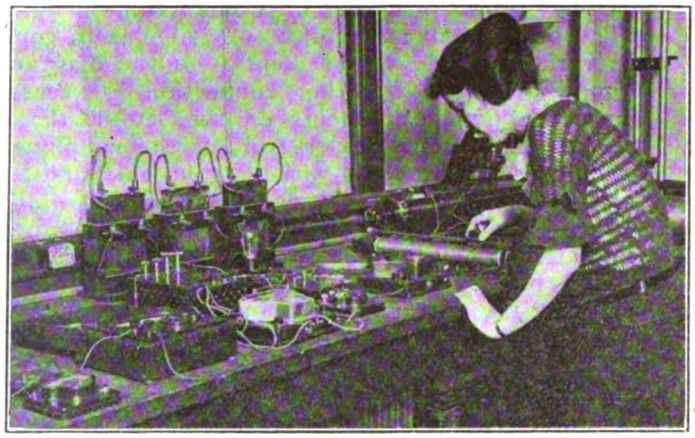
Of the Myriad Interesting Radio News Are Typi

BARNARD GIRLS ENJOY RADIO RESEARCH

The Department of Physics of Barnard College, New York, has some of the most interesting radio research apparatus and laboratories in the city. The most interesting and intriguing part of it is that the course is for girls alone, and that they are studying this research work as a part of their regular college work, and will be graduated with the degree of R. E.

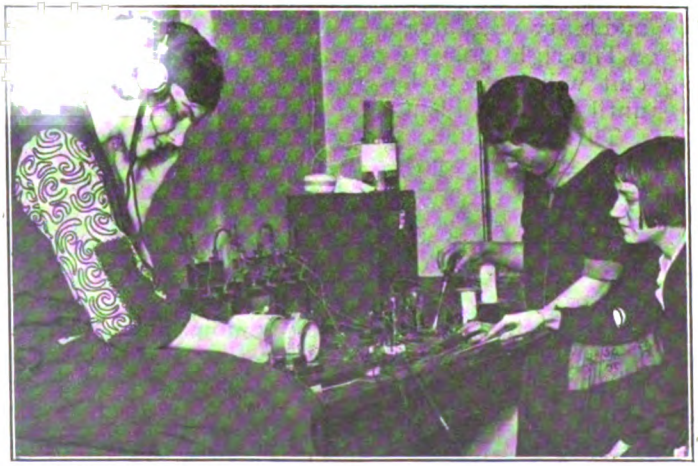


(C. Kadel and Herbert)
Miss Irene Bowman, class of '23 of Barnard College, determining the operating characteristics of a U. V. 201. The most up-to-date laboratory research apparatus is necessary and is used.

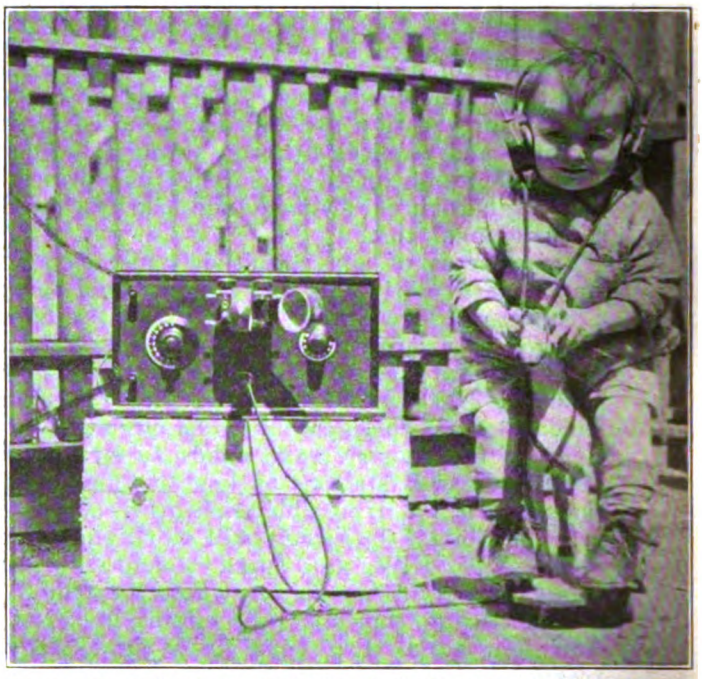
The course is a most extensive and practical course and takes in the theory and actual practice of radio. The girls have a very complete laboratory, where they can work out all the problems and prove out to their own satisfaction the deep, deep theories of all the master minds of the radio profession.

To give a slight idea of the extensive work that they are doing, just look at the illustrations and see them studying tube characteristics and work out neutralizing capacities for different styles and types of tubes. It is deep stuff, but interesting, and watch them go when they can tell the profession that they are full-fledged R. E's.

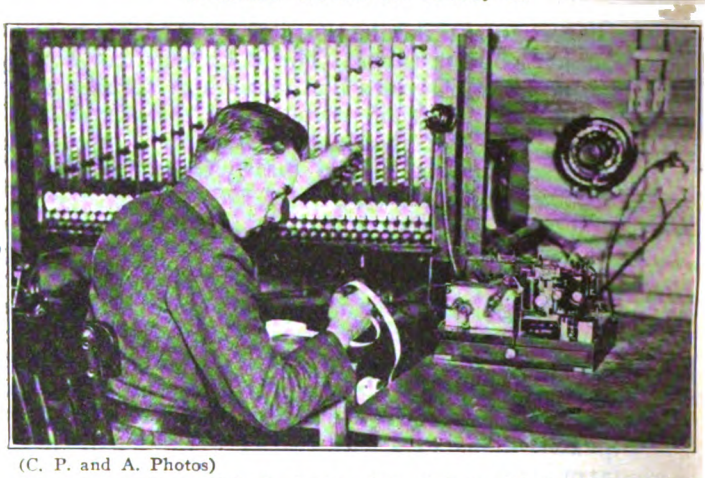
Captions by Robert L. Dougherty



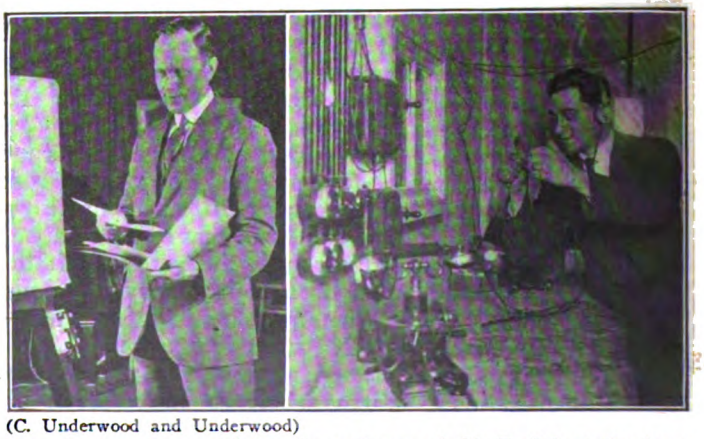
(C. Kadel and Herbert)
Miss Olive Gunn, class of '24; Miss Ruth Bass, class of '26; Miss Barbara Collison, class of '26, and Miss Lillian Willson, class of '26, studying the effect of neutralizing capacities on the operating characteristics of a three tube set.



Master Henry Pavel, Jr., of Astoria, L. I., has taken such a liking to Daddy Pavel's radio set that he has to have it out in the play yard in the garden with him. Although only a beginner in the art, he is a "mean dial twister," and would rather hear Uncle Roxy than twist the cat's tail, which is some reformation. The set used is the Sorenson circuit described in RADIO WORLD for January 20.



(C. P. and A. Photos)
Apparatus at Camp Vail, N. J., by which it is possible for the students of telegraphy and radio to quickly see their faults by comparing their transmission with one that is machine sent and perfect. This is possible by comparing the two which are recorded on a moving tape. There are 115 men and officers at this camp devoting their time to radio and signal corps work.



(C. Underwood and Underwood)
How the control man informs the performer of this English station how the music is being transmitted. A window communicates between the studio and the operating room, and visible signals are used as shown. Wonder if "thumbs down" means show emotion or run?

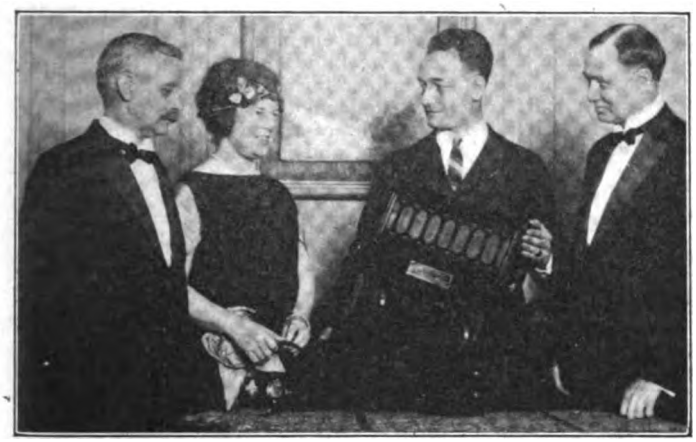
s Events Constantly Occurring These ypical

(C. Keystone View)
It's perfectly wonderful getting your boots slicked up in this shine parlor, if you live in San Francisco. But don't possess a pair of "musical ankles" if they start in to broadcast a good lively jazz while trying to get a shine for church.



(C. Photonews, N. Y.)
Edith Bennet, American concert star, was presented with a full-fledged and complete radio set at the Hotel San Remo when a banquet was held in her honor. The set was donated on behalf of Miss Bennet's efforts for the unseen radio audience some time ago, when she sang the first concert broadcast across the Atlantic.

(C. Kadel and Herbert)
Instead of the usual sleeping potions and drugs they are now serving neurotic patients in all the big hospitals and sanatoriums with a light dose of fresh caught radio music and talk. Doctors claim that it quiets the nerves and soothes the patients much better than the usual harmful habit forming drug. Even nurses like it.

WHN IS A POPULAR STATION WITH THE FANS

The call letters of this station have been heard far and wide despite the fact that it is a comparatively low-power station among a forest of high-powered brethern. This station, although using only 200 watts output, can claim the distinction of being heard in Cuba and Panama, and

(C. Kadel and Herbert)
Chief Operator F. W. Boettcher doing his "daily dozen" in adjusting and checking the wave length of Station WHN, well known and liked by the many listeners.

it is through the co-operation of the studio and the people in the surrounding territory that WHN has gained the name of "One of the most popular broadcasting stations in the East."

The accompanying illustrations show the personnel of the station that tend to make this station more and more popular through combining the public's wishes with their programs and making the people feel that they have a personal interest in WHN.

(C. Kadel and Herbert)
Staff of WHN. Left to right: Robert Pierce (late of WJZ), Mrs. Catherine Chute, Charles Reed Jones, Miss Pauline Kinkel, F. William Boettcher (Chief), Miss Adeline Rabe, Louis F. Mueck. Sitting: Madeling Jonk, Carl Klemmens. Up above the crowd is J. L. White.

A feature of Children's Day, which was celebrated by hundreds of churches, was the broadcasting of a full "Children's Day Service" from Station WJZ in commemoration of the golden jubilee of the occasion.

* * *

Edward Lind Morse, artist, author and son of Samuel Finley Breese Morse, inventor of the telegraph, died last week at his home in Pittsfield, Mass., at the age of sixty-six. His portraits and landscapes are in many American art museums. His principal literary work was "Samuel F. B. Morse, His Life and Letters."

* * *

Max Graf, president of Graf Productions, Inc., has found a new way to get in touch with the theatre-going public. It's via radio, and last week the producer spoke to the public from WJZ in the Aeolian Building, New York City. His idea, Mr. Graf explained, was not to get publicity, but to ask all those listening in on his speech to write him what they wanted in motion pictures.

* * *

The dancing which followed the recent Shriners' pageant in Washington, D. C., was intended to represent "a united country in step." The music was broadcast by radio throughout the continent and was carried to the thousands of participants through amplifiers along Pennsylvania Avenue. Each block was set aside for a State, and the spectators along the line were invited to join the 140,000 Shriners and their visiting companions in the festival.

* * *

Holger H. Hansen, of "El Ejemplo," Humacao, Puerto Rico, sends to RADIO WORLD a clipping of a public notice signed by Governor Henry H. Hough of the Virgin Islands, reading as follows: "It is hereby brought to public notice that, in pursuance of the provisions of the ordinance approved 28 May, 1910, it is unlawful to establish or maintain a radio or wireless station, public or private, in the Virgin Islands of the United States without the express authorization of the Governor of the Virgin Islands of the United States of America. Violations shall be punishable as prescribed by Chapter I, Section 6, of the ordinance above mentioned."

* * *

It is the plaint of scientists that the public seldom recognizes their work until that work takes on some spectacular aspect, and the reproach is possibly justified, observes a writer in the New York *Times.* It causes them to be reticent with regard to their achievements for fear that the true significance of them may be lost in the attempt to impress them upon the public's mind by some vivid detail. But in the last few years the increasing interest in science because of its close relation to every-day life, the growing knowledge of its service to mankind, has brought about a greater recognition of men whose work was unknown a short time ago except to their associates.

* * *

Thomas Alva Edison attended the graduating exercises of the Massachusetts Institute of Technology at Cambridge, Mass., last week. His son, Theodore Miller Edison, was a member of the graduating class to receive the degree of Bachelor of Science. When asked if he would give his son a job without requiring him to answer one of the famous questionnaires, Mr. Edison is quoted as saying: "My son is a physicist and mathematician, and I am no mathematician. If his mathematics are not too professional he can work with me, but if his mathematics shoot off in the Einstein direction he'll be practically no use at all." Asked why he allowed his son to go to Tech, Mr. Edison is reported to have said: "There is some hope for men who come out of Boston Tech. When they come out of Harvard, Yale and other colleges they 'leave all hope behind.'"

Gerard Swope, president of the General Electric Company, received the honorary degree of Doctor of Science from Rutgers College at the recent annual commencement.

* * *

British authors, playwrights and composers have decided they will not permit the broadcasting of their works by radio unless they receive payment for the use of the material.

* * *

Radio communication is rapidly being adopted by Western power companies as a means of maintaining communication with their distant power plants when wire lines are inoperative.

* * *

Governor Smith of New York last week gave an account of his stewardship and explained in detail the various appropriations he has approved. His statement was broadcast in full from Station WGY, Schenectady, N. Y.

* * *

A fund for the purchase of a library devoted to the science of radio has been established at Yale University by Dr. Lee De Forest, who is a Yale graduate. Dr. De Forest has also established a fund for a course of thirty lectures by radio experts for the benefit of the engineering staff.

* * *

Dr. Louis Bell, widely known electrical engineer, died at his home in West Newton, Mass., last week. He organized the course in electrical engineering at Purdue University, was editor of the "Electrical World" two years and chief engineer of the Electric Power Transmission Department of the General Electric Company three years. He designed and installed the first polyphase power plant in this country.

* * *

A British explorer named Buchanan and his party of Arab natives were among the hills of the Sahara Desert when he slipped and fell nearly 100 feet, sustaining bad bruises and internal injuries. Natives carried him fifty miles to the nearest wireless station, a far-flung outpost of the French, over 500 miles from civilization. By wireless the French got in touch with doctors at Algiers and ascertained how to treat Buchanan. Three days later he and his party resumed their march.

* * *

In an effort to decrease governmental radio interference, a special committee composed of members of the Interdepartmental Advisory Committee on Radio has made a study of wave frequencies used by the government, and recommended certain changes to the Department of Commerce. In view of this Secretary Denby, of the Navy, has requested that a complete survey of all government radio activities be now undertaken by this committee so that complete co-operation and co-ordination may be had.

* * *

Chandler Goldthwaite, the brilliant young American organist, who for the last two years has been at the console of the St. Paul Municipal Auditorium organ and enjoys the distinction of having played to the largest audience in the world, sailed for Europe recently. Before leaving on his European concert tour, Mr. Goldthwaite played several Sunday night radio organ recitals which were broadcast from the studio of the Skinner Organ Company, New York City, through Station WEAF.

* * *

High voltage experiments were conducted at the Pittsfield, Mass., laboratories of the General Electric Company last week during which a realistic electrical storm was manufactured for visiting engineers and newspaper men. All were duly impressed as each had to sign a waiver against claims for possible injury before entering the laboratory. It is estimated that a voltage of 2,000,000 was attained, which is said to be twice that ever before employed in similar experiments. Arcs were sprung between terminals over 15 feet apart.

* * *

A program of singing and addresses was broadcast for the first time simultaneously from four widely separated stations—WEAF, New York City; KDKA, Pittsburgh; KYW, Chicago, and WGY, Schenectady, N. Y.—which were connected by direct telephone wire with the stage of Carnegie Hall, New York City, where the recent convention of the National Electric Light Association was in session. As a result many hundreds of thousands of radio fans in this country and Canada were able to listen to the singing of Miss Anna Case of the Metropolitan Opera Company and to the talk of Julius H. Barnes, president of the Chamber of Commerce of the United States. The transmission of the voices over the telephone lines was so clearly instantaneous that the four radio stations broadcast the proceedings at virtually the same second.

Answers to Readers of Radio World

I HAVE three small De Forest honeycomb coils and two others of another make which are the largest manufactured. With the De Forest I can put them in a circuit with a buzzer or bell and make the circuit, but with the others, I cannot do this. Is this an indication of a break in the coil? Will a one-tube reflex set allow me to get WJY and WJZ on a loop with anything like fair volume?—F. N. Cash, Norwich, Conn.

This is not an indication of a break in the coil. As the larger coils have considerable resistance it is hardly possible that you could ring a buzzer or bell with such a coil in the circuit. They have thousands of feet of fine wire, and the resistance is very high. A reflex set on a loop should enable you to get the stations you desire, if it is carefully made and tuned.

* * *

Kindly advise me what materials I would need for a reflex circuit similar to the De Forest. What is the circuit used? What type R. F. transformers are used in the De Forest reflex and are same available on the market? Is it advisable to make your own transformers for this type of work? What is the tuning done with when a loop is not used and antenna and ground is used in the De Forest D7 reflex? Is this type of set selective?—Howard W. Root, Derby Line, Vt.; A. G. Morris, 967 Fulton Street, Brooklyn, N. Y.; Allen Beardsley, Arlington, Va.

The necessary apparatus for the De Forest type reflex set would consist of three radio-frequency transformers, two audio-frequency transformers, three tubes with sockets, one rheostat (single control), one potentiometer, one crystal detector, one variable condenser, one coupler, one loop and fixed condensers as specified in the diagram. The circuit used is shown herewith. The R. F. transformers that are used in the De Forest are not available as they are especially manufactured for these sets. It is decidedly cheaper to buy your transformers than to make them, as the product that you buy is as perfect as research work and skilled workmen can possibly make them. It takes more than a knowledge of how to wind them, as various factors such as the internal impedance of the tubes and various other technical details have to be considered, and a home-made transformer could not be any more than a makeshift unless all the data was worked out before hand as it is done in the laboratories. In this set when the loop is withdrawn from the jack, it automatically connects the secondary of a tuner in the circuit, and the set can then be tuned by means of an ordinary variocoupler and the secondary condenser. This set is highly selective and the tuning on it is very sharp.

* * *

In RADIO WORLD *for February 10 you published an article concerning the making of a spiderweb coil tuner. Will paper forms be permissible to wind these on? The forms are to consist of thin white paper fastened together with clear varnish. Why is not slate used for forms such as this in radio work?—W. A. Bond, Hotel Irving, Greenwood, Miss.*

Would suggest that you use cardboard formers instead of white paper varnished as you mention. Paper would not have sufficient body to support the coils, and winding with varnished paper as you suggest would have a tendency to give a capacity effect between turns of the winding. The best material for this purpose is either thin mica sheeting, fibre board, bakelite sheeting, or heavy cardboard impregnated with wax or paraffine. Slate is not suitable for two reasons. The first is its working qualities and the second is that it is not a good insulator of high frequency currents. Slate is extremely brittle and hard to cut and shape, and using it for formers in such a winding would lead to innumerable troubles in the cutting and drilling. Don't court trouble in trying to work slate unless you have ample stone cutting facilities and experience in working this material.

* * *

In the June 2 issue of RADIO WORLD *you published a hook-up of a single tube reflex circuit using two RF transformers without description or specification as to what ratio or make to use. Kindly let me know.—R. B. Bannard, Hyde Park, Mass.*

If you will refer to the diagram you will see that there is one **audio-** and one **radio-**frequency transformer used. They are labeled AFT and RFT. The audio-frequency is shown as a metallic cored transformer and the radio-frequency as an air core transformer. We cannot specify any make of transformers in our descriptions or articles. Buy the best you can afford and be satisfied that your results will be good. As stated numerous times before, "cheap apparatus gets cheap results—good apparatus satisfies."

* * *

In RADIO WORLD *for May 19, R. N. King writes an article entitled "The Pup drags It In" and gives a list of stations heard on the set. What issue did this circuit appear in?—A. R. Gurnett, 64 Hallam Street, Toronto, Canada.*

This circuit appeared in RADIO WORLD for May 5 on page 7 with a complete description and panel layout.

* * *

Can results from the U. V. 199 tubes be expected to equal those of the old 200 or 201 tubes as detector and amplifiers? I am using these tubes in my set as detector and amplifier. With the use of 45 volts on the plate a decided decrease in filament supply is noted and the results obtained are nowheres near my old set. What can I do to remedy it?—Kenneth H. Jones, London Mills, Ill.

Under proper usage, these tubes will give wonderful results. The volume obtained when they are used as detectors is very near that when the U. V. 200 or 201a is used. Extremely careful operation of the filament rheostat is necessary to obtain the best results. When too much current is used, the volume of the received signals falls off appreciably. You should supply the filament current to these tubes through a 30 ohm rheostat in order to get correct filament current, and even then a fine vernier control is necessary. When these tubes are used as an amplifier a grid bias battery is necessary in the grid lead. This can consist of three cells of a flashlight battery in series for the first step, and two such units of three cells, or six cells in series for the second step. This has been found necessary when using these tubes as amplifiers and your volume will be found to increase greatly if it is done. As before stated, the filament current is very critical. This applies to the amplifiers as well as detectors. If your tubes work better with less B current at the amplifier it is perfectly O. K. to use less, but the fact that you have to decrease your filament current when 45 volts are used points out the fact that you are using too much filament current. Watch this point very carefully before getting impatient with your tubes.

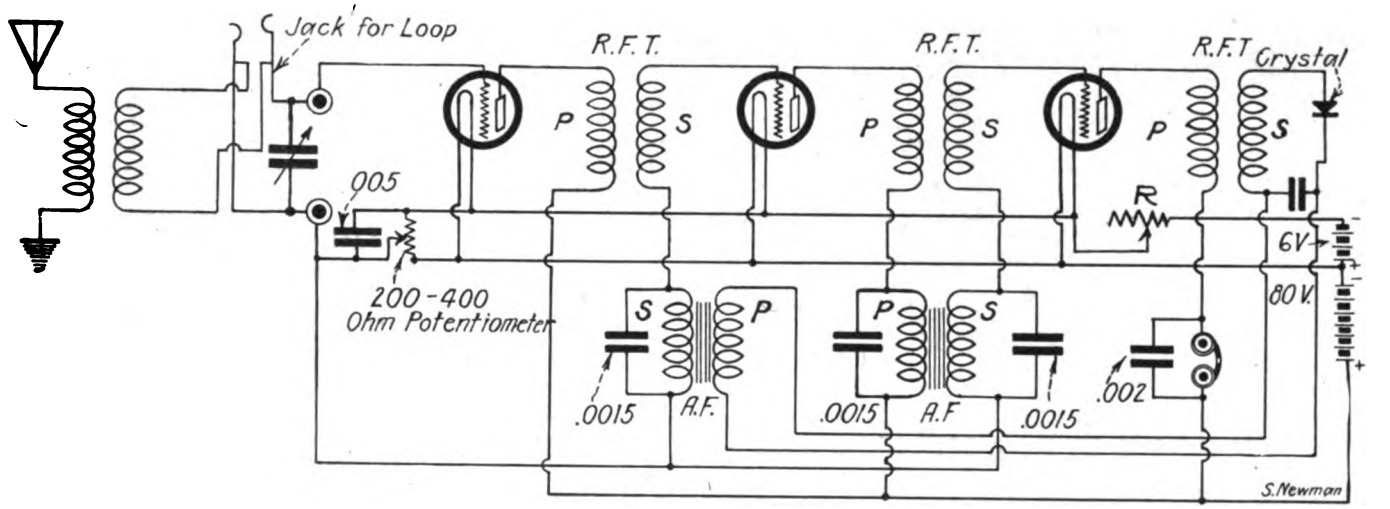

Diagram of the reflex circuit used in the De Forest D7 combination and antenna-ground receiver. When assembling a set of this type extreme care should be taken. A reflex circuit due to its action and construction will often not operate because some simple minor detail has been overlooked. If your circuit does not work, you may be sure that something has been done wrong in the construction and the fault is not in the circuit. Follow the diagram exactly, solder your leads and make them as short as convenient and be assured of success. Don't experiment with your own ideas.

Latest Radio Patents

Radio Receiving Apparatus

No. 1,455,141: Patented May 15, 1923. Patentees: P. D. Lowell and F. W. Dunmore, Washington, D. C.

THIS invention relates broadly to radio telegraph and telephone receiving apparatus and more particularly to a circuit arrangement for such receivers.

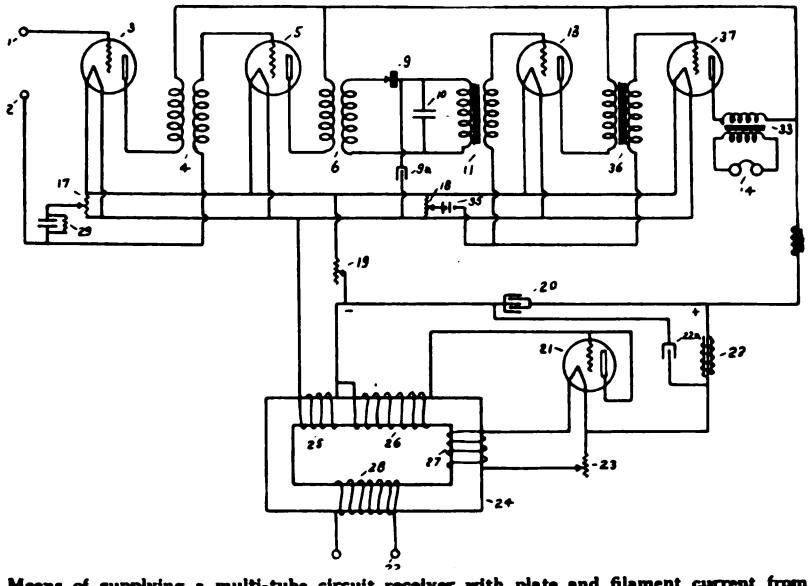
The object of the invention is to provide a receiver unit of maximum sensitivity employing thermionic vacuum tubes with their circuits supplied with energy from the standard alternating current residence lighting power.

Another object of the invention is to provide both radio and audio frequency amplification at the receiver and means for energizing the power circuits of the amplifier stages from the standard alternating current residence lighting power without interference in the reproducing receivers from the hum of the alternating current power supply.

A further object of the invention is to provide a circuit arrangement for a receiver wherein both the radio and audio frequency currents are amplified by means of electron tubes, a crystal detector used as a rectifier, the necessary filament and plate voltages being supplied by the standard alternating current residence lighting power, the residual hum in the telephone receivers being balanced out or neutralized by means of voltage dividers and other devices in the receiver circuits.

A still further object of the invention is to provide means in a radio receiver for transforming the alternating current power supply into currents suitable for the various circuits of the radio and audio frequency stages of the vacuum tube amplifiers and means for rectifying currents and obtaining a steady source of direct current potential for the plate circuits of the vacuum tubes.

Electron tube amplifiers form an important part of practically all radio receiving sets now, except the most simple types. Such amplifiers are in fact necessary to receive distant stations, or when using coil antenna. For good operation, amplifier tubes require for the filament a source of voltage of very constant value (usually about 6 volts) and for the plate a source of voltage of from 40 to perhaps 300 volts. The filament voltage is usually supplied by storage cells, and the plate voltage by dry cells. The maintenance of these cells in operating condition, especially the storage cells, is often a source of much difficulty and annoyance. The storage cells are necessarily bulky and heavy, require constant attention to maintain proper charge and density of electrolyte, give off injurious acid or other fumes and are subject to considerable variations of voltage during the period of discharge. The development of a receiver employing an amplifier which can be supplied from the ordinary 110 volt alternating current lighting mains is of considerable practical importance, since it eliminates the great practical difficulty of maintaining storage cells. The amplifier using such alternating current supply has the important advantages of reliability, convenience, and cheapness both in first cost and operating cost.



Means of supplying a multi-tube circuit receiver with plate and filament current from the commercial house current. A crystal detector is used, thereby eliminating any hum, which is further balanced out by an elaborate filter system.

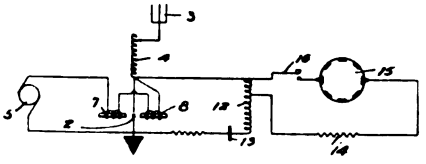
Radiotelegraph Signaling System

No. 1,454,624: Patented May 8, 1923. Patentee: Corwin C. Chapman, San Francisco, Calif.

THIS invention relates to radio signaling and particularly to single wave radio signaling.

Heretofore, signaling with continuous oscillations produced by an arc radio generator has involved the radiation of oscillations of two frequencies, one being the signaling frequency or wave, and the other being the compensating frequency or wave. Signaling has usually been accomplished by variation of antenna inductance, which variation altered the frequency of the radiated wave, so that two waves of different frequency were radiated by a station during signaling. In order to avoid interference, it was necessary to assign two wave lengths to each station and as the number of stations have multiplied, confusion and interference has been caused by the radiation of oscillations of two different wave lengths from each station.

An object of the invention is to provide a system of single wave radio signaling, in which waves having a frequency above the limit of audibility are converted into signals having a frequency within the range of audibility. The arc radio generator produces continuous waves having a frequency above the range of inaudibility, but many receiving stations are not equipped to receive and identify waves of such frequency. This invention, therefore, contemplates so manipulating the high frequency waves that signals will be received by such stations and this is preferably accomplished by converting the continuous wave into wave trains or wave groups, the frequency of the groups being within the range of audibility, so that signals so transmitted are readily received by all receiving stations. This is accomplished with the use of waves of a single frequency, thus eliminating the presence of the compensating wave. With my invention, there is utilized an absorbing oscillatory circuit in shunt with the transmitting circuit so that intermittently this shunt circuit absorbs substantially all of the energy of the source.

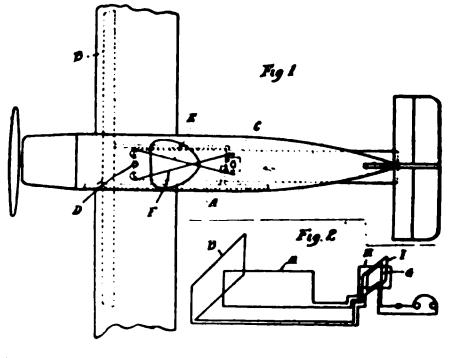


Method of using continuous waves for signaling without the necessity of generating two separate waves.

Method of Piloting Aircraft

No. 1,454,582: Patented May 8, 1923. Patentees: H. R. C. Van de Velde and J. M. Furnival, Bromley, England.

THE object of this invention is to provide improved wireless direction findings means whereby the pilot of any type of aircraft can automatically find his way. We connect the moving part of any ordinary direction finding means in which the maximum or minimum method is employed either to the rudder bar controlling the direction of flight of the aircraft or to any auxiliary attachment thereto. One method of applying the system is shown in the accompanying drawing which illustrates the standard Bellini-Tosi system. In the drawing: Fig. 1 is a plan view of an aeroplane having a direction finder in accordance with the invention. Fig. 2 is a diagrammatic view showing the angular relation of the coils of Fig. 1.



Antenna system for obtaining directional effects as applied to aircraft. A double balanced loop system is used.

Whereas They Were Deaf, They Now Hear Again—By Radio

RADIO has broken the shell in which I have been living for forty-five years. There are something like five million people in the United States more or less hard of hearing. Only a few realize what the new discovery means to them. I'd like to go down to Wall Street and stand on the Treasury steps beside Washington's statute to preach the gospel of Saint Radio!"

That is the voice of the man who cares nothing for the process, mechanical or psychological; he wanted not reasons but results. Whereas he was deaf, now he hears. But already the Section on Otology of the American Medical Association has begun to discuss the scientific aspects of radio for the deaf and a paper read at Atlantic City a few days ago expressing a favorable view will soon be published in the medical journals as a basis for general discussion.

A powerful radio set has been placed in the headquarters of the New York League for the Hard of Hearing, at 126 East Fifty-ninth Street, and is enthusiastically used by the members, eight or ten at a time holding the ordinary telephone receivers—a temporary makeshift. Within a few weeks an elaborate installation will be completed with individual receiving apparatus for fifty auditors. The adaptation of radio to the hard of hearing is a delicate process which will take time and ingenuity to work out. But the beginning has been made.

The words of the first paragraph were spoken by Warren Pond, the newly elected President of the New York League. To get the full effect one must imagine him at his office desk—a grave, white-bearded gentleman in the early sixties—busy checking up the count of thousands of songs that lie silent on their separate shelves waiting to be sung or danced or played. The room is lined with these little honey-cells of prisoned music. Just a century ago Mr. Pond's grandfather issued the first composition way down in old New York. His father was Stephen Foster's publisher. There is something ironic in his own activity, forever sending out the notes of a music to which his ears were closed.

The look of the shop suggests years of business history. The look of the man suggests reserve. In sharpest contrast come his words—the irrepressible wonder and delight of the convert.

"My friend Fletcher here used to come in day after day and tell me the fun his boys were having with their set. I paid little attention at first, having learned by hard experience not to put myself in the way of disappointment.

"But my friends kept insisting, and finally made an appointment for me to listen in. I heard enough to decide to have a machine of my own. It had to be a powerful one—there are six tubes—and I used up the first battery in two days!

"I'm not ashamed to confess that when the set came, as I sat there and heard clearly, in my own home, the first notes of a song, the tears came to my eyes. It was the beginning of a new life.

"That was less than two months ago. In these few weeks I have had more of the pleasure of hearing than in forty-six years. When I was 15, typhoid fever left me with impaired hearing. The trouble has grown worse since."

Any one who has talked with partially deaf acquaintances on the telephone has probably noted that they hear much better than when spoken to face to face. In the receiver the vibration is intensified, the sound sharpened. But Mr. Pond long ago passed even the stage where that would help him. He does not use the telephone at all.

For necessary conversation he carries a sound-magnifying device consisting of an earpiece, a short wire and a little box to be held near the speaker's mouth. This affords too limited a contact with the world for a man with a curious, exploring, social mind.

There are two things that Mr. Pond craved with a desire comparable to hunger—music and a direct, personal, human report of other men's doings. He could read and he could go to the movies. But they left him still unsatisfied.

"I would go to concerts once in awhile," he said, "hoping to get a few of the louder strains, a little phrase of melody to remember. Last year I heard Guilbert sing—that is, I heard an occasional high note."

He was like the small boy who stands wistfully outside the baseball grounds watching the top of the celestial wall for a glimpse of the rare fly batted by an invisible hand.

"One who has good hearing can scarcely imagine the terrible effort required of us by a single concert. I have come away exhausted and suffering in all my nerves. The little pleasure won is blurred by the strain of listening.

"So you can see how many different kinds of satisfaction we get from the radio. First there is the relief of hearing without effort. Then we get the entire selection where we used to feed on scraps.

"You may think Rubinstein's 'Melody in F' is a hackneyed old thing. But it gave me the richest of thrills the other day when I heard it for the first time in years, every note, all the way through. The glorious completeness of it!

"Let me tell you what I heard last Sunday. First, the full morning service at St. Thomas's Church—hymns, anthems and sermon. In the afternoon an address by Dr. Cadman with music by the Gloria Trumpeters. An organ recital ended the day.

"Another Sunday I was present—by radio—at a service where new members were received into a church. There is a good deal of detail in such an affair and it offers a severe test. I heard everything.

"It may not sound very thrilling to the man with good ears, but try to put yourself in my place. Of course, temperaments differ widely. I suppose I care more than some folks do. There is Edison. He invents devices to help the deaf and never uses them himself.

"Of late years I have gone a few times to opera, but I heard so little that there was more fun in taking time for a good dinner. This spring I heard Martha clearly, and I'm looking forward to the orchestral concerts they will broadcast next season.

"This thing has just begun. I wish I were twenty years younger to be in on all its developments. A few weeks ago it was enough to hear the stations close by. One gets ambitious. I want to hear the surf break on the South Sea Islands now.

"Yes, it costs money if you're very deaf. But who wouldn't pawn his watch to get to the gates of Heaven? They joke about those poor fellows who make excuses to slip off to the golf links or baseball. I sneak home early myself, but some day I'll do better than that. I'll have a set installed here in the office, and when work is slack there will be no time wasted."—*New York Times.*

MAGNAVOX
Radio Products

R3 Magnavox Radio The Reproducer Supreme

Make Your Receiving Set Complete

The efficiency of the Magnavox Reproducer is due to its principle of construction.

Only the Magnavox (electro-dynamic) reproducer can re-create broadcasted programs according to their original *pitch, quality* and *volume.*

Without Magnavox equipment, no Radio receiving set is complete.

Magnavox R3 Reproducer and 2-stage Power Amplifier . . . **$90.00**

R2 Magnavox Reproducer with 18-inch curvex horn: the utmost in amplifying power; requires only .6 of an ampere for the field **$60.00**

R3 Magnavox Reproducer with 14-inch curvex horn: ideal for homes, offices, etc. . . . **$35.00**

Model C Magnavox Power Amplifier insures getting the largest possible power input for your Magnavox Reproducer.

AC-2-C, 2-stage, $55.00
AC-3-C, 3-stage, $75.00

Magnavox Radio products can be had of good dealers everywhere. Write for copy of our new booklet.

Following R. C. A. Injunction DeForest Changes Its Dealer Policy

HEREAFTER the DeForest Radio Telephone & Telegraph Co., Jersey City, N. J., will sell directly to the public through exclusive agents only. Information from the DeForest Company is to the effect that an injunction has been granted to the Radio Corporation of America preventing the DeForest Company hereafter from selling radio merchandise through the usual trade channels of jobber and dealer.

This injunction is said to be based on a contract made by Dr. DeForest with the American Telegraph & Telephone Company, March 27, 1917, which stipulated that the DeForest Company would sell radio apparatus for amateur and experimental use only and to users who would purchase this apparatus only for individual use, and not for purposes of resale.

Complying with the court order the DeForest Company therefore announces that it will now sell direct to the public through exclusive agents, who will accept DeForest apparatus on a consignment basis only, in accordance with an explanatory letter which was sent out by the DeForest Company toward the end of last month.

The DeForest Company is now appointing these exclusive agents all over the United States. The agents' territory will be exclusive, and the new arrangement, according to the company, presents many advantages for DeForest agents which were not possible under the old arrangements.

Date Set for New York Radio Show

J. C. JOHNSON, manager of the American Radio Exposition, announces that the next show will be held in the Grand Central Palace, New York City, from October 6 to 13, 1923. Information may be secured from Mr. Johnson.

American Radio Prices Too High for Holland

AMERICAN radio manufacturers ask too much for their radio apparatus and materials to secure the Dutch trade, according to Consul Mahin, at Amsterdam. Competition from other countries, especially Germany, is reported to prohibit Dutch interests doing business with American exporters although the demand for radio telephone sets is good in Holland.

Canary Islands Considering Wireless

VICE CONSUL PHELAN, in the Canary Islands, reports active discussion in the Cabildo Insular de Teneriffe of a proposal to establish in the near future wireless telephone stations at the various islands of the archipelago. The present cable service between the islands has been very inefficient and has given rise to the suggestion of using wireless telephony.

"Radio, the Third Year"

AN interesting booklet has just come to the reviewer's desk from P. C. Kullman & Company, of New York, entitled "Radio, the Third Year." It is a history of the growth and expansion that has come about in this most fascinating field in the past three years—from the time that wireless was spoken of, if at all, as something of a "freak" to the present, when few are without some knowledge of its wonders. Two years ago there were no broadcasting stations. Today, in the United States alone, there are nearly 600. The Kullman book contains information as to the number of radio and wireless stocks, of the various companies engaged in allied activities, and other information illustrative of the magnitude of the industry that has developed with a rapidity hardly equalled in any other line.

Radio Lines Wanted for California

Editor, RADIO WORLD—We are anxious to get in touch with manufacturers of radio equipment, especially those who desire representation and distribution of their products in this territory. We have several very good lines which we are distributing and would like to add other lines to them. Anything you can do towards putting us in touch with such manufacturers will be greatly appreciated. Thanking you for your trouble, we are, Very truly yours,

YALE RADIO ELECTRIC CO.
4816 South Vermont Ave.
Los Angeles, Cal.

Radio in Hospitals Has Therapeutic Value

IT has been demonstrated more than once that music has a marked therapeutic effect on the spirits and general morale of hospital patients. In fact, a sixty-day test with phonographs has just been completed in the wards of the New York Nursery and Child's Hospital, 161 West Sixty-first Street, New York City. It showed that the waltz is good medicine and soothing. Well chosen music will now form part of the treatment of patients in that institution.

Here would seem to be an opportunity for up-and-coming radio dealers to increase their business in receiving sets. A systematic campaign among the hospitals, especially in the larger cities, should result in satisfactory sales.

How to Keep Dry Cells in Stock in Good Condition

DRY CELLS have become a part of the regular stock of the average radio dealer due to the fact that the dry cell tube has become popular. During the summer months quite a bit of trouble will be experienced by the dealer who carries a stock of these batteries, if certain precautions are not taken.

Due to a cell's chemical construction, it has a limited shelf life, after which it deteriorates. As the weather is getting warm a few simple rules will tend to not only increase the shelf life of dry cells, but will prevent the dealer from giving his customers batteries which will not last any length of time.

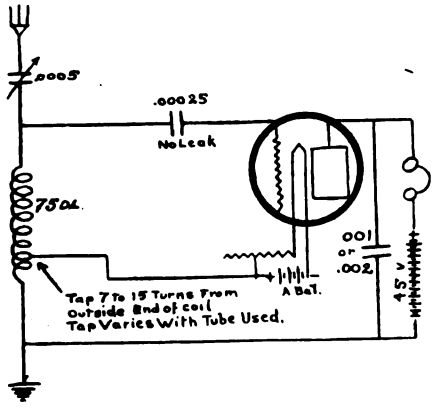
The first and foremost of these is to keep the cells in a dry place. During the summer months the humidity is high and frequently moisture gathers on the outside cover of the battery which helps to corrode the metallic lining of the battery, due to the fact that most of these metallic casings have chemicals on the outside, being handled and left in places where dampness is almost sure to collect on them.

It is most important to keep the cells in a cool place. Heat has a very noticeable effect on dry cells inasmuch as it speeds the chemical action which eats away the active elements. One dealer had a habit of keeping his cells on the topmost shelf of his store, because he thought that it was dry up there, and also "it kept them out of the way and gave an instant visual check as to whether we had them in stock." He was surprised to find out that various of his customers kept complaining that the batteries did not last any length of time, and his competitor down the street made mention of the fact that he was giving his customers old batteries. The first dealer knew that this was not so as he generally got his cells in the same shipment or at the same time that his neighbor did. He complained to the manufacturer and stated that he had had a cell in the house three weeks, sold it, and two weeks later the purchaser came back and told him that the cell was "breaking out" or was no good. The manufacturer sent a man up and he examined the dealer's stock and told him that it was a wonder that he had even kept the batteries that long. The temperature along the top shelf was 98 degrees at all times and when the heaters were going in winter or during a warm summer day it rose to as high as 110 degrees. This heat was continually wearing down the cells by speeding up the chemical action, much the same as a chemist heats a test-tube of chemicals to hasten the action, and not because the application of heat has any radical chemical effect on the constituents of the tube. Keep them cool, was the admonition of the expert, and you will keep them longer.

It is very easy for a space to be found near the floor where cells may be kept both cool and dry. If the stockroom is down below, it is much better to go to the expense of constructing a simple shelf on which to keep them off the floor and dry and cool at the same time.

A Modified "Pup" Circuit

Editor, RADIO WORLD: I have received best results with the "Pup" circuit when hooked up according to the diagram herewith. WOR was received when



Modified "Pup" circuit as worked out by Crumbaugh

weather conditions were considered bad here. You will readily see the departure from the regular "Pup" circuit.

Yours for better radio,
F. L. CRUMBAUGH.

Oskaloosa, Iowa.

Wireless Phone, Ship to Shore, in Denmark

THE United Steamship Company of Copenhagen, Denmark, plans to install wireless telephone equipment on all boats plying between Copenhagen and the provincial harbors for the traveling public's convenience. Travelers will be able to secure direct communication, through the land telephone service, with their own homes or offices similar to the service planned for the U. S. S. "Leviathan."

Radio to Be Used in Jersey Mosquito Campaign

NEW JERSEY has forty species of mosquitoes and some of them can travel at the rate of forty miles an hour, according to a statement made recently by Dr. H. H. Brinkerhoff, chairman of the Hudson County Mosquito Extermination Commission, which, he said, intended to employ radio in its 1923 war on this insect pest.

What Radio Fan Can Answer This?

EDITOR, RADIO WORLD—I am a regular reader of RADIO WORLD and like it better every time I get the latest issue. I can truthfully state that I have obtained more helpful information from RADIO WORLD than I have from all the various other radio magazines that I get. * * *

I don't remember ever seeing a column "open for discussion" in RADIO WORLD, but I am up against a proposition that I need some help on. The proposition follows:

During the week of May 14 to 20, I had my set, which is of the VT detector 2 stages AF regenerative type, installed on a steamer plying the Mississippi River. My aerial consisted of the usual two wire, inverted "L" type, about 100 feet long. This aerial was thoroughly insulated from the steamer but during the entire time that the steamer was under way there was an induced current in the aerial that was strong enough to break down from a one-quarter to a half-inch air gap. At one time while trying to tune in with the steamer under way the pilot blew a landing signal on the whistle. An extraordinary sparking, breaking down the air gaps on my 43 plate primary condenser, was observed. The sparking was correspondent to the signals, three long and one short from the whistle. There is one generator on the steamer supplying current for the lights and fans but this generator was not in operation during the day, and at night when the generator was in operation and the boat under way the induced current was not in the antenna. This same condition exists on one other steamer that I know of. The latter is equipped with wooden hull, while the one I was on was equiped with a steel hull. I would like to know *what set up the current in the aerial and what is the remedy?* I claim that it was due to the aerial cutting the magnetic lines of the earth. This has been disputed by some but so far I haven't been convinced as to the real cause. I would like to hear from any Radio Fan who has had the same experience or any that can offer a solution, as tuning in was practically impossible while the boat was under way.

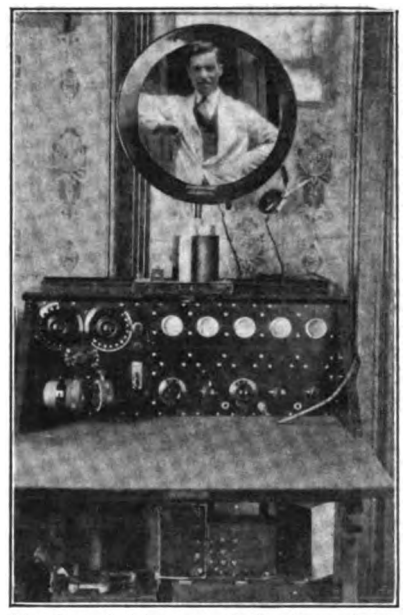
If you can enlighten me any at all on this subject I will certainly appreciate it. With best regards to RADIO WORLD and wishing it continued success,

E. M. PACE.

807 Cherry Street, Vicksburg, Miss.

A Good Home Made DX Set

EDITOR, RADIO WORLD—Some time ago I believe you said in RADIO WORLD columns that you would like to receive photos of home-made sets. Allow me to submit here-



Marchese looking out of the horn of his neat receiver

with a photo of my set which consists of two radio-frequency amplifiers, detector and two stages of audio-frequency amplification.

This set has an anti-capacity switch that cuts out the radio-frequency whenever you wish, thereby giving you the advantage of a common regenerative set. When you desire distant stations you have them by simply using the five tubes. For local work three tubes are sufficient to fill the house full of music.

The far off stations received with this set are: WSB, Atlanta: WOC, Davenport; PWX, Cuba; WDAP, Chicago; and about 50 others. Very truly yours,

STELLARIO MARCHESE.

3709 Avenue I, Brooklyn, N. Y.

"Safety First" Via Radio

Calling a man a liar over the telephone was the zenith of vicarious courage until it became possible to say, when a man is making a tedious speech over the radio, "Shut up, you big stiff!"—F. P. A. in New York World.

THE BOY MECHANIC

700 THINGS FOR BOYS TO DO

480 Pages—700 Articles
800 Illustrations — Cloth

Price $2.00 Prepaid

The Ideal Book for the Wide-Awake Boy

All the things described in this volume have actually been built or experimented with by boys. The ideas contained in "The Boy Mechanic" would more than keep a boy occupied until he grows up and also be an incentive to original thinking and achievement.

The Most Interesting Boys' Book

Unlike so many other books of a somewhat similar nature, it is not confined to only one or a few subjects, but describes 700 different things boys can make and do in the fields of mechanics, electricity, sports, arts and crafts work, magic, etc.

An unusually generous book; size 7 by 10 in. and 1½ in. thick; printed from large, clear type on high grade book paper and durably bound in cloth. Attractive four-color cover design.

Wholesome, Practical, Instructive

Besides telling how to make scores of things useful about the house, full and complete directions are given for constructing hundreds of things which appeal to the heart of every boy.

Many hours of enjoyment are in store for the boy who becomes possessor of this book.

CLASSIFIED ADVERTISEMENTS

Five cents per word. Minimum, 10 words. Discount of 10% on 4 consecutive issues—15% on thirteen consecutive issues. Cash with order.

Entered as second-class matter, March 28, 1922, at the Post Office at New York, New York, under the act of March 3, 1879.

IMPORTANT NOTICE

While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

Automatic Transmission and Reception

DURING the last ten years commercial companies developed automatic printing telegraph equipment for the transmission over land wires of typewritten characters from one point to another. The present means of copying signals with the tape required the employment of two or three extra men for translating purposes. Due to the reduction in operating personnel in the Naval Service, it became imperative to devise means to operate stations with reduced personnel. Experiments conducted in 1922 prove conclusively that automatic printing equipment could be applied to radio as well as to land wire. So much faith was placed in this new method of transmission and reception that automatic recording telegraph equipment has been installed in naval high power circuits at San Diego and Washington.

They Backed Down

NOW that the radio people have called the music publishers' bluff, and won out, it behooves the motion picture people to get busy and "follow through."—Exhibitors' Herald.

The Height of Efficiency
Crosley Model X—Price $55

Clearly, distinctly, as though given in the same room, messages from W. L. W. Broadcasting Station, Crosley Mfg. Co., Cincinnati, are heard in all parts of America if a Crosley Model X—a four-tube radio frequency set—is used. This remarkable instrument, very easy to tune, simple and beautiful in construction, has repeatedly brought in messages over 4,900 miles away.

RECHARGE YOUR OWN BATTERIES

WHY pay out good money constantly for recharging batteries when the Ohio Motor Generator will do it quickly at a slight expense. This inexpensive home charging outfit keeps your Radio in service all the time and pays for itself—by charging your neighbors' batteries. It is noiseless, gives no trouble, and will even recharge totally exhausted batteries quickly.

The set is made up of the celebrated Ohio A C motor and D C generator wound for 6-10 volts. The motor and generator have ball bearings and are of the highest grade construction. It has none of the troubles common to cheap charging sets and will last a lifetime. It will charge quickly any three cell automobile or Radio "A" battery. Furnished complete on a substantial base with ammeter and field rheostat to adjust the charging rate from one to twenty amperes. The motor is for 60 cycle, 110 volt service and is complete with ten foot cord and attachment plug ready for instant connection and operation. Full instructions provided.

Motor and generator can be specially wound to charge six cell batteries or other unusual conditions.

Price $38.50 f. o. b. Cleveland. Ship by Express C. O. D., weight sixty pounds. Send your order today and stop paying good money for recharging. Your money back quick if not satisfactory.

NOTE:—If your service is other than 60 cycle, 110 volt, ask for special price.

L. W. GOODMAN
DREXEL HILL, PA.

The GOODMAN is really a high grade instrument, well and sturdily constructed. The PANEL and FANS are GENUINE BAKELITE—the best material known for the purpose.

Easy—Just Like That!

"Pap," said the colored youth, "Ah'd like you to expiate on de way dat de telegraph works."

"Dat's easy 'nuf, Rastus," said the old man. "Hit am like dis. Ef dere was a dawg big 'nuf so his head could be in Bosting an' his tail in New Yo'k, den ef you tromp on his tail in New Yo'k he'd bark in Bosting. Undestan', Rastus?"

"Yes, pap! But how am de wireless telegraph?"

For a moment the old man was stumped. Then he answered easily: "Jess prezactly de same, Rastus, wid de exception dat de dawg am 'maginary."—Tid-Bits.

A Voice from the Farm

(From Station WOC, Davenport, Iowa)

The broad, free prairies on which we dwell
Stretch far to meet the sky.
Few travelers come, the news to tell;
No restless throngs pass by.
We listen to wild blizzards roar,
While chill winds fiercely blow.
The wild beasts' tracks around our door
Tell stories in the snow.
But though we're isolated thus
From all the world around,
Through boundless space there comes to us
The miracle of sound.
Can lonely places be on earth,
Where human voice can't go;
Or intercourse have any dearth,
Since we've found Radio?
Across a listening continent,
Through weather hot or cold,
Great waves of harmony are sent,
And children's stories told.
Babes cradled where the frost elves sleep
And icy north winds blow,
Are lulled to slumber sweet and deep
By songs the palm trees know.
When God so wisely formed the ear
For His creatures here below,
He made the law which lets us hear
Through vast space, by Radio.
I thank, Thee, my Creator high,
That I have lived to know,
While life is fleetly passing by,
The wondrous radio.

Laboratory Lightning

A GOOD deal has happened in the electrical world since Benjamin Franklin drew down his first spark from a thundercloud over a kite-string wet with rain, says an editorial writer in the New York *World*. Out of this experiment grew the lightning-rod, now popularly discredited, and out of a century and a half of experiment has come a control over electrical forces so complete that a bolt of artificial lightning of 2,000,000 volts, representing 10,000,000 horse power, can be manufactured and handled in a laboratory. Incidently, this test proved to the satisfaction of the scientists present that the lightning-rod did give protection after all.

But what is to be done with artificial lightning, now that we have it, is no more predictable than what was to follow Franklin's kite-flying. It may bore tunnels, dredge rivers or change iron to steel. It may turn out as handy as a pick and shovel and quite as harmless. And when the race gets accustomed to lightning as an every-day tool it may find a way to capture the voltage that goes to waste in any thunder-storm, may charge batteries with the weapons of Jove and hitch the dreaded thunder-stone to the belt-wheel of a power mill. Perhaps in time there won't be any thunder-storms, and artists will decry the commercialism that extracts the juice from the sky that used to make celestial fireworks. If these things don't come about, in all likelihood something more remarkable will.

All the family can tune-in with

ACCURATUNE

MICROMETER CONTROLS

Granddad, dad, mother and little brother all agree that "it is real joy to tune-in now with Accuratunes." A slight turn of the smaller knob operates the micrometer control for delicate tuning. Those stations you used to work so hard over, and others you could "just about get" are easily brought in clear and strong with Accuratunes. Knobs are of genuine Bakelite, either black or brown. Dial is silvered with neatly engraved graduations. $3.50 at your dealers' or by mail.

Radio Set Presented to Veterans' Camp

Mrs. J. Christopher Marks, president of the Theatre Assembly, announced last week that the Assembly has just purchased an elaborate radio outfit for the Veterans' Mountain Camp at Tupper Lake, N. Y. The outfit, which is to be installed immediately, is a complete surprise to the residents of the camp who are confined there through illness.

Features of the Program at WGY

THISTLE DAY, the national holiday of Scotland, will be observed Sunday evening, June 24, with a special service at the State Street Presbyterian Church, Schenectady, N. Y. The entire program will be broadcast by WGY, the Schenectady station of the General Electric Company.

A minstrel performance will be presented by a group of artists from the Pittsfield, Mass., plant of the General Electric Company, Monday evening, June 25.

Tuesday evening the Albany Music Teachers' Association will offer a program of instrumental and vocal numbers. The orchestra will be directed by Mrs. Peter D. Schmidt.

Cyrus Temple Shrine Band of Albany, under the direction of W. Elmore Slack, will entertain from WGY, Thursday night, June 28.

The WGY Players will offer "It Pays to Advertise," a well-known play by Messrs. Megrue and Hackett, on the early program Friday night. At the late concert on the same evening, June 29, a trio of colored women will present a program of southern melodies.

KELLY WAVE SUSTAINING COIL

Eliminates Aerials, Loops and Danger from Lightning

Fit Inside Set

The Kelly Wave Sustaining Coil will work perfectly in any tube set. The coil being sealed under a vacuum, it eliminates STATIC and all interferences.

HYPNOTISM—Controls self and others. Wants gratified. Ten easy methods, $1.10. "MIND-READING" (any distance)—Wonderful, $1.10. SCIENCE INSTITUTE, RW 1014 Belmont, Chicago.

WANTED—Omnigraph in good working condition. Box 435, Hardin, Montana.

MAGNAVOX TYPE R3.—Latest curvex, improved acoustic models, in original sealed factory cartons. List $35. Introductory offer $25. RADIO CENTRAL, Dept. W, Abilene, Kans.

RADIO CRYSTAL SET, guaranteed to get local stations. Silicon crystal, 2½ inch coil. Postpaid with instructions, 90c. Graham, 27 Warren St., New York.

EDISON Elements for making "B" Batteries, 6c per pair; tubes, 2c each. Nickel Wire, Insulators and Cabinets at reasonable prices. TODD ELECTRIC CO., 178 Lafayette St., New York City.

VACUUM TUBES REPAIRED. Reasonable. Send for our price list. Vacuum Electric, Station C, Toledo, Ohio.

FOR SALE—Radio receiving apparatus. Must be sold; half price. Owned by private party, not a dealer. Everything in perfect condition. State what you want, probably I have it. A. D. YOST, Fairmount, W. Va.

ARE YOU IN THE RADIO BUSINESS? If so, drop us a card for price list. If not, let us start you in a good paying business. We furnish everything and have a proposition that meets the needs of 90% of the public. Liberal discounts to agents. Immediate delivery. Write today. THE WILKENDA COMPANY, 300 Fifth Avenue, New York.

FREE CATALOGUE. Ebonite panels, 7x12, 30c.; 23 plate variable condensers, $1.25; American No. 200 Tubes, $3.00; Amplifying, $3.75; W. D. 12 Peanut, $5.75; Sockets, 25c. Stewart's Radio Supply Co., 3124 Cherokee St., St. Louis, Mo.

FOR SALE—Radio Receiver, Navy type, cost $595. Good condition. Dealers invited to call and see. Also 8 genuine "Vario-perm" guaranteed .001 variable condensers. Columbia Print, 1493 Broadway, Room 326, New York City.

$133 WESTINGHOUSE AERIOLA SR. with two stage amplifier complete with tubes and Brandes head set. $98. $125 Amrad No. 3500 four-tube receiver for $98. The Radio Shop, Virginia, Minn.

MAGNAVOX TYPE R3. Latest nationally advertised models, in original sealed factory cartons. List $35. Special introductory offer $25. Radio Central, Dept. W, Abilene, Kansas.

EXCHANGE LETTERS with friends everywhere. Pleasant pastime. Information for stamp. Smith, Box 3125, M. Portland Ore

RECHARGE dry cell batteries. Cost, 5c. Instructions, 15c. J. Brent, 3 Stueben St., Bridgeport, Conn.

FOR SALE—Unwired 3 stage radio 2 audio receiver. Write for information. Andrew Timberlake, Hinton, W. Va.

FOR SALE—Two Myers Choke Coils, 8 Myers tube receptacles, three Cot-o-Coil Radio Transformers, all for $15.00. F. T. Lesser, 85 Lincoln St., Ridgway, Pa.

BROADCASTING OUTFIT using five fifty watt tubes to be sacrificed. Everything complete. Make us an offer. Park City Radio Company, Bowling Green, Ky.

RADIO STORAGE BATTERIES, guaranteed, 50 amp. hr., $8.00. While they last. Write JAMES G. WILSON, Gen. Del., Box 34, Benson Station, Omaha, Nebr.

ELEMENTS OF RADIO TELEPHONY

By WILLIAM C. BALLARD, JR.

Assistant Professor of Electrical Engineering, Cornell University

This is a standard book on radio telephony, the work of a recognized authority.

It is accurate, simple, clear, reliable and strictly up to date.

The man with a technical background who wants to post himself on radio will find this exactly the book for his purpose.

The radio enthusiast will find in it an excellent presentation of fundamental principles and their application.

SENT POSTPAID ON RECEIPT OF PRICE, $1.50, BY

THE COLUMBIA PRINT, 1493 B'way, New York City

Construction of New Type Transatlantic Receiving Sets

By M. B. SLEEPER

Fully Illustrated. Price 75 Cents

IN addition to the listening to ships and broadcasting stations on short wave lengths there is a peculiar fascination about listening to the high-power telegraph stations of England, France, Germany, Russia and Italy as well as those located in the Pacific Ocean and the Oriental Countries. It is much easier to do this than most people imagine. The sending is very slow, a feature of assistance to the beginner in telegraphy. Several types of receiving sets for this task are described. Detectors, amplifiers, oscillators, etc., for long distance reception are also described. Suggestions for the operation of relays by the signals and the reproduction of them on a phonograph are given. In addition there is some valuable data on home made wavemeters for testing and experimenting.

Inter-American Communication Conference Proposed

AN official résumé of the activities of the Fifth International Conference of American States, held at Santiago, Chile, recently, cites the recommendaiton for an Inter-American Electrical Communication Commission and a communications conference as follows:

"Inter-American Electrical Communication: The first part of this resolution recommends to the American States, as an essential part of the public service, the supervision of international electrical communication and also domestic electrical communication insofar as it affects or forms part of the system of international communication. As a part of this resolution provision is made for establishment of an Inter-American Electrical Communications Commission sion to consider the cooperation which may be established between the American states regarding electrical communications, and to prepare a convention which shall establish equitable proportional rates and uniformity of rules governing Inter-American Electrical Communications; this commission to be called at a place and date to be determined by the Governing Board of the Pan American Union. The conclusions of this Commission shall be submitted to the Governing Board of the Pan American Union in order that they may in turn be submitted to the states belonging to the Pan American Union."

Hears by Radio, Though Deaf from Infancy

DEAF from infancy, William T. Walters, aged 31, a resident of Cohoes, N. Y., was recently introduced to the sensation of sound through WGY, the radio broadcasting station of the General Electric Company at Schenectady, N. Y.

Mr. Walters was stricken with brain fever when sixteen months old and specialists said he would never hear. After nearly thirty years of silence, he has heard a human voice and has listened to music.

A friend who is a radio enthusiast read of the pleasure which the partially deaf are deriving from broadcast programs. It occurred to him that Mr. Walters might be able to share in the music of the air. He arranged a test. In a letter to WGY that friend, Myron J. Jackson, describes the test:

"I adjusted the machine to a good clear tone and, after some explanation, put the receivers on the young man's head. He had not been listening more than half a minute when to our surprise and amazement he pointed to an imaginary mustache on his face, meaning a man. At this his mother exclaimed, 'Will can hear!' We waited motionless as Will listened to an address. At the end of the discourse his mother asked him if he had heard and using his right hand he drew a cross on his breast which meant 'honest.' I asked him what the man had been talking about and he pointed to a cigar and blew imaginary smoke from his mouth. The address had been on tobacco."

Another appreciative "listener" who has been deaf a great many years wrote from his home in Hyde Park, N. Y., as follows:

"No one who has not been afflicted with deafness to the extent I have for over thirty years, enough to shut me out from all concerts and lectures and the theatre, can understand the new world radio has opened for them. While some of the smaller stations are not powerful enough for me to hear clearly, the larger ones are, and WGY is best of all. Had I been in the First Methodist Church of Schenectady last Sunday I would not have heard a spoken word and mighty little music, while here in my room I heard everything well enough to follow the whole service, getting nearly every word of the sermon. If you want to confer a blessing on deaf people, let them know what radio will bring into their lives."

Branly, French Scientist, Says Radio Vision Is Possible

ACCORDING to a newspaper dispatch from Paris a wireless eye, capable of vision at great distances, is forecast by the famous French inventor, Edouard Branly, known as the "father of wireless," on the occasion of a scientific jubilee in his honor recently. Branly, who was honored by Government officials, Cabinet Ministers and radio fans throughout France, announced he had succeeded in transmitting by wireless a luminous point, as well as a luminous circle, proving the possibility of seeing by radio at hitherto unimagined distances.

Radio at the Shrine Convention in Washington, D. C.

RADIO, like practically every other activity, took part in entertaining the Shriners at the Nation's Capital last week. Among the features was the reception and amplification by a receiver in the Garden of Allah of a broadcast message from the President read by an aviator in a plane flying over the parade.

A local engineer installed a receiving set and a large loud speaker on the roof of the Albee Building. This apparatus amplified music and other matter picked up from nearby broadcasters.

Part of the Army's night parade exhibit was the miniature radio controlled cart made by the Dayton Air Station, which was operated from an auto some distance in the rear.

NAA put on special programs for local consumption and events scheduled for the convention were broadcast on opening day.

Many visitors were fooled by the loud speakers erected along Pennsylvania Avenue by the local telephone company for amplifying dance music played in an auditorium and relayed by wire to the many horns; it sounded something like radio but was actually wire telephonic transmission from local sources.

Navy Favors Loop Antenna for Receiving

ONE of the good effects of the new broadcasting boom has been to bring to attention the great interference problems which exist, naval experts say. The loop antenna has been brought into great prominence for receiving purposes, as a means available for avoiding interference. Practically unlimited receiving ranges are possible with the loop when sufficient radio frequency amplification is used. One reads frequently of the enormous distances obtained on loops even as small as two feet in diameter. In solving Naval problems, it is very probable that the loop will be of service other than its use for direction finding. It is conceivable that all receiving may be done on loops sometime in the near future as is now done in Washington on the long circuits. Some of the advantages claimed for the loop are: sharp tuning; wide range of frequencies available in a single coil; one tuning adjustment; directive effect; easy portability and replacement; small space occupied, and little re-radiative effect when regeneration is used.

Radio Letters from Latvia

THE Latvian Main Post and Telegraph Administration announces that radio letters to the United States may be filed at all Latvian telegraph offices. The letters will be mailed to Berlin, whence they will be transmitted by wireless to New York, and from there to the addresses by post. The letters must contain text in English, French or German. The charges for radio letters are 35 centimes per word, plus 1 lat (equal to 1 French franc) ground fee per wire.

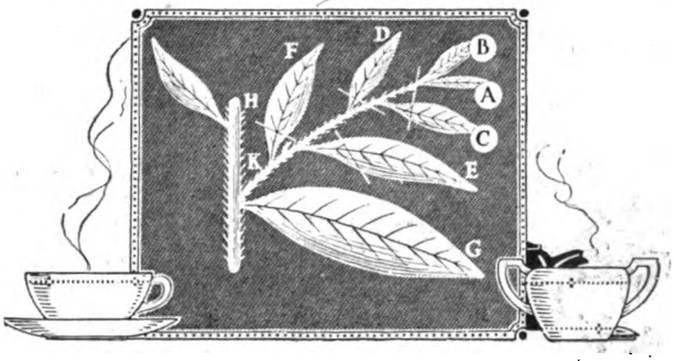
The A.B.C. of Good Tea



THIS diagram shows clearly one reason for the superior flavor, strength and aroma of RIDGWAYS TEA.

The plucking season commences in the early Spring and continues right into the Autumn. At the commencement of the season, the plant sends forth its first tiny shoots. In order to get the very choicest pickings, only those leaves marked "A," "B" and "C" are gathered for Ridgways. These tender, young tip-leaves give to Ridgways Tea that rare quality of flavor which distinguishes the famous Ridgway blends. The leaves marked "D," "E," "F" and "G" are coarser and less flavory and therefore *are never used by Ridgways.*

This carefully guarded Ridgway quality also assures more cups to the pound. When you buy Ridgways Tea you not only get the best tea, but actually more of it than is possible from inferior tea. As an example of rare good tea we suggest that you order Ridgways (GOLD LABEL), the *Genuine* Orange Pekoe.

Be Sure to Insist Upon

Ridgways Genuine Orange Pekoe Tea

A GENEROUS SAMPLE
WILL BE SENT ON REQUEST

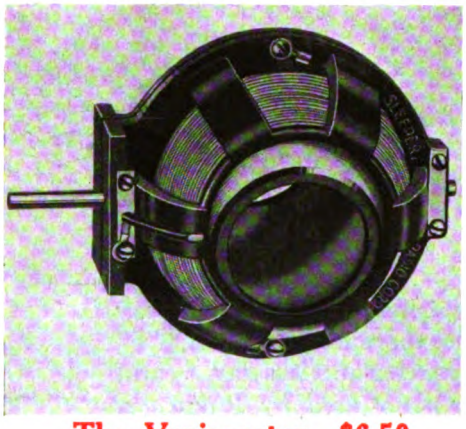
The Fixed Coupler—$4.00



The Variometer—$6.50

The Famous Sleeper Twins

A pair of Sleeper products that has delighted the eye of every radio man who has seen them

THE FIXED COUPLER

The Sleeper Fixed Coupler, built on the same lines as the beautiful Sleeper Variometer, requires no switches, has no taps to be soldered or to break off, has no coupling adjustment, yet it can be substituted for any variocoupler in any circuit where a variocoupler is used.

In addition to its simplicity of design and operation, it gives sharper tuning and louder signals than the variocoupler over a range of 150 to 1,000 meters. You can't imagine what a handsome set can be made with this Fixed Coupler and the Variometers until you use them. Such an outfit is shown in Radio and Model Engineering for June. Send 10c. in stamps and that issue will be mailed to you.

THE VARIOMETER

Endorsed by impartial engineers and testing laboratories as the most efficient molded variometer made in America bar none. The kind that makes the dealer in radio glad he is selling the best and the customer glad years later that he bought the best.

Dealers everywhere write for selling rights—give names of favorite jobbers.

Marconi Experiments With Directive Radio on New Wave

IMPORTANT developments are likely to result from experiments just completed by Senator Marconi and his staff, who arrived at Southampton, England, last week after a two months' cruise. Marconi said to a New York *Times* correspondent on his arrival:

"I have been working on a system of directive wireless telegraphy with highly satisfactory results. The new system effectively eliminates atmospheric disturbances. Wireless is still in its infancy."

Marconi has been developing his system of sending direct messages by wireless for many months. On his last cruise he has been experimenting on localization. Whereas wireless messages hitherto have been broadcast and could be picked up by other suitable instruments besides that of the recipient, with the new system it will be possible to send messages by wireless to one place only.

Senator Marconi, in a further interview on the results of his experimental cruise, said they constituted a great progressive step in wireless telegraphy.

"We have transmitted a message up to the distance of 2,500 miles not only with a very much smaller amount of power and energy, but also faster and more cheaply than with the ordinary system of long-distance wireless," he said.

"There is a great increase in efficiency and the cost is much reduced where this system is adopted. It will mean that a power station for long-distance work can be erected at much less cost. I have telegraphed on this system from the Cape Verde Islands, off the African coast, to Marconi House, and I wanted to try telegraphing from Brazil, but time prevented it.

"To send this message clearly and more rapidly over those 2,500 miles took less power than a message from London to Paris by ordinary methods. In fact, it was only a small fraction of the power required. It is done by the utilization of waves that have not been used before, and the production of them makes for efficiency."

During this cruise the yacht "Electra," on which the experiments were conducted, touched at Seville, Gibraltar, Teneriffe, Tangier, Capablanca and Madeira. Thence the yacht went to St. Vincent, Cape Verde Islands. Marconi purposes to go on another experimental trip in a few weeks' time and later to try his new system of long-distance wireless from off the coast of America.

Civil Service Examination to Fill Junior Positions

THE United States Civil Service Commission announces an open competitive examination for junior engineer, junior physicist and junior technologist.

The examinations will be held throughout the country on September 5. They are to fill vacancies in the Bureau of Standards, Department of Commerce, at entrance salaries ranging from $1,200 to $1,500 a year, plus the increase of $20 a month, and vacancies in positions requiring similar qualifications.

Examinations will be given in the following optional subjects: For junior engineer, ceramic engineering, civil engineering, chemical engineering, electrical engineering, engineering of materials, mechanical engineering and radio engineering; for junior physicist, electricity, heat, mechanics, optics, physical metallurgy and radio; for junior technologist, general technology, leather technology, oil technology, paper technology, rubber technology and textile technology.

The work of the Bureau of Standards includes many branches of physics, chemistry and engineering, such as mechanics, heat, optics, electricity, sound, metrology, metallurgy, radio, electronics, etc., and offers valuable experience in these professions, combining, as it does, theoretical, experimental and practical work.

Full information and application blanks may be obtained from the United States Civil Service Commission, Washington, D. C., or the Secretary of the Board of U. S. Civil Service Examiners at the post office or custom house in any city.

"Leviathan" Has Duplex Radio Equipment of Great Power

By Charles Raymond

WHEN the reconditioned "Leviathan," the giant greyhound of the seven seas put out of Boston on a five-day trial trip it boasted the finest radio apparatus that graces any ship afloat. It is the first vessel to be equipped with radio apparatus that will allow simultaneous reception and transmission over a number of wave lengths.

This was accomplished after many months of experimentation by the engineers of the Radio Corporation of America, who equipped and will operate the station. In external appearances the transmitting apparatus greatly resembles the conventional radiophone apparatus used by broadcasting stations of the present date. But here the similarity ends.

By a special arrangement of channels and controls it will be possible for anyone on the ship to get into communication with any telephone receiving and transmitting station on land, and talk and listen with no more trouble than is experienced over a land wire. There will be no switching from listening to transmitting, or vice versa, and it is planned to establish a system of stations on land whereby the regular telephone lines can be used and by means of relays the people in the farthest reaches of the United States can be put into instant communication with anyone aboard the ship.

A special antennae system is installed, the major one of which is 600 feet long and over 200 feet above the water line. Other antennae are erected and can be switched to any of the apparatus used.

(C. Underwood & Underwood)

Powerful radio transmitters and receivers, allowing perfect duplex operation, installed on the S. S. "Leviathan."

Special tube transmitters of higher power than ever used on board ship before are installed, and communication can be carried on over a radius of approximately 4,000 miles by means of CW, ICW, and phone. The receiver is specially designed and is the most powerful yet made. It is said to have a consistant range of 6,000 miles.

This is the first time that any ship has had radio equipment of such tremendous power and scope.

Digitized by Google

Pointers on Radio Trouble Diagnosis

By Kenneth Malcolm, A.I.R.E.

THE radio game is certainly discouraging to those who have had perpetual ill luck with their instruments. However, there is a cause for every little squeak and every click, and a careful search will bring all the troubles to the light where you can set about to remedy them. The following description of symptoms covers most of the ailments that are to be found in amateur receiving sets of the more conventional types.

First of all, a mention of the quality of apparatus will not be amiss; this factor cannot be emphasized too strongly. Whereas a set using a given circuit and high quality parts will give extremely fine results, a set using the identical circuit but with inferior parts may not work at all—so great is the difference. Just what constitutes quality in receiving apparatus? Well, let us look at the various instruments and see.

The coils of variometers, variocouplers and other such instruments should be wound on some rigid, non-hygroscopic form; that is, if a tube is used, it should be of impregnated cardboard, hard rubber, or one of the phenol condensation products, such as bakelite, formica or condensite. Wood parts should be thoroughly seasoned and impregnated to prevent absorption of moisture. All lead wires should invariably be soldered. The wire on coils should preferably be insulated with cotton or silk and uncolored.

All insulating parts should be of hard fibre, hard rubber, or one of the phenol products mentioned. Wood is not a good insulator unless perfectly dry and well seasoned. Metal parts should be of copper, brass, aluminum or some material that is non-magnetic.

Condensers are very important instruments and should be chosen carefully. Be sure that the plates are securely mounted and rigid enough to keep from bending, thus either short-circuiting or changing the capacity. Grid condensers, and other small fixed condensers, should preferably have a dielectric of mica. If paper is used, it should be so compressed and impregnated that it is impossible for the foil and the paper to change their relationship to each other. It is best to throw out a condenser whose capacity can be changed by squeezing.

The most common noise in a receiving set is a kind of clicking or grating that may sometimes be mistaken for static. This can be due to only one thing, the microphonic action set up by a loose connection, or an imperfect contact. Go over all your wiring and see that all connections are soldered. Look to your batteries and see that all wires are tight. Possibly a connection is defective on one of your instruments. If the concerts come in intermittently and go out the same way, without any apparent cause, the loose connection is an actuality. Take a peek at your aerial and make sure that it is not blown against some grounded conductor.

If signals come in fine on the detector tube, and not so good on the amplifier, inspect the jacks and the transformers. Many times the jack springs become weak and cause an imperfect connection. You can tell if there is an open circuit in the transformer by connecting it in series with a phone and a dry cell—one coil at a time. If you can get a click the coil is perfect. How are your B batteries? Are you employing the proper voltage for the tube you are using? With certain tubes it is just as much a sin to use too great a voltage as it is to use too little.

Squeals and howls are caused by a number of things, both natural and unnatural. If you are using a regenerative set, the tube would naturally squeal as it passes on either side of the incoming wave mark. If it squeals otherwise, your plate voltage is too high, your filament voltage too high, the regenerative coupling is too close, or else your grid condenser or grid leak is of improper value—possibly it is one of that squeezable changeable kind. Possibly your grid circuit leads run too near to the connections of the plate circuit. If you are using several stages of amplification it is possible that your transformers are too close together; shielding them, separating them, or tuning them at right angles to each other will help this.

If your set howls when you bring your hand near it or take it away, the best thing to do is to extend the shafts and move the instruments farther back in the cabinet, or shield the set with a metal plate fastened on the back of the panel; this latter should be connected to the ground post.

If your set works perfectly for local reception, but makes all kinds of noises when getting distant stations, your trouble is clearly defined. It simply means that you have to use too much regeneration in order to bring in the distant station. Regeneration can be carried only to a certain point; after that the waves become distorted and unintelligible. If it is necessary that you get the station in question perfectly, the regeneration must be cut down, and a stage or two of radio-frequency amplification added.

The tuning may be made sharper, especially in single circuit sets, by shortening the aerial to about say 80 feet, and adding a loading coil to make up the difference.

Those who are bothered excessively with static can move their aerial indoors to advantage, or a temporary aerial can be strung up around the picture molding. If you have a sensitive set, a loop aerial would make an excellent static eliminator; and would also give an added selectivity. Static can be reduced in sets having a loose coupler, or a variometer, by reducing the coupling. The static will be reduced greatly out of proportion to the reduction of signal intensity.

Coils may be tested for open circuits by the method mentioned for use with transformers. Condensers may be tested in the same manner, except that a click in the phone in this case would mean a short-circuited condenser, whereas no sound at all would indicate that it was perfect.

The tubes themselves are many times at fault, and the best thing to do is to test them on some other person's set. Shifting tubes will sometimes help. One particular amplifier tube might work better in the first stage than in the second stage; a detector tube might be better as an amplifier; and vice versa. Soft tubes make poor amplifiers, and all hard tubes cannot be successfully used as detectors.

How are your phone cords? Many times these become broken under the heavy outer insulation and pass detection. Test them, or try a new set of cords. Such a condition would prevent reception entirely or would produce the scratchy noises that have been attributed to loose connections.

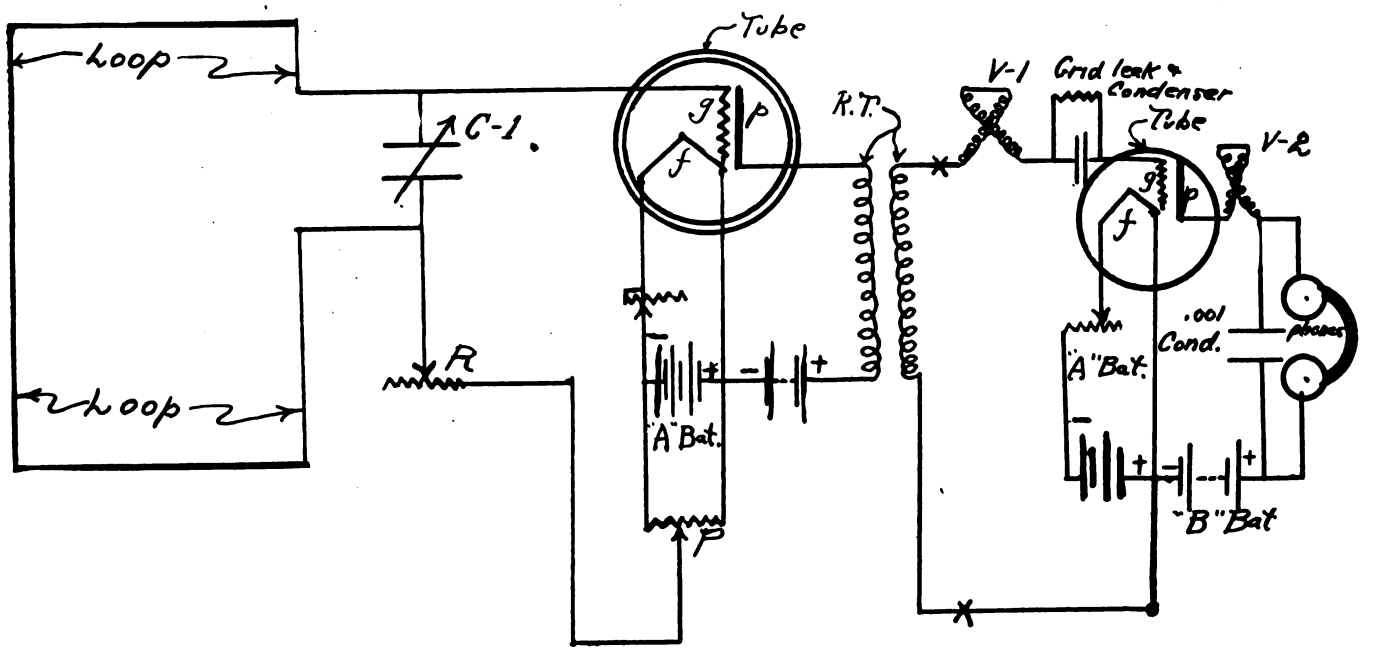
Radio-Frequency and Regeneration with a Loop Set

By C. White, Consulting Engineer

RADIO-FREQUENCY amplification and regeneration have always been considered an ideal combination but certain difficulties have always been present and rendered it next to impossible to accomplish commercially. One of the most potent troubles has been the inability to obtain stability; in other words one or all of the tubes in the circuit would start oscillating and it would be next to impossible to stop it. One solution has been to keep the source of power supply for each of the radio-frequency tubes and the other tubes separate. It is quite obvious that such an arrangement would not lend itself to portability or economy, since a separate set of "A" and "B" batteries would become necessary for the radio-frequency tubes, and the detector and audio-frequency amplifiers. The advent of the new UV199 tubes makes it readily possible to supply a separate "A" and "B" group for each tube or group of tubes without adding materially to weight or cost. By using the new tubes you can design and build this ultra efficient receiver and obtain results with a loop aerial that will rival in volume the best obtainable results from a good outside aerial, and the quality will be many times superior, especially since the loop collects only a very small amount of static because it is operated only a few feet from the ground and takes up so little space. The directional feature of the loop is very advantageous in cutting down interference from spark stations.

The loop not only acts as a collector of the signal energy but also acts as a part of the main tuning element. No effort should be spared to construct the loop with great care. The wire should be stranded or plaited copper ribbon and the loop wire or the lead in wires from the loop should not be allowed to rest on anything except some reliable insulating material. The loop should measure about three feet per side and should have ten turns in all. In order to provide a means of tuning the filament-grid circuit of the first tube the condenser C-1, in the sketch herewith, is employed. C-1 is an air variable having 23 plates in all and a reliable form of vernier control. The cabinet holding the set should be partitioned off at the points marked x x on the diagram. This partition should be coated with copper foil in the same manner as the walls of the cabinet and panel. You may be able to get away with very little shielding with an ordinary regenerative receiver but when radio-frequency is used with regeneration shielding must be carefully carried out in order to prevent interstage coupling.



Schematic diagram depicting how a single stage of radio-frequency can be combined with a regenerative set to operate on a loop. Full directions are given in the accompanying description for the construction of this set.

Every possible precaution is taken against oscillation on the part of the radio-frequency tube. The first provision is the employment of the potentiometer P whose resistance should be around 400 ohms. The resistance R is another such precaution. The resistance R should be of the 400 ohm type, but in order to keep down noise during adjustment it is better to get a resistance of the smooth varying type such as the carbon pile potentiometers.

The radio market for reliable radio-frequency transformers has certainly improved within the last six months. It is now easy to purchase good radio-frequency transformers and you should take care to see that you get one of the better types that are now available. The connection of this transformer is indicated by the letters R.T. on the schematic diagram. The variometers V-1 and V-2 are ordinary standard variometers for short wave work. Finer tuning adjustment and the amount of regeneration is fully controlled through these two variometers. Owing to the fact that radio-frequency amplification is added to the benefits of smooth regeneration it is little wonder

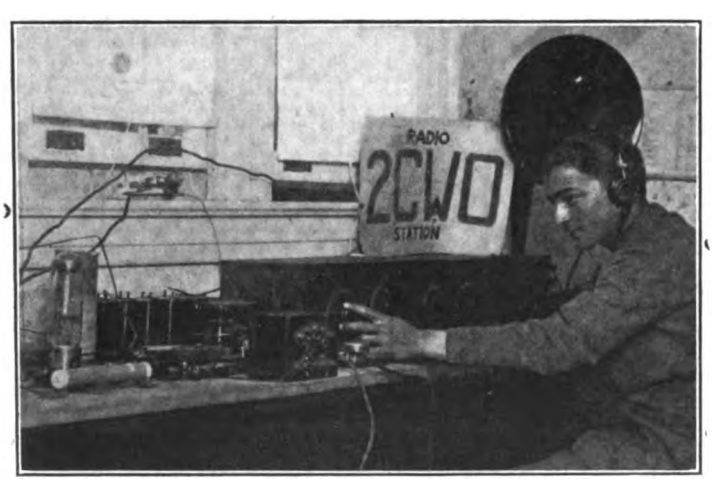
Scrambling the Conversation Insures Radio Telephone Privacy

THE radio telephone link between Los Angeles and Catalina Island, 30 miles off the coast of California, has set a new record in the history of communication. It is the scene of the first trial on a commercial basis of a radio telephone system insuring privacy to its users. The radio telephone apparatus which has heretofore established connection with the mainland is now replaced by a new radio development of the Bell System engineers which may be called a privacy system for the radio telephone. The new apparatus prevents any of the receiving sets commonly in use picking up the messages transmitted by this system and converting them into understandable speech.

The wireless "talk bridge" which has given telephone service across the 30 mile gap of water separating Catalina from the California coast is unique in many respects. It was designed and installed in 1920 to give two-way talk between the mainland and an island 30 miles at sea, and has proved in on a commercial basis, giving satisfactory transmission day and night throughout the year.

Now again the Catalina Island radio link is distinguished as the first to be equipped with the wireless telephone privacy system recently developed by the engineers of the Bell System.



(C. Photonews, N. Y.)

Edward C. Tassi, a Brooklyn, N. Y., amateur and his radio station. He uses a single 50-watt tube transmitter employing the Hartley circuit, and has been heard great distances.

Heretofore talks over the Catalina Island link while clear and understandable to those using the service, have also been picked up by amateur radio receiving stations in the neighborhood, so that the privacy of the usual telephone conversation was lacking. Any radio receiving station in that part of the country, if it happened to be tuned to the right wave length, might get fragments of the talk with Catalina Island, which would be of no interest to the radio listener. Of course, the talket could not tell how far afield his words might accidentally go.

The privacy system was designed by the American Telephone and Telegraph Company to largely remedy this situation. It is not claimed that the new system is absolutely secret, but at least privacy has been obtained, so that no one will inadvertently overhear the conversations which are transmitted by this system.

The new radio equipment which has been installed both on the Island and the mainland will handle telephone messages in such a way that they will be unintelligible to all ordinary radio receivers. In a word, the new sets, before putting the messages "on the air" will distort or scramble them, and no receiving set which is not specially designed or manipulated to unscramble them can obtain anything intelligible.

While anyone familiar with this system, and possibly an ingenious person not familiar with it, might devise a set which could listen to the system, such a set would be much more complicated than the ordinary set, and the added complication would be of no value except for picking up transmission over this system. It is, therefore, not likely that many people will undertake this work.

Such a privacy system may be compared to a lock and key. A person relies upon a lock to secure his house and other property and is not much troubled by the possibility of a thief breaking in to steal. However, this is always a possibility. The privacy system presents an analogous case. For all practical cases it insures the requisite privacy to a radio telephone conversation but it does not make impossible the designing of a special set, near enough like the receiving sets used in the system itself, to transform the messages into more or less intelligible form.

(Concluded from preceding page)

that such good results are so easily obtainable. But you will have to be more particular with your little constructional details. All connecting wires should be kept as short as possible and at the same time they should be well insulated. Do not allow two different wires to rest against the copper foil shielding. If this is done serious capacity leakage will occur if the wires happen to be at a difference of radio-frequency potential.

While this outfit is not so compact as some other types of summer receivers still I think that for reliability of results it is worth the increased bulk. Of course, if you prefer loud speaker operation one or two stages of audio-frequency amplification ought to be employed. If this is done it will not be absolutely necessary to use a separate set of "A" and "B" batteries for the amplifier, since the same "A" and "B" of the detector will amply serve. But it will be advisable to use a separate small flashlight type of "A" battery for each tube. Of course, if the No. 6 type of dry cell is used for the detector "A" it will be large enough to supply filament current to the amplifier tubes as well. For average usage 45 volts on the plate of the radio-frequency tube, about 22 volts on the detector and 45 on the audio-frequency tubes, if audio-frequency is employed, will be about the right "B" potentials. To enhance portability the small style of "B" batteries can be used. The set could have been designed to use choke coils and telephone size condensers, but it is cheaper and more reliable to employ separate "A" and "B" batteries. The UV199 tubes, as I have said before, are the ideal tubes for this set because they draw little current for filament use and an ordinary set of two flashlight cells is enough to supply current for quite an extended period.

"Radio Movies Are Here"—Jenkins

By Washington R. Service

THE near future will see the perfection of radio movies; essentially, they are here to-day. Every "listener-in," with the aid of a special apparatus, contained in a box about a foot square, and a small curtain, will be able to see as well as hear over the versatile radio, according to C. Francis Jenkins of Washington, D. C.

Last week Professor Jenkins, who has previously demonstrated the transmission of still pictures by radio, showed on a screen in his laboratory the movements of his hand and other objects held in front of his radio transmitting apparatus in another room. The apparatus used in transmitting still pictures was employed in the last experiment, but a new "lens-faced prismatic ring" was introduced to show a rapid succession of pictures depicting movement.

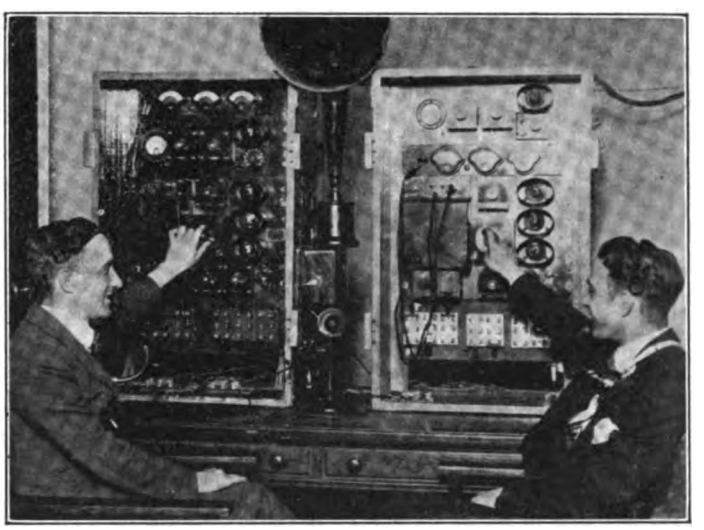
Perfection of the moving picture radio transmitting set now awaits only the manufacture of a new and more powerful electric lamp of the "corona-glow" type. In the recent demonstration a temporary lamp was made by the inventor but it is not strong enough to transmit large pictures. The question of rapidity is solved, Professor Jenkins says, as he has already sent pictures at twice the standard movie speed. What he needs is a better and stronger lamp which will stand up when the signal strength is increased about 3,000 times, as is necessary in sending pictures in motion.

Not only actual pictures of moving bodies can be transmitted, by pointing the machine at them, but films can be broadcast, he claims, as shown on screens in theatres or homes where proper receiving and reproducing apparatus and a screen are available. When the power of the light is raised the size of the picture can be increased, it was explained.

Radio experts of the Navy, who saw the first demonstration between two rooms of Professor Jenkins' laboratory on Connecticut Avenue, say that the invention is adaptable in military operations as well as in commercial fields. They point out that a transmitter used in an airplane over the enemy fleet or trenches, would give officers far in the rear an actual view of the fall of shells and all front-line activities. In the commercial field, with some adaptations, moving picture distributors might transmit their films to subscribers via radio instead of by express, saving time and the making of many copies.

With the completion of his new lamp, probably not sooner than several weeks, Professor Jenkins promises to give a long-distance demonstration, transmitting pictures of objects in motion and perhaps films, between Washington and probably Philadelphia.

Four Large Broadcasters Operate Simultaneously



(C. Photonews, N. Y.)

For the first time in history four radio stations broadcast the same program, although separated by many miles. The annual convention of the National Electric Light Association at Carnegie Hall, New York City, was broadcast through Stations WEAF, KDKA, KYW and WGY, first relaying the speech over land lines by means of the double set of speech amplifiers shown here.

Radio Frequency Indicator for Broadcasting

AT the recent Second National Radio Conference held in Washington, it was resolved:

"That every broadcasting station should be equipped with apparatus such as a tuned circuit coupled to the antenna and containing an indicating instrument or the equivalent for the purpose of maintaining the operating wave frequency within two kilocycles of the assigned wave frequency."

The Bureau of Standards has designed a preliminary model of a radio frequency indicator to meet the above need and has prepared specifications covering its construction. These specifications may be had by any broadcasting station upon request.

The instrument consists essentially of a 72-turn space-wound coil on a 3¾-inch tube, an air condenser, and a sensitive thermo-galvanometer. These three elements are connected in series. The condenser, which is of the variable type, is provided with a locking device so that it may be locked and soldered into position after the instrument has been adjusted to indicate the required frequency. This instrument may be set to indicate any radio-frequency in the range from 1350 kilocycles (222 meters) to 550 kilocycles (545 meters).

If any instrument is constructed according to the specifications and sent to the Bureau of Standards Radio Laboratory, by a licensed broadcasting station, it will be adjusted for a nominal fee to operate at the frequency of the station.

Who Is Your Favorite Radio Entertainer?

THE editor of RADIO WORLD is interested in finding out just what kind of entertainment and just which entertainers are most appreciated by listeners throughout the country.

We should be glad to have you, as a RADIO WORLD reader, write us and let us know, in a short letter running from twenty-five to fifty words, the kind of entertainment you like best and the name of the man or woman who has most appealed to you as a radio entertainer.

Address Editor, RADIO WORLD, 1493 Broadway, New York City.

Hints and Tips for the Radiofan

Shop Kinks, Short Cuts and Easy Rules of Thumb for Amateurs

UNDER this heading RADIO WORLD will publish from time to time helpful hints that the average fan is not aware of and that will help him to get the most out of the construction and operation of his set. Such things as shop hints and little warnings of what not to do and what to do in the use and care of a set will be told in such a manner as to be of real practical value.

Phones—How To Take Care of Them and Use Them Properly.

By C. E. Brigham,

Radio Engineer, C. Brandes, Inc., New York City

Telephone receiver apparatus is one of the most delicate of the sensitive instruments used in or around a radio set. Therefore, a certain extra amount of care should be taken of them if they are to render the exacting service that they should and do it in the proper manner.

(C. Underwood & Underwood)

A summer's day at Rye Beach, N. Y. First a sea bath and then a rest in the canoe while the radio concert comes in. Almost ideal, what?

The average amateur would do well to memorize a few good rules that will prolong the life of the phones and help them to give him perfect service. Some of these are:

1. Don't try to find out what is inside of your receivers. By doing so you spoil the tone quality by disturbing the setting and also destroy the perfect tone matching of the two receivers.

2. Don's drop your receivers from a height of greater than three feet. To do so you will cause the magnets to lose their magnetism and render the phones useless. It has been proven that a good phone should stand a jar occasioned by a drop of three feet without any great harm. But don't try it just to prove it—take it for granted and take care.

3. Don't connect up your telephone receivers at random. There is a correct manner in which receivers should be connected when used with a set. This is especially true of a vacuum tube receiver. Make sure of the polarity of your cords when hooking up your phones in a plug. Trace your connections.

4. Don't blame the headset for every trouble which occurs. Check up the rest of your set.

5. Receivers should not be re-magnetized unless the proper equipment for doing so is at hand. You cannot do this by connecting them across a 110 volt current. If you do so you will burn out the wires which are finer than a human hair.

6. A headset should not be judged by its direct current resistance, but by its alternating current opposition which is known as its "impedance."

7. It is a good plan to have a convenient hook to hang your receivers on. This prevents any chance of them being dragged or pushed off the table onto the floor, and makes a much neater appearance.

8. If you think your receivers are losing sensitivity send them to the manufacturer and he will fix them. Don't attempt it yourself—it is the work of an expert.

9. Always keep your phone cord dry. Do not let acid come in contact with them.

10. An ordinary receiver is not a loud speaking phone and should not be used as such. Loud speakers are specially made to stand heavy currents and it is poor policy to use regular head phones in conjunction with a power amplifier.

11. Phones are poor battery testers and batteries are poor for phone testers. Do not use head phones where there is current flowing. The current normally flowing in the plate and phone circuit is of minute quality and the fact that you are using 22½ or 45 volts in the circuit does not mean that phones will stand that direct current through them. They will not.

12. The correct manner to connect up numerous pairs of phones is known by few people. If you are using

A—2 pair—they should be connected in series.

B—3 pair—they should be connected in series.

C—4 pair—they should be connected in series—parallel groups of two each. Two in series and the lot in parallel.

D—6 pair—they should be connected in series-parallel—three groups of two each. Two in series and the three groups in parallel.

Shop Kinks for the Amateur Worker

When turning down or dressing a rough casting and it is not desired to use your good tools, try using an old file sharpened to a flat or sharp edge as needed by the class of work.

Bakelite will sometimes swell when worked fast. Tools used for drilling or cutting bakelite should not be forced or their temper will be lost. You may be in a particular hurry to drill a piece of bakelite, but you will lose a good drill, or saw if you force it. Take it easy, and stop when it shows signs of heating.

Good work cannot be accomplished with dull tools. It only takes a minute to keep them sharp with the aid of an oil stone, or emery wheel, and you can do much neater work.

If your drills go dull on you don't try to sharpen them unless you understand how. A good drill has a certain angle for each type of work, and if you don't understand it, you run a chance of spoiling your drill and the work also. Take it to some one in the shop who knows.

A handy marker for use when drilling and sawing a polished panel can be made from an old nail punch sharpened to a point.

Pitfalls of the Radio Investigator and Inventor

By Everett N. Curtis

(*Concluded from last week's* RADIO WORLD)

[*Everett N. Curtis, the author of this article, is the lecturer on patent and trade-mark law at Columbia University and is a patent solicitor in active practice in New York City. He is the author of Curtis' "Manual of the Sherman Law" and a number of monographs. He was graduated from the Massachusetts Institute of Technology in* 1898 *and from the Boston University Law School in* 1900.—*Editor,* RADIO WORLD.]

ANOTHER matter to be considered by the inventor is the importance of preserving the dates of his invention. If he obtains a patent and thereafter brings a suit, it may be advisable to show that he conceived his invention and reduced to practice before the person who is claimed to be a prior inventor, or prior user, or author of a prior publication. Such proof may also be important should he be thrown into interference in the Patent Office during the prosecution of his application. No inventor's mere say so, uncorroborated by other evidence, will be sufficient to establish the date of invention. There must be evidence of disclosure to others, drawings or writings, or the embodiment of the invention in some perceptible form. Memorandum books with dated and witnessed sketches and descriptions are often used to prove the date of conception. All inventors should have such books or memorandum sheet, and should carefully preserve the same. As soon as the creative thought occurs to the inventor, he should record the same in his memorandum book, and if possible should fully illustrate the same with sketches. When he has done this, he should have the same witnessed and signed by one or more witnesses. Letters written to some member of the inventor's family or to a friend, making the same disclosure, are also good evidence, particularly where the envelope showing the cancellation date of the Post Office is preserved. Probably the best evidence outside of a reduction to practice is an affidavit with attached sketches before a notary public, with his seal attached. But even the establishment of the first date of invention may come to naught unless the inventor is shown thereafter to be diligent in reducing his invention to practice. The inventor should, therefore, be prompt in trying out his invention in some practicable form; his work must be promptly finished physically as well as mentally. If he waits too long between conception and reduction to practice some other inventor who may independently conceive the invention subsequent to his date of invention but who first reduces to practice may be held to be entitled to the patent because of the want of diligence of the earlier inventor. Reduction to practice may be accomplished in two ways. *First*, by carrying out a process on a commercial or practicable scale, by constructing and operating a practicable machine, or by producing an article of manufacture, or composition of matter, or *Second*, by filing an application for patent, which operates as a constructive reduction to practice. In any event the inventor, should take care, in so far as possible to make his disclosures to persons of intelligence, since otherwise he may jeopardize his rights if he depends upon evidence of witnesses who do not rightly comprehend the invention or its purposes, and cannot therefore clearly testify as to what the disclosure really was. Memoranda, sketches, and letters if once established speak for themselves, it is true, but corroborating witnesses if not intelligent may make difficult even the establishment of such written evidence.

Another matter sometimes overlooked by the inventor is the necessity of making a full disclosure in his application for patent. If the patent attorney who draws the application has not all of the facts as the inventor knows them, such inventor should not complain if he finds his invention is not fully covered and protected. If possible, the inventor should supply his attorney with the fullest possible written description of his invention, together with working or intelligible drawings. If the inventor must supply his description verbally, let it be very full and complete. Furthermore, the inventor should insist that he be permitted to take home and consider the specification and claims after the same have been prepared by this attorney, and after he receives such specification he should read the same with the utmost care to be sure nothing has been left out. After the application has once been filed, while the full opportunity is otherwise afforded for amendment, the Examiner will not permit *new matter* to be added. The inventor should also study the claims, which are the measure of the patent, and carefully bear in mind that everything which is not claimed is dedicated to the public. He should also consider that the more carefully prepared the specification and claims of the application, the more valuable will be the patent when issued. If he hurries his patent attorney, or in his anxiety to get a patent at the least possible expense, employs inferior talent, he must not be surprised if his patent when issued is of such narrow scope as to be of little or no value. If, therefore, the inventor finds himself in a position where by reason of lack of means, he is unable to employ a solicitor of standing and experience, he should endeavor to seek out and interest some person with capital in his invention. It is better by far to have a half interest in a valuable patent with broad claims than the whole interest in a patent with claims so narrowed that they are limited to the precise device shown and can be easily avoided without penalty.

The inventor should also consider the two years statutory bars of the statute, and take care not to use his invention commercially or publicly for two years before applying for a patent. A public publication or use two years prior to an application completely bars an inventor to the right to a patent. If therefore any person, including the inventor, has de-

(*Continued on next page*)

Digitized by Google

(*Concluded from preceding page*)

scribed such invention in a printed publication or has used the invention for more than the two years prior to his application the inventor forfeits his rights unless he can show such public use was entirely his own and was experimental in character. An example of such experimental use is that of an invention for a city pavement, where it might be necessary in order to test the same experimentally, to employ more than the two years public use. Courts, however, are prone to look askance at the suggestion of experimental use in reply to the defense of public use, so that it is wise to avoid experimental use by the inventor if possible.

Where an employee invents, even though the invention is made during hours of employment, and the employer pays for the prosecution of the application, all that the employer will obtain in the absence of any express agreement is a shop right or at the most an implied license. The right to the patent still remains in the employee. Where there is an express agreement that the employee will assign to his employer all his inventions relating to the employer's business during the period of his employment, the courts will enforce such agreement and compel the inventor to assign. Agreements, however, of this character are strictly construed, and unless the word assign or the equivalent is used, the tendency of the courts is to give the employer only a shop right in the invention. If the agreement were not restricted to a particular class of inventions, or to the business of the employer, and required the inventor to assign to his employer all his inventions of any nature whatsoever, the court would hold such an agreement to be in restraint of trade and would refuse to enforce it.

The patent law requires all assignments of patents as against a subsequent purchaser or mortgagee for a valuable consideration without notice, to be recorded at the Patent Office within three months from the date of the assignment or prior to such subsequent purchase or mortgage. Except, however, as against such purchaser or mortgagee, recording is not necessary to the validity of the assignment or chain of title. This clause is not very important as to the inventor, except as he may desire to protect the interests of assignees, or except perhaps as he himself may acquire patent interests. Any person purchasing a patent should cause a search of the title to be made at the Patent Office at Washington in order to make sure that such title is clear, and should in general take the same precautions as if he were taking title to a parcel of real estate.

By joint inventors is meant those inventors who together create a single invention. They are entitled to a joint patent, but neither of them can obtain a separate patent for the invention. If they desire they may file separate or joint applications, but only one patent will issue. The fact that one person furnishes the capital and another makes the invention does not entitle them to make an application as joint inventors, but in such case they may become joint patentees upon the inventor assigning an undivided interest to his colleague. Independent inventors of distinct and independent improvements on the same machine cannot obtain a joint patent for their separate inventions. In such case a separate application should be filed for each inventor. Since it is but rarely it can affirmatively be shown that two or more persons have joined in the creation of the invention, very few applications for a joint invention are filed. Great care should be exercised by the inventor where he supposes he is a joint inventor. In many cases it will be found after carefully sifting the facts there is in reality but one inventor, and if such inventor is so careless as to permit another person to be joined with him as joint inventor, the results may be very serious in case of litigation. After the patent for a joint invention has been issued, if it develops that the invention is not in fact joint, the patent will be declared to be void.

In some instances it may be determined that particularly where a process is concerned that such process will be held secret. In case the inventor determines upon such course, he should carefully bear in mind that once he has determined to keep his invention secret, while availing himself of the results commercially, he may if such secret use is long continued, lose his rights to a patent. In some cases the inventor after using his secret process for a number of years has become alarmed lest such process through the unfaithfulness of an employee might be divulged to the public and has made application for and has received a patent for such process. Where such facts, however, have appeared to the court, it has been held, in the case of a concealment for the purpose of profit over a long period of years, the patent will be held to be void because of constructive abandonment or forfeiture of the right of an inventor to a patent.

So far as concerns foreign countries, the inventor should bear in mind that once the invention is divulged to the public, either in the form of a patent or other printed publication, such publication will become a bar to the issuance of a patent. This applies particularly to foreign countries, there being an exception relative to U. S. patents in the case of the inventor himself who is not debarred from receiving a patent for his invention in this country by reason of its having been first patented by him abroad, unless the application for the said patent was filed more than twelve months prior to the filing of the application in this country. The proper course to pursue in the ordinary case is after notice of allowance is received by the inventor in this country, to utilize the six months in which he is to pay his final fee for the filing of such applications in foreign countries as he may desire. In this country a patent does not go to issue, that is become published, until the final fee has been paid, and since the inventor has six months for such payment he has ample time before paying such fee to file his applications abroad.

Another important matter to be considered is that of constructive abandonment of an invention. This occurs where the inventor by reason of indifference or otherwise permits others to use his invention without objection over a substantial period. Where the invention has been thus abandoned the right of a patent is gone on the theory that where a gift is once made to the public it can never be taken back. Sometimes where an inventor has ceased experimenting upon a particular device which has proved defective for the purposes for which it was designed, such situation gives rise to the presumption of an abandoned experiment. Once the inventor has exercised his creative faculty and has conceived an invention it is accordingly incumbent upon him to proceed diligently in perfecting his invention and applying for a patent, since otherwise, his lack of diligence or slothfulness may be construed as an abandonment, in which case his right to a patent is entirely gone.

Such are the main pitfalls to be encountered by the ordinary inventor in this country, most of which may be avoided through the use of ordinary care on the part of the inventor. At all times the inventor should bear in mind the maxim of the equity courts, in which most patent cases for infringement are tried, which is that equity aids the vigilant, not those who slumber upon their rights.

RADIO PRIMER

For the New Army of Radio Beginners

By Lynn Brooks

AUDIO-FREQUENCY AMPLIFICATION: In a receiving circuit consisting of the regulation tuning circuit and rectifier or detector, no more current can be made to flow through the phone circuit than is originally found in the circuit itself. Self amplification is possible through regeneraton as previously stated, but even this method has its limits. To make the received signals louder means have to be employed to step up the current and for this purpose amplifying circuits are employed.

A properly designed audio-frequency amplifying circuit bears a great resemblance to a tuned detector circuit as can be noted by comparing the two. The main difference in the two is that a transformer is used and there is no condenser in the grid circuit, as the signals are of audio-frequency (15,000 cycles or lower) and they are pulsating direct current and do not have to be rectified. The amplifying transformers used bear a great resemblance to the ordinary step-up transformers used in low frequency work. An iron or steel core is wound with a great number of turns of very fine wire. Over this is wound another coil of wire, generally of a smaller size wire, and with 3½ to 10 times the amount of wire of the first coil. Upon the ratio of one winding to another depends the ratio of the transformer.

This transformer is inserted in the place of the phones, the primary or smaller winding taking the place of the phone windings. The secondary is connected in the grid circuit of the second tube. When a current is flowing in the detector circuit an induced current is caused to flow in the secondary winding. As this winding is connected in the grid circuit, any current flowing in it will be correspondingly heard in the phone circuit of the second or amplifying tube. This current, due to the fact that the transformer steps up the minute currents allows a very weak current in the first tube to be heard, with a corresponding increase in strength in the second tube.

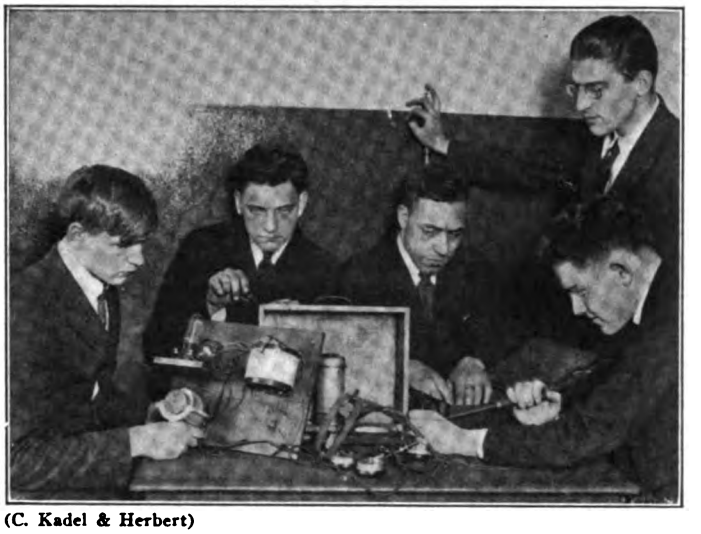
It is to be understood however that audio-frequency amplification will not allow the amplification of signals which cannot be heard with the detector alone.

When handling audio-frequency amplification circuits, certain precautions must be observed. Due to the fact that there is an electromagnetic field of considerable strength generated around a transformer, it is necessary to see that the transformer is not placed in such a manner that the field will interfere with the other parts of the circuit. Should this occur, howling and inter-tube noises will be generated and the circuit will not give the good results that are desired of it. It should also be borne in mind that if more than one stage of amplification is used the transformers should not be placed too close together, and they should be so placed that their magnetic fields will not interfere with one another. It is always a good plan to place the transformers at right angles to one another. Occasionally it is of value to surround the transformers with a metallic shield, and then ground the shield. This effectively prevents interstage coupling, or noises due to the magnetic field of one tube setting up induced currents in its neighbor.

When using more than one stage of audio-frequency amplification it is generally the best practice to use a lower ratio transformer in the second step than in the first. This of course varies with the tube used, and as each type of tube has its own internal characteristics, the manufacturer generally specifies a certain ratio transformer, when used as a first or second stage.

When more than two stages of amplification are desired it is best to use what is known as the push-pull transformers, with two tubes in parallel. If more than two stages of straight amplification are used the signals will be distorted, whereas if the power amplification idea is used the signals will not be distorted due to the fact that the current is evenly divided beween two tubes and they are not overloaded.

Blind Boys Build Radio Sets



(C. Kadel & Herbert)

Making radio sets that will function efficiently is a hard task for one possessed of all his senses. But when one is blind, it is an extra hard task. Olaf Larson, Stanley Wartenberg, Christopher Cerone and George Keene, four boys from the New York Institution for the Blind, are here shown constructing a tube set under the instruction of Arthur Richmond.

A Warning About Radio Stocks

IT is natural that a field so prolific and progressive as that of radio, should attract the stock vultures who already have started out to corral the dollars of the unwary investor.

There are several good radio stocks that are worth buying.

Many of those offered are not worth even as much as a German mark.

Altheugh the Hennessy Radio Publications Corporation has a limited amount of stock of its own to sell, this is not written for the purpose of inducing any of our readers to buy a single share of it. It is written, however, in an effort to save the hard-earned dollar of our readers in cases where an investment would in all probability lead to total loss.

If you intend buying radio stocks of any kind, tell us just what is in your mind. We will make an investigation at our own expense and let you know the results. You will find that we will praise the right kind of stock investment just as honestly as we will tell you the truth about some of the wildcat radio stocks now being offered.

Address Financial Manager, RADIO WORLD, 1493 Broadway, New York City.

The Old Reliable Variometer Hook-Up

By C. C. Hermann, M.E.

I HAVE heard a good deal of complaint against the variometer hook-up, in fact so much that I decided to build a set and find out for myself whether or not such complaints are justifiable. I have had this hook-up in operation about a year and with a summer's and winter's experience in the background I believe I can safely recommend it to those desiring a variometer receiving set. Before presenting the hook-up and a description let us analyze some of the more common complaints.

Complaint number one: Difficulty of tuning due to body capacity. This trouble is experienced with variometers and can be overcome by any one of three methods of construction as follows:

1. By shielding the set. Shielding consists of a thin copper sheet attached to the back of the panel. Sheet copper of 30 gage will be just the thing. Approximately the same results can be obtained by the use of tin foil glued to the back of the panel. The shielding material must be cut away around all instruments and binding

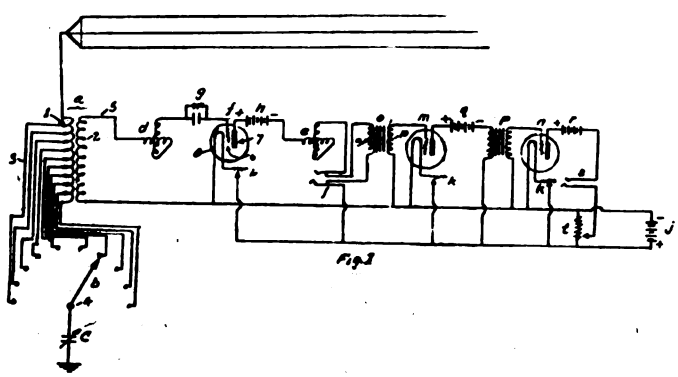

Fig. 1. Schematic hook-up of three unit regenerative set with two steps of audio-frequency amplification.

posts in order to maintain insulation between all parts of the set. The shielding material is, however, grounded to the ground binding post. Shields may also be placed between the instruments and are an assistance in tuning-in.

2. By locating the variometers a distance back from the panel. The variometers may set several inches back from the panel and a shaft extension of non-conducting material such as bakelite or hard rubber used to attach the dial.

3. By proper manipulation of the tube rheostats. If the tube filament current is turned down while tuning and when a signal is obtained then turned up to increase the volume, body capacity will be minimized.

Complaint number two: Inability to tune closely. This is due to improperly constructed instruments. The variometer, to tune closely, must be constructed with a minimum amount of clearance between the windings. It is almost impossible to obtain efficient operation with a home built variometer unless the builder is equipped with the necessary tools and has the ability to form the windings. The outer winding should be placed on the inside of the outer shell and as close as it is possible to get it without actually touching the inner winding, which is wound on the rotor.

Complaint number three: The variometer set takes up so much room. It is true that the variometer set requires more room than other types of hook-up. The variometers must not be placed too close together; however, by placing a shield between them space may be conserved. I placed the detector tube between the grid and plate variometers in my set and had good success.

Complaint number four: The variometer set costs more to build than other sets. This is primarily due to two reasons—the extra space required, as the panel must be somewhat larger for the detector and consequently a larger cabinet is required, and the variometer if of first class design and accurately constructed constitutes a higher price article.

Referring to the diagram the various elements are as follows: The variocoupler is shown at a, having 60 turns of No. 24 gauge, cotton-covered magnet wire on the stator (1) and with ten taps (3) connected to the variable switch, shown at b. The center terminal (4) of the switch is connected to a 43-plate variable condenser (*c*) of .0005 microfarads capacity. The rotor 2 of the variocoupler a has 40 turns of No. 24 gauge, cotton-covered magnet wire. A wire 5 connects one terminal of the variocoupler rotor a to one terminal of the variometer d. The variometer d and e are constructed with 56 turns of No. 24 gauge, cotton-covered wire on rotor and stator. The electrical connection between rotor and stator must be positive so that the winding is continuous, there being two terminals on the complete instrument. The variometer d is known as the grid variometer and the variometer e the plate variometer. The detector tube, which is a Radiotron U. V. 200, is shown at f. A grid leak and grid condenser of mica construction and having a fixed capacity of .00025 mfd. is shown at g, connected between one terminal of the variometer d and the grid 6 of the detector tube. The plate "B" battery shown at h is a 22½-volt Eveready T22-15 cell, with its positive terminal connected to the plate (7) of the tube f, and its negative terminal connected to one terminal of the variometer e. An "A" battery is shown at j, and used to heat the filament (8) of the detector tube f, and also the filaments of the amplifier tubes. The negative side of the "A" battery, shown at j, is connected to the remaining terminal of the variocoupler rotor 2, shown at a. Another lead is taken from the positive side of the "A" battery for the remaining terminals of the tube filaments. The filament 8 of the detector tube f is connected to the "A" battery circuit by taking a wire from one of its terminals direct to the negative side of the "A" battery. The remaining terminal is connected to one terminal of the rheostat k, the other terminal of the rheostat being connected to the positive wire of the "A" battery. A telephone jack (1) is inserted between the one remaining terminal of the plate variometer (e) and the positive side of the "A" battery. This completes the detector circuit, and by plugging in the head set nearby stations should be heard.

The tuning in is effected by turning the coupler and grid variometers (d) back and forth, first one way and then the other, and, at intervals, moving the coupler switch (b) to intermediate steps until a signal is heard. As soon as a signal is heard leave the coupler and tune as closely as you can with the grid variometer (d), then move the plate variometer until the signals are clearest. The signals may be brought in clearer sometimes by adjusting the tube rheostat (k) slightly one way or the other.

Best results are obtained by the addition of one or more stages of amplification. In the circuit shown two stages of amplification are used. The amplifiers consist of the tubes shown at m and n, and are Radiotron U. V. 201. Amplifying transformers are shown at o and p, and plate batteries of 43-volt T22-27 cells each are shown at q and r. The primary (9) of the transformer o is connected through

(*Concluded on next page*)

(*Concluded from preceding page*)

the telephone jack (1) to the plate variometer (e) and the positive wire of the "A" battery. The secondary winding (10) of the transformer o is connected to the grid of the amplifier tube m and the negative wire of the "A" battery. The plate of the amplifying tube m is connected to the positive side of the "B" battery (q), the negative terminal of this battery being connected to the primary of the second transformer (p). The filament of the tube m is connected direct to the negative wire of the "A" battery and the rheostat to the positive wire of the "A" battery. The remaining terminal of the transformer (p) is connected to the positive side of the "A" battery. One terminal of the secondary

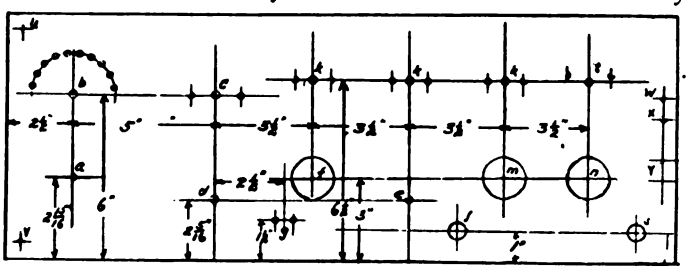

Fig. 2. Panel layout for set described herewith.

winding of the transformer (p) is connected to the negative lead of the "A" battery and the other terminal to the grid of the amplifying tube (n). The plate of the tube is connected to the positive side of the second "B" battery (r), which is identical with the "B" battery shown at q. The negative side of this battery is connected to the telephone jack (s). A wire is then connected to the remaining terminal of the telephone jack (s) and the center terminal of the potentiometer (t). The two terminals of the potentiometer are connected between the two leads of the "A" battery.

The layout of the panel is shown in Fig. 2. The panel is of bakelite, 3/16 inch thick, 8 inches high and 24 inches long. The locations of the various instruments are shown by letters, a being the variocoupler, b the coupler rheostat, c the variable condenser, d the grid variometer, e the plate variometer, f the sight hole for the detector tube, g the grid leak fixed condenser, k the tube filament rheostats, l the telephone jack for detector only, m and n the amplifying tubes' sight holes, s the telephone jack, and t the potentiometer. The lead-in binding post is located at u, the ground binding post at v, the "A" battery negative binding post at w, the "A" battery positive binding post at x, and binding posts for the loud-speaker at y.

In Fig. 3 is shown a front elevation of the panel A, a plan view of the cabinet B, and the various connections diagrammatically. The primary or antennae circuit consists of the lead-in shown at 1, connected to the binding post 2. A connection is taken from this binding post 2 to the binding post 3 of the variocoupler a. The ten taps from the primary winding of the variocoupler are shown at 4. The variocoupler switch 5 has a connection taken from its center terminal 6 to the terminal 7 of the variable condenser C. Another connection is made at terminal 8 of the variable condenser c to the ground binding post 9, from which a wire 10 goes to ground 11. The ground is preferably a water pipe; however, an iron stake driven into moist earth will give satisfactory results.

The secondary high-frequency circuit starts with the rotor of the variocoupler a. The rotor has two binding posts, 12 and 13. A wire 14 is attached to the binding post 13 and connects at its other end to the binding post 15 of the potentiometer and thence to the negative binding post w. Another outside connection is made between this binding post and the negative terminal of the "A" battery, shown at j. The second wire 16 is taken from the variocoupler terminal 13 and connects to the terminal 17 of the variometer d. The remaining variometer terminal 18 is connected to the grid terminal marked G of the detector tube f through the grid leak and fixed condenser g, mounted on the panel. The plate terminal marked P of the detector tube f is connected by the conductor 19 to the positive terminal of the 22½-volt "B" battery h. Another conductor 20 is attached to the negative terminal of this battery and attaches to the terminal 21 of the plate variometer e. The other terminal, 22, of the plate variometer e is connected, through the telephone jack l, to the primary terminal marked P of the transformer o. The other terminal of the primary coil of the transformer is connected to the negative wire 14 at the point 23 after passing through the telephone jack l. The positive wire of the "A" battery is shown at 24, and starts with the terminal marked F of the filament of the detector tube f. This conductor attaches to the terminal 25 of the potentiometer t, and has a lead 26 taken off at this point, which connects to the positive binding post x. An outside conductor connects the positive terminal of the "A" battery s, shown at j, to the positive terminal x. The other terminal of the tube filaments, shown at 27, on detector tube f, also amplifier tubes m and n, has a wire 28 connecting it with the filament rheostats k, k, k. The central terminal of the rheostat is connected by wires to the negative wire 14 of the "A" battery. It will also be noticed that one terminal of the transformer secondary coils is connected to the positive wire 24 of the "A" battery, thus completing the circuit supervised by the

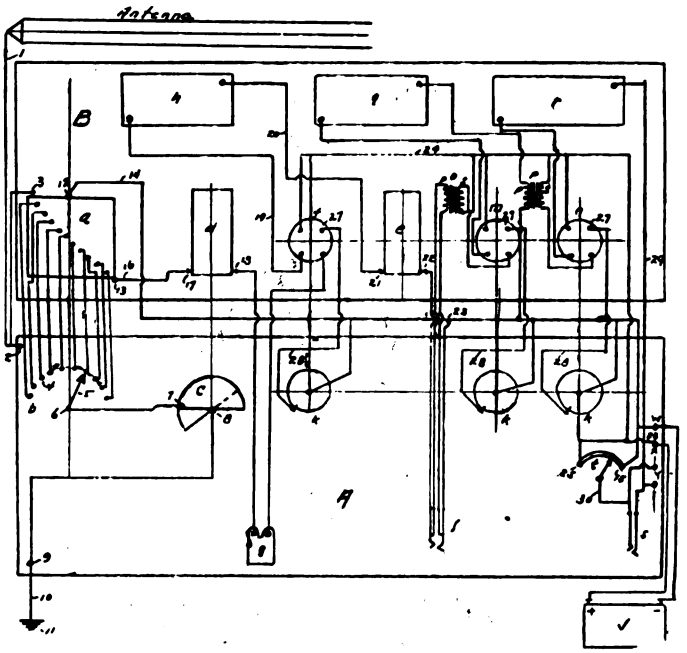

Fig. 3. Plan view of set showing location of various instruments and controls.

"A" battery. The other terminal of the secondary coil of the transformers o and p connect to the grid terminals of the amplifier tubes and marked G. The plate terminals marked P of the amplifying tubes m and n connect to the positive terminal of their respective "B" batteries, q and r; the negative terminal of the "B" battery marked q being connected to the primary terminal marked P of the transformer p, and the negative terminal of the "B" battery marked r is connected to the telephone jack s by the conductor 20. The telephone circuit is then completed by taking a connection 30 from the center terminal of the potentiometer t. Taps are also taken off of the conductors 29 and 30 to the loud-speaker binding posts y in the front of the panel.

One important matter that should not be overlooked in building a receiving set is the soldering of the connections. Every connection should be scraped clean and soldered securely to prevent corrosion and looseness. A corroded joint causes a high resistance, and the incoming signals, being weak at best, should be given the least resistance possible. All connections should be made just as short as possible.

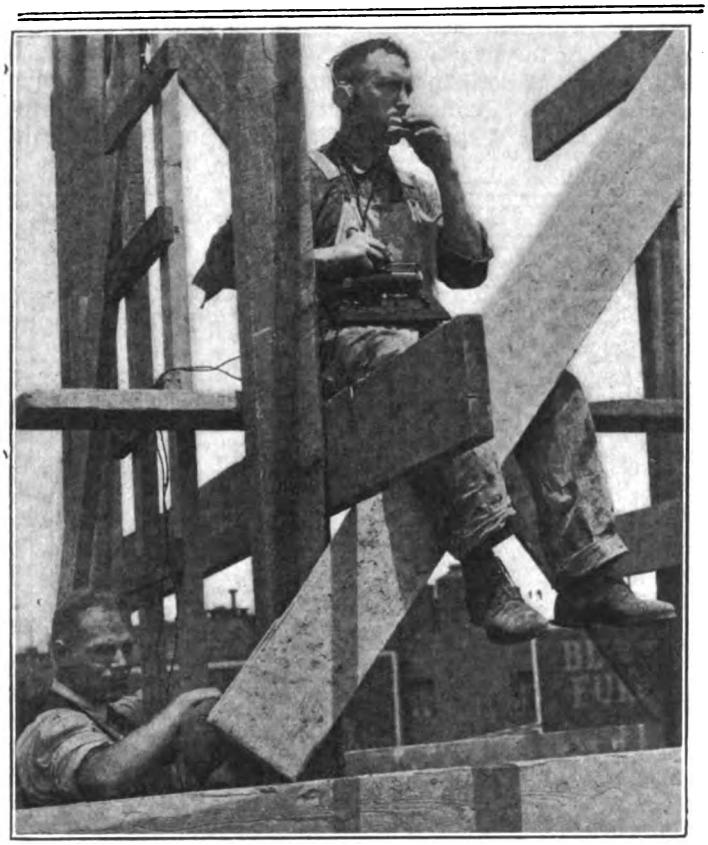
We Hope You Are Not Classified Here

THE chap who tunes by the "beat note" method and successfully establishes a record of being the best hated amateur or broadcast fan in the vicinity.

The pest who is always blowing about his DX accomplishments and then when you show up at his house tells you that he is so sorry "but my B battery just ran down."

The much loved young man who is always making a new set, with the result that his neighbors are kept awake until near morning by his hammering and sawing. And then after he gets it up, are also kept from the arms of Morpheus by his two stage loud speaker with power amplifier.



(C. Kadel and Herbert)

The bug bit him hard, as can be seen by the photograph. He takes his small crystal set along with him, and even though five stories in the air, Michael Bourke manages to enjoy WDT during his lunch hour.

The modest young man who runs over to his neighbor's house with his storage battery and asks to charge it, "because we are going to have a party tonight" and then doesn't invite you.

The bright human being that insists that you "stay just another few seconds—he must be on tonight" and keeps you for several hours while he is hunting for PWX, just when you are too tired to appreciate even Galli-Curci.

The modern scientist who insists on explaining the working of your circuit to you—whether you understand or want him to or not.

The optimist that always laughs when you blow a tube and with an intelligent expression tells you that "you can get plenty more in the stores."

The entertainer who insists on singing seventeen choruses of that popular and idiotic ditty, "Yes, we have no bananas."

Active Broadcasters Total 595

THERE were 595 active radio broadcasting stations on June 16, according to the Department of Commerce records. Of these stations, 180 are in Class A, 42 in Class B, 372 in Class C, and 1 in the experimental Class. A gain of four stations is shown over the survey made on the first of June.

During the past two weeks, 16 stations stopped transmitting and failed to renew their licenses. One new B station, located at Zion, Ill., and eight new Class A broadcasters were licensed last week, and seven Class C stations in as many states, operating on 360 meters transferred to Class A with special wave lengths. One of the new A stations licensed is in Lihue, Hawaii, which brings the total broadcasters in Hawaii to four, the three others continuing as Class C stations.

The list of stations licensed and transferred in the past week follows:

Call	New Class A Stations	Kcys.	Meters	Watts
KFHQ	Curtis Bros. Hardware Store, Los Gatos, Cal.	1,240	242	5
WABM	Doherty, F. E., Saginaw, Mich.	1,180	254	100

The Radio Woman

SINCE radio phone conversations have become so common, the old time gossip who used to take such pleasure in imparting deep, deep secrets and little bits of scandal has had quite a set-back. What formerly was common gossip and choice tid-bits are now universal knowledge to anyone with a sensitive receiver.

* * *

It used to be that a girl always respected and envied the other girl whose male friends had automobiles. Now the girl who knows a fellow who has a broadcasting or amateur phone station is the one upon whom the envy falls. And doesn't she just love to talk about "Joe's set," or "When Philly operates!"

Radio West Point Graduates Sixty-five Experts

By Carl H. Butman

GENERAL George O. Squier, Chief Signal Officer of the Army, presided at the graduation exercises at Camp Alfred Vail, New Jersey, a few days ago, when sixty-five officers received certificates as signal officers. They all completed a ten months' course in communication work, including radio in its many phases, and now have been ordered back to their regular duties with cavalry, artillery, infantry, and other arms of the service where they will act as communication specialists.

In addition to 60 regular U. S. Army Officers, there were among the graduates of the Signal School two members of the Marine Corps, one Philippine Scout, and two Cuban officers. The school, which is under the supervision of Lt. Col. J. E. Hemphill, and a corps of twelve instructors, is regarded by experts as one of the finest in the country. Many commercial schools of the type are now following the system of instruction laid down by the experts of the Signal Corps. At Camp Vail the students have the benefit of a fine laboratory and every type of radio, telegraph and telephone equipment from the lowly spark and crystal sets to the latest type of high powered tube transmitters and receivers. From the surplus material left over from the war-time equipment and new apparatus, practically every radio device known to the world is at hand for experimental and test work.

Besides the regular courses under officers of the Signal Corps, the students are given the benefit of lectures by radio and communication engineers from the big corporations and manufacturers. They also are taken on trips of inspection to large telegraph and radio terminals where they gain a knowledge of the commercial end of the work.

A little over a month ago a special class of national guard and reserve officers graduated after a six weeks' course in military communications. This special course of 350 hours of instruction, included 96 hours of radio, 31 hours of radio procedure, and 26 hours of code practice. The aim of the special course is to fit reserve and militia officers in the elements of wire and wireless communication, and school them all in the actual transmission and reception of code messages.

(C. Fotograms)
Misses Mildred and Dorothy Knapp, of Minneapolis, Minn., have taken advantage of the daily calisthenic drill on the radio program of one of the local broadcasting stations, and get up bright and early to enjoy their "daily dozen" before breakfast.

Naval Radio Monitor Control

THE question of what "monitor control" is seems to be worrying a number of radio fans who try to keep abreast of the rapidly advancing art of radio communication.

Most of them know what remote control is, the expression itself practically indicating the method of operating a distant transmitter by land lines.

Monitor control is a similar method of receiving at a station removed from local electrical interference, and transmitting the signals by land lines to the central office. A radio engineer or expert radio-man stands watch in the distant receiving station and sees to it that the receiving sets are tuned in and functioning properly during the reception of a message.

The Navy monitor control system, now used at San Francisco, San Diego and at the Radio Central in Washington, is a refinement of duplex operation. Three units, instead of one are operated; the transmitting station, the monitor receiving station, and the control or central operating office. This system is employed in the interest of efficient administration, rapidity of service and elimination of errors due to land wire relays, all activities being controlled at administrative headquarters or central office. Headquarters are frequently located where there would be interference from electric power lines or unfavorable atmospheric conditions for radio reception.

To overcome these difficulties, a monitor collecting or receiving station is established at a place free from all electrical disturbance. Signals are there received on overhead antenna or loops, and are impinged through suitable coils, on land wire loops, called "tone channels" composed of two land wire circuits between the monitor and the administration station, where the signals are transferred through suitable coils to the operator's head phones. By this method, operators are relieved of all functions except operating.

A large number of messages for simultaneous transmission and reception, including duplexing, can be handled, at the same time from Administration Headquarters. At San Diego, the monitor station is located at Point Loma, eight miles from District Headquarters. All incoming signals are monitored from Point Loma to headquarters. All outgoing signals are sent from headquarters, the operator at headquarters controlling the transmitting key at the high-power transmitting station at Chollas Heights, 12 miles from San Diego by land wire.

The monitor station is located on the roof of the Navy Department in Washington, as little electrical interference in that part of the city is found.

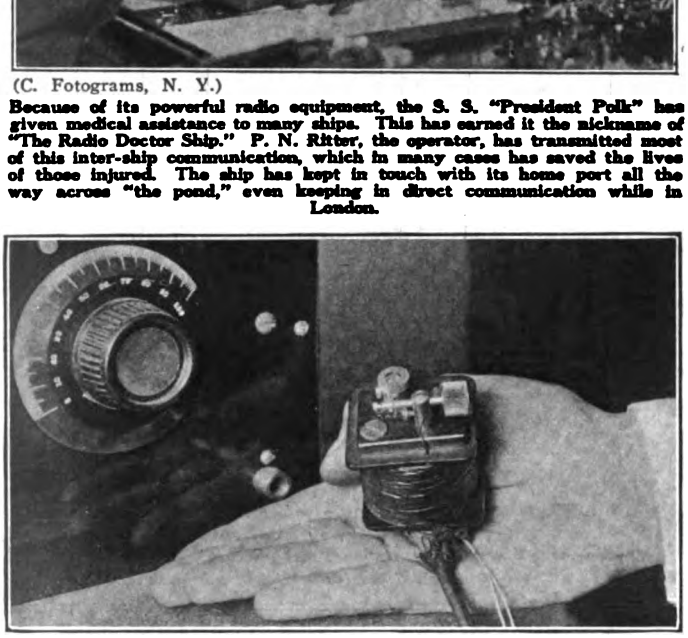
Here's Another News Pic
And A Few Words on How

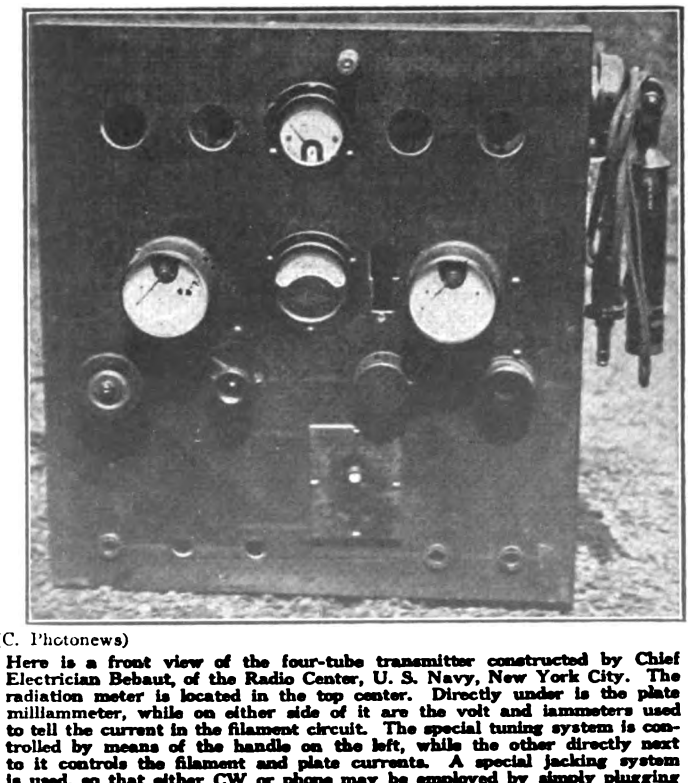
(C. Fotograms, N. Y.)

Because of its powerful radio equipment, the S. S. "President Polk" has given medical assistance to many ships. This has earned it the nickname of "The Radio Doctor Ship." P. N. Ritter, the operator, has transmitted most of this inter-ship communication, which in many cases has saved the lives of those injured. The ship has kept in touch with its home port all the way across "the pond," even keeping in direct communication while in London.



(C. Kadel and Herbert)

Although small in size when compared with its brother, the dial of which is seen in the upper left-hand corner, this minute crystal set is capable of receiving 25 miles. It consists of a tiny fixed inductance, a condenser and crystal detector, with a common pin for a catwhisker.



(C. Photonews)

Here is a front view of the four-tube transmitter constructed by Chief Electrician Bebaut, of the Radio Center, U. S. Navy, New York City. The radiation meter is located in the top center. Directly under is the plate milliammeter, while on either side of it are the volt and ammeters used to tell the current in the filament circuit. The special tuning system is controlled by means of the handle on the left, while the other directly next to it controls the filament and plate currents. A special jacking system is used, so that either CW or phone may be employed by simply plugging in the correct instrument.

(C. Kadel and Herbert)

A demonstration was recently held at the Bronx Zoological Park, New York City, to determine the effect of radio music on wild animals. It is quite evident that the lion doesn't appreciate it in the least, which same is also shown in the "hit and run" position of Keeper John Toomey.

(C. Photonews)

Olle D. Engstrom, 163 East 69th Street, a student at the Polytechnic Institute, Brooklyn, N. Y., and his radio car, which he has perfected. It can easily be operated by a distant transmitter, obeying the operator's signals instantly and without a murmer of dissent.

(C. Kadel and Herbert)

Leonard F. Plummer, who delivers letters by day and copies letters by night by means of the radio set he constructed. It is an example of very neat workmanship and careful planning. Due to the fact that most of the parts were second-hand, being bought from his friends, he constructed the set (not counting the tubes or phones) for a cost of exactly $20.00.

How Radio World G
It's Photographs

TO many people is a constant of wonder how the photographs lished in RADIO WORLD are secu order to keep them supplied with the la news.

Besides its own photographers, WORLD has on its staff one of the best photographers in the field. It is the bu of these men to ferret out all the lates penings and immediately make concre dence of them by the aid of the "ever- eye" of the camera.

Easy as this sounds it is quite a thing, because it may happen that the p rapher only overhears someone men happening or incident and then is le momentary loss as to where it happe who did it, or why it happened. To th inspired camera man this may mean around a city, seeking, probing and qu ing until he finally clicks his camera, s in the knowledge that his picture st finally and faithfully has been secured.

Of course, if there is a parade or a nary every-day occurrence it is quite e him to get his picture. But consider that the incident may necessitate his c up a big building under construction, tall radio mast, or on a precipitou in order that he may faithfully reproc incident for the public edification.

In order faithfully to serve both and us, the camera man must be up toes every minute of the day and ni cause it is no indication that just be is 5.30 that the world has gone to sl is ever prepared, day or night, to "sh subjects (in a kindly way, not otherw must have a wonderful store of inge order to gain entrance to places that tically "taboo." He doesn't know words as "It can't be done." Royalty mean nothing to him as long as he click his shutter and take away his Fear has no meaning in his vocabula simply another word—and he must in anything simply because it necessi comfort or a chance for a good fa ever alert and ever watchful.

These are just a few of the reas RADIO WORLD can give you "the nev tures" weeks ahead of any of the ra azines. With a staff of competent wakeful men constantly "on the job" ers are able to visualize the radio nev as soon as it happens.

And then, after the photogra been received by RADIO WORLD, they dergo a careful editorial scrutiny be are passed along to the engravers w the half-tone plates from which printed.

New York Amateur Builds a Neat, Compact, Portable Receiver

By Captain Adrienne Le Page

AS the trend of all construction in radio sets these days seems to follow in the tracks of "making it as small as possible," it is not at all surprising that some very fine portable sets have been made. One of the neatest and most workmanlike of these has been constructed by Bob Kalmus, a New York amateur. The set is illustrated on the front cover of this issue.

A particular point of interest in the set is the fact that the new U. V. 199 tubes are used. They lend themselves very well to sets of this type, as they are extremely small and also because they can easily be used with portable sets, as they use dry cells.

The tuning of this set is accomplished by two special variometers which are of the honeycomb coil wound type, and as can be seen take up very little space in the set. They are so placed that they are inductively related to each other. This mounting does away with the necessity of varying the coupling, as the best point was found through experimentation and then the set was constructed.

There are two stages of audio-frequency amplification used, and the transformers are mounted in such a manner that they will not cause howling. This is accomplished by mounting them at right angles to each other, and separating them quite a distance.

The extreme neatness of construction of this set should prove to prospective builders of sets that it pays to be neat. Before this set was made, the builder spent many hours planning the panel and the location of the instruments, so that they would take up as little space as possible, yet not make the wiring too intricate, or have the instruments interfere with one another electrically.

RADIOGRAMS

WORLD NEWS HAPPENINGS BRIEFLY PHRASED FOR OUR BUSY READERS

Naval Radio Station NSS, Annapolis, Md., transmits time signals daily between 3:55 and 4:00 a. m., Eastern Standard Time, on 17,145 meters.

* * *

General John J. Carty, chief engineer and vice-president of the American Telephone & Telegraph Company, received the honorary degree of Doctor of Science from Princeton University at the recent annual commencement.

* * *

Lieutenant Wilbur J. Ruble, U. S. N., who has been Fleet Radio Officer, Scouting Fleet, stationed on the U. S. S. "Wyoming," has been designated as Fleet Radio Officer of the Battle Fleet under Admiral Robison, and will be transferred to the U. S. S. "California."

* * *

A program of French music will be broadcast from WGY Schenectady, N. Y., on the night of July 5 under the direction of Professor Joseph Brodeur, organist and choir director of the Cathedral of the Immaculate Conception of Albany, N. Y. Professor Brodeur will deliver an address on "French Canadians and Their Music."

* * *

An X-ray treatment lasting 56 hours was applied to a woman cancer patient at Bellevue Hospital, New York City, last week. A voltage of 250,000 was used, and the X-rays generated were powerful enough to outline the bones of the hand at a distance of 200 feet. The patient was protected by silk and lead screens, took food and water, and occasionally slept during the treatment, which is said to be the longest on record.

* * *

Capt. Roald Amundsen, the Arctic explorer, definitely has abandoned his long-heralded flight over the North Pole in an airplane. According to a message sent to his brother, Amundsen made a trial flight on May 11 somewhere near Point Barrow. It was so unsatisfactory that the proposed flight over the pole was called off. Much had been expected of the trip by aeronauts and radio experts, as the plans called for frequent communication with Point Barrow and Spitzbergen, the final terminus of the flight.

* * *

The concerts at the stadium of the College of the City of New York, beginning this year on July 5, to run six weeks, are to be enjoyed by millions instead of the 10,000 or 15,000 of other years. They will be heard at sea, in New Orleans and Canada, past the Mississippi River and on moving trains. The music is to go out by an elaborated system of radio, and broadcast more completely than any symphony in the history of radio by the Radio Corporation of America from the Aeolian Building. Not every concert thus will be sent out, but at least two or three a week.

A. Orsi, a radio engineer of Rome, Italy, informs RADIO WORLD that Italy will now permit free radio reception, which formerly was limited to a few stations.

* * *

Station WSB, Atlanta, Ga., celebrated its first anniversary June 13. It is estimated that about 100 receiving sets in Atlanta heard the first program and that over 50,000 listened in to the birthday celebration.

* * *

Miss Vaughn De Leath, managing director, informs RADIO WORLD that the studio acoustics of Station WDT, New York City, have been properly adjusted, and that active broadcasting has been resumed.

* * *

Commander S. C. Hooper, in charge of radio engineering in the Navy, it is reported, will become Fleet Radio Officer under Admiral Coontz when the latter assumes command of the fleet early in August.

* * *

"Radio rapidly is becoming a public servant of great value, and has in it the promise of a new democracy of thought, culture and universal contact that will touch more people than ever have been reached by any agency, with the possible exception of the printing press."—Powel Crosley, Jr.

* * *

Comparison of the annual reports of the two electrical giants, General Electric and Westinghouse Electric, shows both took full advantage of resumption of business activity last year, and strengthened their respective positions in preparation for a record volume of orders expected in 1923 and subsequently.

* * *

Donald C. A. Butts, connected with the Pennsylvania State Department of Health, has announced his belief that cancer is caused by an excess of positive electric ions, or energy, in cells where cancerous growths have developed. It is only when certain cells are exposed to constant irritation, generation after generation, that a pre-disposition to cancer is inherited.

* * *

In a final tryout of the Belin telautogramme, or telegraphic transmission of written script, which is to be placed at the disposal of the public in a few days, 1,453 words were transmitted in six minutes, according to a Paris cable to the New York *Times*. The document covered 128 square centimetres, and, at prescribed rates, would cost the sender twenty francs. Under ordinary transmission by telegraph the document would require twenty-five minutes for transmission, and cost the sender 218 francs. The telautogramme was sent from Lyons to Malmaison, near Paris.

Answers to Readers of Radio World

I have constructed the Flewelling set as described in RADIO WORLD *for February 24, using mica condensers and Freshman grid leaks. The coils I wound myself. The set only responds to CFCN. I get that station very loud but nothing else. What can I do to remedy this condition?—D. P. Hartley, Jasper, Alta, Canada.*

As previously stated, this set is difficult to work. Would advise you resetting your grid leaks as spoken of in the article until the high frequency whistle is so high that it is almost inaudible. If you are not getting this scream or whistle, try switching the leads on your tickler. Also try reversing the minus B lead that goes to the filament. By that we mean instead of the lead that comes from the center of the condenser bank going to the plus of the filament circuit and then to the minus of the B battery, place it so that it goes to the minus of the filament and the minus of the B battery. As to the home made coils would advise trying some ready manufactured ones. You may have the windings wrong, or some condition may be present that would cause your set to function as it does. Watch all your connections and see that they are properly insulated and that they cross at right angles. When they are in close proximity it is best to insulate them by means of rubber tubing or varnished cambric (spaghetti). Also experiment by reversing the two coils, using the 50 as tickler and the 75 as primary and vice versa. Be careful about your soldered connections and see that the flux used in soldering has not spread. If this is the case wash the connections with alcohol to remove the excess flux. Be careful when using alcohol on or around rubber panels. If you are using a loop, try connecting the ground side of the circuit which connects to the loop through a condenser to the ground. This sometimes helps on loop reception. In any event be very careful of your construction on the condenser bank. If there should be anything wrong in this bank your set would function, but not in the correct manner, and your reception would be seriously hindered.

* * *

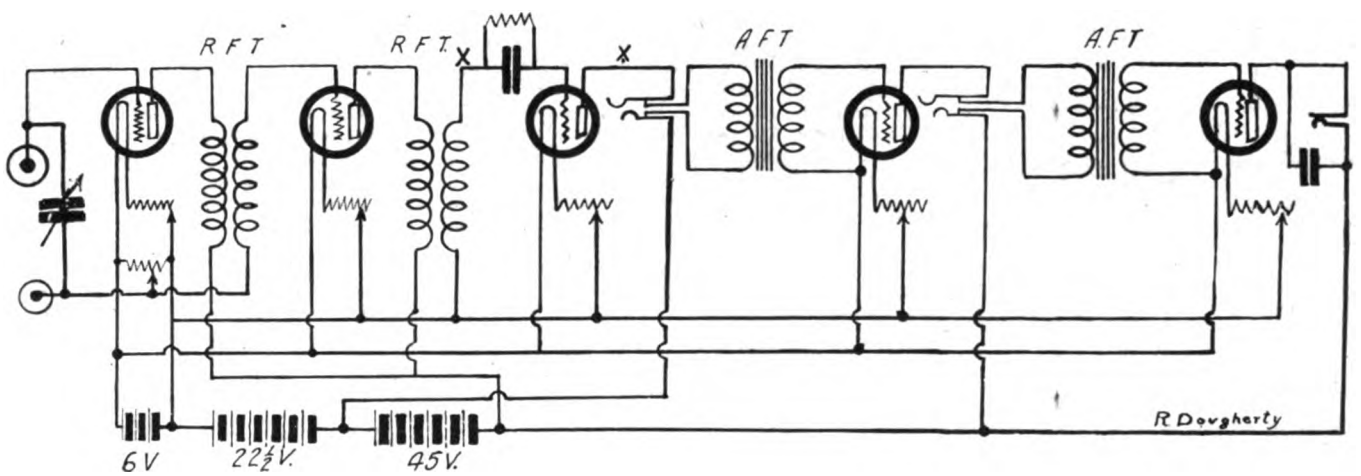
I constructed the enclosed receiver (three-unit honeycomb set) from a hook-up in RADIO WORLD. *I added the two-stage amplifier shown in the March 31 issue of* RADIO WORLD *and I cannot get it to work. All it does is squeal and howl. How can I remedy it?—Roy Smith, Lock Box 13, Millersburg, Ohio.*

The amplifier hook-up you mention was specified for the Flewelling circuit. In order to use it for the circuit you mention it will be necessary to remove the grid leak across the input of the first transformer. This is a standard two-stage audio-frequency amplifier, and will work, when the grid leak is removed, with the three-circuit receiver.

* * *

I desire to build a set that is capable of getting distant stations, and have been advised to build one incorporating two stages of radio-frequency, detector and two stages of audio-frequency. Will you please give me a hook-up for same? Can such a set be used with a loop, or are antenna and ground with a coupler necessary?—A. L. Hallam, 12 Ludlow Street, Yonkers, N. Y.

The hook-up you desire is herewith printed. It is possible to use either loop or antenna, ground and coupler with such a set. You can use either by simply connecting them across the leads shown at the extreme right. When a loop is used it will be necessary for you to shunt a variable condenser across the terminals of the loop to get tuning.



Hook-up given in answer to request of A. L. Hallam. It is two stages of radio-frequency, detector and two stages of audio-frequency. If regeneration is desired it can be obtained by simply inserting variometers in the grid and plate leads at the places marked X X in the diagram. Note that there is a 200 ohm potentiometer in the filament leads of the first tube.

* * *

In RADIO WORLD *for June 2 you published a reflex circuit by W. S. Thompson. What make of R. F. and A. F. transformers are used in this circuit? In the May 19 issue you published an improved Grimes circuit by W. S. Thompson. What make of R. F. and A. F. transformers are used in this circuit? What do you find is the average reception of this set using a loop antenna? Using an average ground and antenna? What are the proper connections for the transformers? Is it necessary to shield the panel when constructing this latter circuit? —Alfred Wagstaff, 500 Fifth Avenue, New York City; Earl W. Hoover, 309 Slocum Avenue, Syracuse, N. Y.; A Constant* RADIO WORLD *Reader, Booneville, Ind.*

It is impossible for us to specify competitive apparatus. In regard to transformers, buy the best you can get. This also applies to all other apparatus necessary to build a set. It is impossible accurately to state even the average range of any type of receiver as there are too many conditions that have to be considered. Send a self-addressed and stamped envelope to the writer of the article, care of RADIO WORLD. The letter will be forwarded to him, and your question will be answered direct. In any of the very selective and sensitive circuits it is best to shield the panel. This will lessen any chance of capacity effects.

* * *

I want to build a set that will enable me to reach from coast to coast. Will a vario-coupler variometer set enable me to do this? —L. A. Boyd, Route 1, Box 335, Hammond, Ind.

You might be able to do as you wish to by using this type of receiver, but would advise using a circuit that embodies radio-frequency amplification. If you desire to construct such a set see hook-up on this page. If you do not desire to incorporate more than three tubes the two stages of audio-frequency amplification can be left off.

* * *

In connection with the Reinartz circuit, how many turns should be put on the coils to enable me to reach all the broadcasters? What is a choke coil core constructed of? —Phil Soucy, 895 Aurora Avenue, St. Paul, Minn.

We refer you to RADIO WORLD for January 13, where you will find the information you desire, on page 23, in answer to a question similar to your own. The circuit also appears on that page, with all constants marked. The core of a choke coil is generally constructed of soft Swedish steel. Sometimes they use what are called air core chokes, and these are designated as common coils. The metallic cored choke has a lot of parallel lines shown drawn through the center.

* * *

I have constructed the set described in RADIO WORLD *for January 13, column two, circuit No. 3. I have made it without putting the condenser in the plate circuit, and it will not work. Is this condenser absolutely necessary? What is the capacity of it? Will it work when the condenser is put in?— Gorham G. Winchester, 213 Waldo Street, Providence, R. I.*

It is absolutely necessary that every circuit be constructed just as the description and diagram state. See article on page two of RADIO WORLD for June 23. It explains why. The capacity of the condenser should be .0005.

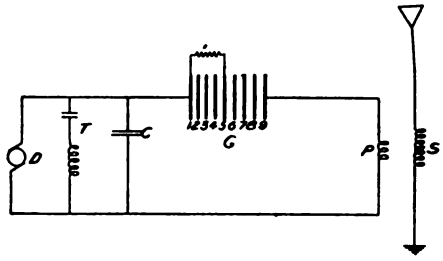
Latest Radio Patents

Radiotransmitter

No. 1,452,864: Patented April 17, 1923. Patentee: Vannevar Bush, Chelsea, Mass.

The present invention relates to radio transmitters having a primary or closed circuit of the impact type in which a series of unidirectional pulses are produced

The best known types of commercial transmitting apparatus embody an oscillating primary circuit having a spark gap and a secondary or antenna circuit tuned in resonance with the primary circuit and giving off group trains of waves. The efficient operation of this type of transmitter is dependent directly upon an accurate tuning of the two circuits, as otherwise the transference of a substantial amount of energy to the antenna circuit is precluded and the radiated energy from this latter circuit decreases rapidly. This accurate



Method of producing equal damping in spark signals.

tuning of the two circuits is difficult to obtain under ordinary conditions, and this difficulty is more particularly evident in connection with ship, aeroplane, or portable installations where the antenna capacity changes rapidly.

The resurgence of current in a persistently oscillating primary circuit, moreover, tends to heat the gap and dissipate the useful energy in the circuit, and attempts have been made to overcome these objectionable features by the provision of a form of gap which quenches or damps the oscillation, and also by providing means for artificially dissipating the heat which is generated in the gap. However, the interposition of this quenched type of gap in the primary circuit renders even more acute the difficulties due to a de-tuning of the two circuits which causes an irregular quenching action and a variation from the desired smooth tune.

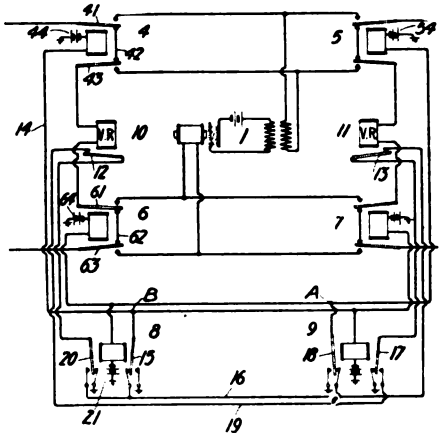
The ideal condition for a primary circuit is that in which a single loop of unidirectional current passes through the gap at each discharge of the condenser, thus ensuring the utilization of the maximum amount of energy and permitting the efficient coupling of two circuits which are not in resonance.

Repeated attempts have been made to secure a rectifying spark gap of this character which would cause the flow of a unidirectional current in the primary circuit, but these constructions have universally failed to attain the desired result, either because of the complicated and intricate nature of the constructions employed and the extremely delicate adjustments required to cause the apparatus to function in the desired manner, or because of a misunderstanding of the principles involved.

Repeater System

No. 1,455,957: Patented May 22, 1923. Patentee: E. D. Johnson, East Orange, N. J.

THIS invention relates to repeater circuits in which a one-way repeater is reversibly connected in a transmission circuit to provide for the two-way transmission of signals. An object of the invention is to provide means for connecting the repeater in circuit automatically and in response to current such as voice current impressed on the line. This is accomplished, giving rise to a very positive con-



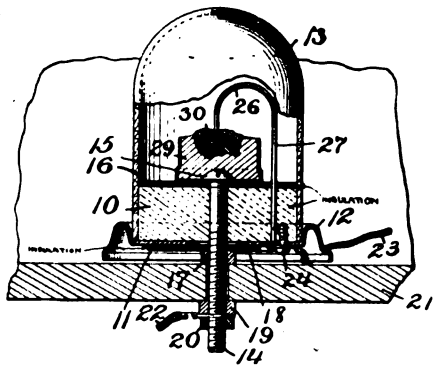
Method used for duplex or two-way transmission.

trol of the circuit connections, by providing a voice-operated relay for each of the two line terminals or sections, the operation of either relay in response to current impressed on its corresponding line section serving not only to connect the repeater properly in circuit but also to change the connections of the other control relay so that these relays will assist each other in maintaining the repeater properly connected. The assistance of the second or subsequently operated relay is of material advantage, for this second relay in the embodiment chosen to illustrate the invention and its various aspects, is connected in the output circuit of the repeater and accordingly energized.

Crystal Detector

No. 1,454,997: Patented May 15, 1923. Patentees: G. Greco and K. G. Wolff, Newark, N. J.

THIS invention relates to an improved crystal detector for wireless receiving sets, and is adapted to be placed in position in a set and is easily accessible for



Improved dustproof crystal detector.

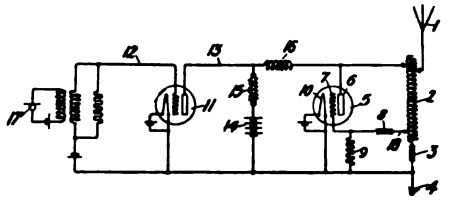
adjustment, if the small wire engaging the piece of crystal becomes dislodged from a detecting point, by the removal of the dust-proof cover, which cover fits over a block.

Oscillating Generator for Signaling Systems

No. 1,452,032: Patented April 17, 1923. Patentee: John F. Farrington, New York, N. Y.

This invention relates to oscillation generators, and more particularly to those of the vacuum tube type, and radio systems empolying such generators.

An object o fthe invention is to provide means for oscillation generators of the kind herein described whereby the feed-back coupling and hence the amplitude of oscillations can be adjusted without changing the frequency of the generated oscillations. In a transmitting station this is of importance, as the necessary adjustment of the oscillator can be made without changing the transmitted wave length. For purposes



Method employed to change the oscillatory circuit without changing the frequency.

of illustration, an oscillation generator of the audion or three-electrode vacuum tube type is employed.

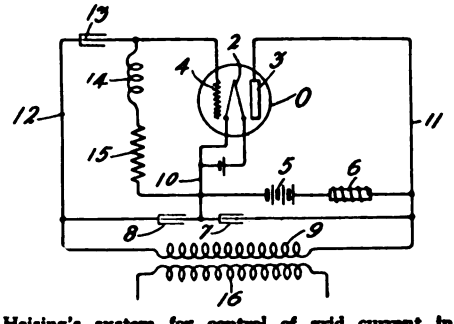
Electrical Discharge Device

No. 1,452,330: Patented April 17, 1923. Patentee: Raymond A. Heising, East Orange, N. J.

This invention relates to electric discharge devices and more particularly to arrangements for using such devices to generate, repeat or amplify electric currents.

Herefore use has been made of a high resistance leak path to discharge undesired electrical charges which accumulate upon the grid or impedance-varying element of highly evacuated electronic discharge devices. It has been found that high frequency energy is dissipated because of this resistance, thereby lowering the efficiency of such devices; and a primary object of my invention is to prevent this dissipation of energy. This result is accomplished by the means herein described without causing the leak path resistance to act less efficiently in controlling the potentials upon the grid. This saving of energy may be accomplished by allowing less high frequency current to flow in the leak path, by causing the current which does flow to be substantially wattless, or by a combination of both these effects.

It has been proposed to place the high resistance leak path between the grid and cathode, but it may be located between any two points which will cause the desired leak.



Heising's system for control of grid current in tubes.

The invention is described herein in connection with highly evacuated tubes of the audion type which function as generators, but may obviously be of utility in connection with similar or equivalent discharge devices functioning as detectors, amplifiers, modulators or for other purposes.

Some Good DX Records

From 'Way Down East

From Franklin M. Dyer, 162 Summer St., Somerville, Mass.

I HAVE been a close follower of your column, and, while I don't pretend to have established much of a DX record, I am submitting the following list of stations heard. I am using the "Greene Concert Receiver" hook-up—a very popular circuit in this section of the country.

Radiophone Broadcasting Stations—CFCA, Toronto, Ont., Canada; CHTC, Montreal, Quebec, Canada; KDKA, Pittsburgh, Pa.; KSD, St. Louis, Mo.; KYW, Chicago, Ill.; NAA, Arlington, Va.; WAAJ, Boston, Mass.; WBAP, Fort Worth, Texas; WBAH, Minneapolis, Minn.; WBZ, Springfield, Mass.; WCAE, Pittsburgh, Pa.; WDAF, Kansas City, Mo.; WDAP, Chicago, Ill.; WEAF, New York City, N. Y.; WFAU, Boston, Mass.; WFI, Philadelphia, Pa.; WGI, Medford Hillside, Mass.; WGM, Atlanta, Ga.; WGY, Schenectady, N. Y.; WHAS, Louisville, Ky.; WHAZ, Troy, N. Y.; WHB, Kansas City, Mo.; WIP, Philadelphia, Pa.; WJZ, Newark, N. J.; WLAK, Bellows Falls, Vt.; WMAK, Lockport, N. Y.; WNAC, Boston, Mass.; WNAV, Knoxville, Tenn.; WOC, Davenport, Ia.; WOO, Philadelphia, Pa.; WOR, Newark, N. J.; WSB, Atlanta, Ga.; WWJ, Detroit, Mich.; WGR, Buffalo, N. Y.; WHA, Madison, Wis.; WHAM, Rochester, N. Y.; WJAX, Cleveland, O.; WLW, Cincinnati, O.; WOAW, Omaha, Neb.; WJY, New York City, N. Y.; WJZ, New York City, N. Y.; AV8, Aviation Squadron, South Armory, Boston, Mass.

Naval and Commercial Radiotelegraph Stations and Ships at Sea—NAD, Charlestown, Mass.; NAF, Newport, R. I.; NAH, New York, N. Y.; NBD, Bar Harbor, Me.; WSA, East Hampton, L. I., N. Y.; KYP, S.S. Oneida; KEXT, S.S. Peter H. Crowell; WRS, S.S. Suffolk; KIVX, S.S. Guardsman; KUTX, S.S. Richconcal; JAH, S.S. Italy Maru (Ja.); YES, S.S. Clan Kenneth (Br.); KRF, S.S. Ramson B. Fuller; KRC, S.S. Camdem; GBWD, S.S. S. Blas (Br.); WCC, Chatham, Mass.; WNY, New Brunswick, N. J.; WCY, Cape May, N. J.; WSC, Siasconset, Mass.; NUGN, U.S.S. Potoka; KEZR, S.S. West Celina; GDO, S.S. Bovic (Br.); TXY, S.S. Breedijk (Du.); NARF, U.S.S. Wandank; KIMQ, S.S. East Side; YRD, S.S. Amarna (Br.); KMOU, S.S. Edward Pierce; KRN, S.S. Calvin Austin; KMM, S.S. Panuco.

Amateur Radiotelegraph Stations—1AAW, 1AF, 1AFT, 1AGM, Massachusetts; 1AJP, Connecticut; 1AKB, Massachusetts; 1ALJ, Connecticut; 1ANY, 1AOH, 1AOK, 1AOR, Massachusetts; 1AQI, 1ARM, ?; 1ASA, 1ASJ, 1ASK, 1ASP, 1AST, Massachusetts; 1AUA, Connecticut; 1AUH, 1BNS, 1BOP, 1BTA, 1BVH, 1BWJ, 1BXC, 1BYG, Massachusetts; 1CDO, Maine; 1CEH, 1CIT, 1CJD, 1CKB, 1COC, 1CPI, 1CPN, Massachusetts; 1CRU, Maine; 1CSH, 1CSX, 1DM, 1EO, 1JI, Massachusetts; 1KX, Maine; 1PL, Massachusetts; 1RA, ?; 1SI, 1SW, 1VV, 1DV, 1MQ, 1ZE, Massachusetts; 2AFP, New Jersey; 2BXW, 2CBC, New York; 2CGR, 2CQ, New Jersey; 2CVJ, 2TS, New York; 3BRW, Pennsylvania; 1AWH, ?; 1AWL, 1AWP, Massachusetts; 1AWU, ?; 1AX, Massachusetts; 1AXJ, Connecticut; 1AXO, ?; 1AXX, Massachusetts; 1AYZ, Connecticut; 1AZE, ?; 1BDI, Maine; 1BDT, Massachusetts; 1BET, ?; 1BHR, 1BJS, 1BLX, Maine; 1BMN, 1BNT, 1BQI, 1BTR, 1BVW, 1JV, 1PF, 1QA, 1SF, 1SN, 1VG, 1WM, 1GS, 1XM, 1WW, Massachusetts; 2AU, 2BYA, 2CG, 2CPA, 2CUZ, 2CVS, New York; 3BEI, New Jersey; 3GC, Pennsylvania; 3TR, Washington, D. C.; 3ZO, 8CKO, 8VN, Pennsylvania; 3XM, New Jersey; 8CKN, 8UF, New York.

This completes the list of stations heard to date. I don't expect that you will want to print all of these, but as so many radio fans in the West are submitting lists of stations heard I couldn't resist the temptation to show them that we, in the East, pick up a few of them also.

I find a great deal of pleasure and help from RADIO WORLD, and I wish you every success.

A Brave and True Aeriola User Makes a Request

From E. E. Williams, Woodston, Kan.

I HAVE been looking over your DX records for some time and decided to send one from Kansas, that may interest the DX nite owls. I have a single tube set (Aeriola Sr) with an aerial 18 feet at one end and 21 at other, 150 feet long from set. The following are a few of the distant stations I have heard:

South PWX, WFAA, WBAP, KOB; North CJCG, CKCK, CFAC, WLAG, WPAK, KYW; East KDKA, WGY, WJZ, WGM, WSB, WDAJ; and West KHJ, KDYL, KFI, KFDB, and many others. I have heard all told 227 stations in United States, 12 in Canada, one in Cuba and one in Old Mexico.

Would be glad to hear from Aeriola Sr. Set users to get something new to try. Will answer all letters and cards.

From the Land o' Cotton

From William Britton, 200 East 19th Street, Jasper, Alabama

HAVING read all the D-X records in Radio World I am now sending in mine. I use a one tube, single circuit regenerative hook-up with Remler, Chelsea, Allen-Bradley, parts in the set. I have heard 80 stations with this set listening in about two hours every night. During the winter I heard an average of 12 stations in two hours listening in. On several occasions I heard fifteen stations in the same time. My aerial is 90 feet long, 30 feet high at the south end and 10 feet high at the north end. The stations I have heard are, WGY, WLAG, WWJ, KYW, WJZ, WDAP, WJAZ, KDKA, WDAR, WDAF, WHB, WDAE, WDAO, WSAT, PWX, WBAV, WOAI, WIAR, WTAW, WEAM, WOAW, KFAF, WAAQ, WHAS, WBAP, WOC, WBAX, KZN, KFFQ, KFI, KWH and also Frank Jones station in Tunicu, Cuba. This only half of the number of stations I have heard.

I want to say a word about single circuit outfits. There is five in town within a radius of one mile of my house and these sets have never bothered me when I was listening in. The above record is not bad for my kind of set, eh, what!

All on the Magnavox

From Ralph Mallon, 33 East 4th St., Columbus, O.

I HAVE a three-step and Magnavox. The following stations were heard Saturday, May 26:

KDKA, 200 miles; WHAS, 200 miles; KFI, 2,079 miles; WDAJ, 500 miles; WJZ*, 550 miles; WJY, 550 miles; WOAW, 690 miles; WGY, 550 miles; WDA*, ship; WJAD*, 1,035 miles; WIP*, 435 miles; PWX, 1,400 miles; WOR, 550 miles; KHJ (speech), 2,070 miles. Total miles, 10,450. Total stations, 14. All of these were on the Magnavox. This record is better than my other record that I sent in. Since April 30 I have received 21 states, without Cuba and ships, numbering 38 stations.

MAGNAVOX

R2 Magnavox Radio *The* Reproducer Supreme

The Utmost in Sound Amplification

Where the reproduction of broadcasted programs is desired in large volume, the Magnavox Reproducer R2 should be used.

Thanks to the Magnavox (electro-dynamic) principle of construction, this result is secured with minimum electrical energy.

Without Magnavox equipment, no Radio receiving set is complete.

Magnavox R3 Reproducer and 2 stage Power Amplifier . . . $90.00

R2 Magnavox Reproducer with 18-inch curvex horn: the utmost in amplifying power; requires only .6 of an ampere for the field $60.00

R3 Magnavox Reproducer with 14-inch curvex horn: ideal for homes, offices, etc. . . . $35.00

Model C Magnavox Power Amplifier insures getting the largest possible power input for your Magnavox Reproducer.

AC-2-C, 2-stage, $55.00
AC-3-C, 3-stage, $75.00

Magnavox Radio products can be had of good dealers everywhere. Write for copy of our new booklet.

F. V. Healy, 116 South Pearl Street, Joplin, Mo.
G. E. Shutt, City Garage, Fayetteville, Ark.

The first of these names were printed in Radio World dated April 21, and have continued in each issue since. Any copy 15c. Any 7 copies for $1.00 Radio World, 1493 Broadway, N. Y.

New Radio and Electric Firms

Scotia Electric and Manufacturing Co., Scotia, N. Y., light and power plants, $5,000; J. Steinbach, W. N. Vandeberg, A. C. Neilson. (Attorney, J. H. Gould, Schenectady.)

G. Sommers & Co., St. Paul, Minn., will add a radio department. The buyer is J. A. Dieber.

Consolidated Hydro-Electric Corp., Dover, Del., manufacture motors, $100,000. (U. S. Corporation Co.)

Audio Laboratories, New York City, radio manufacturing, $5,000; V. Himmer, Jr., C. Bosworth, M. Didshun. (Attorney, S. Sprung, 291 Broadway.)

S. S. S. Radio, New York City, make parts, $20,000; M. Schier, N. Jurgrau. (Attorney, H. S. Cantor, 280 Broadway.)

Magnus Electric Co., New York City, has increased its capital stock from $100,000 to $250,000.

Radio Stores Corp., New York City, has increased the number of shares from 1,000 common, no par value, to 500 preferred, $100 each, and 1,000 shares, no par value.

Chelsea Electric Corp., New York City, $10,000; B. V. Price, J. Ort, H. Reikes. (Attorney, M. Ornstein, 147 Fourth Avenue.)

E. L. Electric Welding Repair Co., Brooklyn, N. Y., $10,000 to $20,000.

Public Electrical Supply House, New York City, $10,000; N. J. and J. and A. Feinberg. (Attorney, B. Kronenberg, 302 Broadway.)

American Manufacturers, Go After the English Trade

AN authoritative announcement reaches RADIO WORLD to the effect that the number of radio fans is increasing at the rate of fifteen hundred a week in England.

At that rate there would be an increase of about eighty thousand radio fans in England during the coming year. Due to the fact that the ratio of increase becomes greater with each new thousand it can readily be seen that England offers a fine market for the right kind of radio goods.

The suggestion is hereby made that manufacturers and distributors of American radio goods should investigate the new conditions in the English market and guide their business activities accordingly.

A New Radio Booklet

"SIMPLICITY OF RADIO" is the title of a booklet by Powel Crosley, Jr., published by the Crosley Manufacturing Company, Cincinnati, Ohio. The booklet is well illustrated and contains considerable interesting radio information, more especially referring to Crosley apparatus.

Rova Now Operates Four Radio Stores

IN the Hotel Claridge, Forty-fourth street and Broadway, New York City, a fourth Rova radio store has been opened. This store, formerly operated by Radio Reynolds, is in the heart of the theatrical district, and will cater to uptown trade.

Public Broadcasting Station Proposed for Philadelphia

ERECTION of a central radio broadcasting station, to be owned and operated publicly as one of a chain which will extend throughout the country, is asked by representatives of the National Radio Chamber of Commerce in a proposal laid before the Philadelphia Chamber of Commerce. Dr. Wilmer Krusen, chairman of the Municipal Affairs Committee of the Philadelphia Chamber, has the proposal under consideration.

The National Chamber is quoted as saying:

"The public broadcasting station must, and will, be supported by the people whom it serves. We are presenting to Philadelphia the opportunity to lead the way in the great, new development of this epoch-making art by establishing the first public broadcasting station in the United States, owned and operated by the public."

Argentina Radio Manufacturer Bankrupt

THE largest manufacturer of radio telephone and telegraph apparatus in Argentina has applied for a receivership, according to advices reaching the Department of Commerce. The financial difficulties of this company are due, it is said, to intense competition existing in the Argentine market, which resulted in considerable price cutting.

Hartzell Opens Syracuse Office

THE Hartzell Sales Company announce the opening of a branch office in Syracuse, N. Y., to be in charge of Arthur C. Smith as branch manager. The temporary address will be 1615 West Genesee street. This office will cover all of the New York State territory with the exception of Greater New York and a radius of fifty miles therefrom.

Westinghouse Suit Against De Forest in Court

THE Westinghouse Electric & Manufacturing Company began legal action last week in New Jersey against the Radio-Craft Company, Inc., and De Forest Telephone & Telegraph Company. The Westinghouse company claims the defendants are infringing on the Armstrong patent, which it controls.

Modell's Seventh Store Is Opened

MODELL'S, the well-known radio supply house, opened its seventh New York City store last week at 140 West Thirty-second street. By the autumn of this year it is expected that Modell's will be operating twelve high-class radio stores in the metropolitan district.

Standardizing Radio Equipment

By S. Herbert Mapes

ALL radio fans will remember the condition of affairs a year ago. At that time there were all kinds of fraudulent and freakish sets and parts—poor merchandise in every way—so that legitimate and reliable radio apparatus was hardly able to gain a foothold in the market.

The first step taken to bring order out of chaos was by the Federal Telephone & Telegraph Company, which started to standardize their receiving sets and parts, and guarantee every product that left their factory, in this way establishing the confidence of the public and placing radio in its true position in the field of legitimate merchandise.

This move, made by a manufacturer who has been producing quality apparatus for the past twenty-two years, will be a great help to the uniformed layman because he knows nothing about radio, and if he knows he can purchase a radio set with a guarantee from a manufacturer who is a veteran at the game then it is up to him to settle in his own mind that he wants the best and with a guarantee.

The uninformed layman who selects and purchases instruments for his radio receiver is about as likely to make a wise choice, as Edgar Felix so truly says, "as a Hindoo attempting to fit out an Arctic expedition."

He is offered the choice of an extensive line of material, each piece of which seems to have certain technical merit, and if he does not know just what to buy he is lost in a maze of indecision.

The answer to the layman's general question, "What kind of sets should I buy?" may best be answered by a consideration of what he wants his set to do—the service he expects from it.

How loud a signal does the owner want? If he can pay the price he can receive music from a broadcasting station more than a thousand miles distant and make it audible for a block or two from his house. On the other hand, he may be told that a certain station can be heard at a certain distance with a particular set, yet that signal may be so weak that it will be drowned out by the ticking of a watch.

If the buyer is content with a pair of ear phones on his head then signal strength obtained on a crystal set or vacuum tube detector will be sufficient.

But if he wants to dance to radiophone music, or if he wants to make concerts audible to as many persons as he can accommodate in a room, apparatus will be needed which produces much greater signal energy. This must be sufficient to operate a loud-speaking horn, and, except for short distances, an amplifier is necessary.

If money enough is available amplification can be provided so that a signal can be amplified to practically any degree of strength.

The type of receiver essential to obtain signals of sufficient loudness for head telephones, and the type for operating loud-speakers for various distances from the transmitting station, is, of course, something that must be determined. Every layman is confronted with questions such as these when he starts out to select his equipment. Should he spend $20.00 or $300? Should he choose a crystal set or a tube set? Should he buy head phones or a loud-speaker? What facilities has he for putting up an antenna, and what kind of antenna should he have? These are questions which the layman must decide before he makes his purchase.

During the year just passed great improvement has resulted in radio apparatus and its usefulness. Transmitters and receivers have been greatly improved, with the result that greater public interest has been stimulated. Perhaps in no other line of endeavor has there been more activity and progress through improvement of apparatus than in radio.

The primary thing to do now is for all those interested in radio to maintain the high standard of technical requirements and ask for standard, guaranteed radio products, such as the Federal Telephone & Telegraph Company manufacture.

Who Will Give This Sick Man a Radio Set?

EDITOR, RADIO WORLD: Being dependent upon an aged father for support and physically handicapped through paralysis and tuberculosis, unable to work, or enjoy life as I see others all about me enjoying it, I am led to make this appeal to you. Would you or some of your readers be willing to donate to me a radio outfit—nothing elaborate, but a simple set that I could operate successfully here in the mountains? I assure you it would bring new joys and thrills into the life of me, to whom many of the good things that others enjoy are but a dream. I sincerely thank you for any favors you deem advisable to grant me.

Sincerely yours,

36 Broadway, CHARLEY BARRETT.
Saranac Lake, N. Y.

Manufacturers, Please Oblige!

EDITOR, RADIO WORLD: Several manufacturers have not answered my inquiries for literature in other publications, and would therefore like to have you place my name with reliable concerns who wish to do business. Am in control of at least six sets and have constant use for high-grade material, but cannot learn their merits except through some understanding of their make-up.

5023 Baltimore Ave., R. J. RUSSELL.
West Philadelphia, Pa.

Calculating Inductance of Polygonal Coils

COILS wound on forms such that each turn incloses a regular polygon are finding frequent use in radio circuits. Not only are they easy to construct, but support for the wires of the coil is necessary only at the vertices of the polygon. Thus, the amount of dielectric near the wires is small, making it easy to reduce energy losses in the dielectric to a very small amount.

In Scientific Paper No. 468, "Formulas and Tables for the Calculation of the Inductance of Coils of Polygonal Form," published by the Bureau of Standards, Washington, D. C., formulas are derived for the calculation of the inductance of such coils. The cases treated are triangular, square, hexagonal, and octagonal coils. It is found that a circular coil inclosing the same area as the polygonal coil, the length and the number of turns being the same in both cases, has nearly the same inductance as the polygonal coil.

This suggests the presentation of the results in such a way as to enable the radius of the circular coil having the same inductance as the given polygonal coil to be found. Knowing this, the inductance of the polygonal coil can be found by existing formulas and tables applicable to circular coils.

The tables given show what is the equivalent radius of the polygonal coils which are likely to be met in practice. Other cases can be treated by a simple interpolation.

Coming Events

ANNUAL HOME AND CITY BEAUTIFUL EXPOSITION, featuring radio exhibits, Atlantic City, N. J., June 16 to September 8, 1923.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS, Pacific Coast convention, Del Monte, Cal., Oct. 2-5. F. L. Hutchinson, 33 West 39th St., New York.

Test Case on Broadcasting Copyrighted Music

WHETHER the broadcasting by radio of a copyrighted musical composition constitutes an infringement of the copyright law will be threshed out in a friendly suit which M. Witmark & Sons, music publishers of New York City, will bring against the department store of L. Bamberger & Co., which operates Station WOR, Newark, N. J.

The alleged infringement occurred June 4, the song being "Mother Machree," rendered vocally. The defendants will admit they have been broadcasting copyrighted music without license, the suit being primarily for test case purposes.

J. C. Rosenthal, general manager of the American Society of Composers, Authors and Publishers, in an affidavit, sets forth he offered to license the Bamberger firm for $1,000 annually, which was refused.

Mexico City Has New Broadcasting Stations

TWO radio telephone broadcasting stations were recently opened in Mexico City, a report from Consul Thomas D. Bowman, Mexico City, states. Various efforts have been made in recent months to obtain concessions for the establishment of such stations, but it is only recently that the government granted this permission.

There appears to be great enthusiasm over local broadcasting and it is believed that the market for radio sets in Mexico is favorable to considerable development by American manufacturers.

Radio sets are now sold by electrical dealers, for the most part, although some American concerns have sent direct agents to promote sales. One dealer has estimated that approximately 150 high power sets have already been sold in Mexico City. It is reported that other broadcasting stations are to be erected in Mexico.

Latest Move in Broadcaster-Music Publisher Fight

THE National Association of Broadcasters, with offices at 1265 Broadway, New York City, under the direction of Paul B. Klugh, Executive Chairman, have followed up the announcement that no performing rights royalties will be paid to copyright owners with a country-wide appeal to song-writers and publishers to turn over their mechanical royalty money to the association.

In a circular sent to music men and writers the association declares that the broadcasting of tunes is a great publicity movement, will stimulate sales, and, in fact, makes quick hits, with the following of big returns for the publishers and writers from the sale of their songs.

The American Society of Composers, Authors and Publishers holds a contrary opinion. It asserts that broadcasting hurts music sales; that it is public performance for profit, and that royalties should be collected in the same manner as from the motion picture theatres, dance halls and cabarets.

Religious Services From WMC Highly Appreciated *By George D. Hay*

HEARING a sermon for the first time in her life, after being born deaf, Mrs. J. C. Lockert of Jackson, Tenn., writes to WMC, The Commercial Appeal's radio station at Memphis, Tenn., through her husband, expressing deep appreciation of the revelation that has come to her through the medium of radio. Hundreds of cases have been reported throughout the country of deaf persons being made to hear the oral language through radio.

Following is part of Mr. Lockert's letter: "Wish to thank you for the excellent sermon by the Very Reverend I. H. Noe, dean of St. Mary's Cathedral in Memphis, which came in today through a loud speaker with such distinctiveness that it was heard throughout an eight-room dwelling and was also heard by neighbors across the street.

"In this connection I would like to say that my wife, who was born deaf, heard this, her first sermon in the oral language, by the use of ear phones. Please extend the Reverend Noe and his splendid choir our appreciation, etc."

Since WMC began broadcasting Dean Noe's sermons and the services at St. Mary's Church a month ago, hundreds of letters have been received from all over the country, expressing appreciation of the innovation.

An Episcopalian directly across the street, who had remained indoors on Sunday mornings was brought face to face with the church services through radio and forthwith decided to arise each Sunday and attend church. All of which proves that it is not a case of distance.

T. C. Scott and his family, of Leachville, Ark., are now holding open house on Sunday mornings, inviting people from miles around to take advantage of Dean Noe's sermons through their radio set.

The faculty and Normal School students of the State Agricultural College at Jonesboro, Ark., hold a "relay" service each Sunday in the school auditorium, where over 200 persons gather for the sermon.

Mrs. Aaron Allen, of Memphis, who has been confined to her room for eight years with a serious illness, heard her first sermon since she was stricken when her radio set caught St. Mary's choir and the dean's sermon.

John Myers, a world War Veteran, who has been paralyzed for four years, was also the recipient of the spiritual message.

Mrs. H. H. Cruse of Houston, Tex., reports that her little daughter, Thelma, insisted upon wearing the receiver throughout the service, to fall peacefully asleep at its close.

Dr. J. H. Lockey of Ripley, Tenn., writes that his wife could not attend her own church on account of illness, and was given the entire service from St. Mary's over the radio. C. V. Hunter of Kennett, Mo., reports that he entertains a large number in his home every Sunday with radio and WMC's service.

WMC could go on indefinitely relating instances that are reported each day, as a result of its Sunday service, through the courtesy of Dean Noe.

"B" BATTERIES

Depleted "B" Batteries are usually the cause of your trouble in receiving. Eliminate it. Buy your "B" Batteries direct from Manufacturer. No old stock batteries, but fresh tested batteries, with a 100 per cent. efficiency, at the following low prices, which are 50% less than list price.

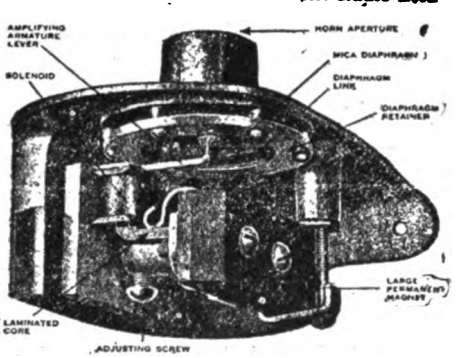
	Large	Medium	Small
22½ Volt plain	$1.25	$1.00	$0.70
22½ Volt variable	$1.38	$1.13	$0.75
45 Volt plain	$2.50	$1.75	—
45 Volt variable	$2.75	$2.00	—

Any other type of battery made to order. Send Money Order or Order for C.O.D.

ROSENDAL & CO., 2 Stone Street, New York

The Trinity Loud Speaker

The only device of its kind in the Radio field



Type "B" $12.50

TYPE "A1"
$25.00
21-in. Fiber Horn

Study the illustration carefully and you will understand why it produces full, clear, natural tones with perfect reproduction of all vocal and instrumental music. May be used with phonograph. No storage battery required.

The Trinity Loud Speaker is an instrument that combines the best qualities of a phonograph reproducer in combination with electro magnetic principles best fitted for radio amplification. Absolutely perfect reproduction of all music and speech without distortion. The volume may be regulated from that required for a room in your home to a tremendous output that can be heard hundreds of feet out of doors by simply increasing "B" battery voltage. No storage batteries required. The instrument is of a heavy duty type and is guaranteed fully by the manufacturers.

Ask your dealer for demonstration—if he cannot we can.

Two Good Reasons for Suspending Amateur Licenses

RECENTLY the license of an amateur operator was suspended by the Department of Commerce for a period of three months on account of the operator being examined within three months after a prior examination in which he failed to pass, which constituted a violation of regulation 133 of the Radio Communication Laws of the United States, which reads, in part, as follows: "No applicant who fails to qualify will be re-examined at any examining office within three months from date of the previous examination. . . . When the records of the bureau develop the fact that an applicant has failed to qualify and has applied for re-examination or been re-examined at the same or another office within three months his existing license may be suspended or revoked by the Secretary of Commerce."

In another case an amateur operator had his operator's license and station license suspended for one year for violation of Section 7 of the Act of August 13, 1912, in that he transmitted a false distress signal (SOS).

Summer Hotel Stuff

"This room is small and seems poorly furnished—one chair and a folding bed."

"That, sir, is the telephone booth."—*Louisville Courier-Journal.*

Old Friends with New Wave Lengths

The map herewith visualizes a number of stations well known to distance listeners, which are now operating on the new wave lengths. All are equipped with 500-watt Western Electric transmitters, except WHAM and WNAC which deliver 100 watts; station WMAF has both 500 watt and 100 watt transmitters. The stations shown on the map, with their new wave lengths, are as follows:

Call Signal	Station Name	Wave Length
KFI	Examiner—Earl C. Anthony, Los Angeles, Calif.	469
KGW	Oregonian Publishing Co., Portland, Ore.	492
KHJ	Times-Mirror, Los Angeles, Calif.	395
KOP	Police Department, Detroit, Mich.	360
KPO	Hale Brothers, San Francisco, Calif.	423
KSD	Post Dispatch, St. Louis, Mo.	546

THE BOY MECHANIC

700 THINGS FOR BOYS TO DO

488 Pages—700 Articles 800 Illustrations — Cloth

Price $2.00 Prepaid

The Ideal Book for the Wide-Awake Boy

All the things described in this volume have actually been built or experimented with by boys. The ideas contained in "The Boy Mechanic" would more than keep a boy occupied until he grows up and also be an incentive to original thinking and achievement.

The Most Interesting Boys' Book

Unlike so many other books of a somewhat similar nature, it is not confined to only one or a few subjects, but describes 700 different things boys can make and do in the fields of mechanics, electricity, sports, arts and crafts work, magic, etc.

An unusually generous book; size 7 by 10 in. and 1½ in. thick; printed from large, clear type on high grade book paper and durably bound in cloth. Attractive four-color cover design.

Wholesome, Practical, Instructive

Besides telling how to make scores of things useful about the house, full and complete directions are given for constructing hundreds of things which appeal to the heart of every boy.

Many hours of enjoyment are in store for the boy who becomes possessor of this book.

Price $2.00 Prepaid to Any Address

Sweden to Have Liberal Radio Laws

THE proposed Swedish law for regulating radio telephony in that country recognizes the principle of free competition with regard to the manufacture of radio apparatus. It will permit amateurs to build their own sets, requiring only that these shall be constructed in accordance with certain regulations, advices to the Department of Commerce from Assistant Trade Commissioner Sorensen state. The Telegraph Department does not contemplate limiting within narrow margins the wave lengths on which amateurs may receive.

In accordance with the proposed law the government is to erect the broadcasting stations and rent them to the Radio Telephony Company, which in turn will receive a rental from receiving stations.

No mention is made in the law regarding sending apparatus. The Telegraph Department will control receiving sets and supply them with a certain control mark, whereas the Radio Telephone Company will give permission to use such against payment of a license fee, 10 per cent of which reverts to the State for the control privilege.

Radio Waves to Fight Aircraft

German scientists were reported last week as having devised a method of putting out of commission any motor using electric ignition, by stopping its magneto with radio waves. The Los Angeles *Times* asserts that Southern California experts claim that they are able to outwit the German inventors. This is said to be possible in two ways. While the German use of radio waves of unusual potency will undoubtedly put many types of internal combustion motors out of action, other forms have been developed which can not be so affected. The *Times* goes on to say:

The success of the Siemens-Stinnes experts in Germany may stimulate especially American use of the steam turbine engine for aircraft, according to local airplane motor experts. This type, and the heavy-oil burning engine, such as the Diesel, will not be touched by the German development.

The turbine has already been developed for actual use in airplanes. Harry Peters of La Crescenta, widely known aviation motor expert of England, whose health sent him to Southern California after the war, made flights in a turbine-equipped airplane before leaving England.

A turbine engine for airplanes and automobiles has been developed at San Diego by John T. Waugh and Capt. B. H. Taylor, and, according to local airplane experts who have witnessed its operation, it works successfully, and has a much lighter weight per horse-power than the aircraft gasoline engine.

E. M. Fisk and R. S. Gradle, officers of the Commercial Aircraft Association, believe that engines burning heavy oil can be made feasible for aircraft, and that these will be made in America in the near future.

"The method reported in the *Times* cablegram has been suspected as having been developed for some time," said Bennett Harrison, of the Radio Service Company's staff. "It is feasible, for it puts the magneto out of commission and so stops any motor with electric ignition. It is surprising that the Germans conducted their experiments where the French investigators could learn of them, for their efficiency is now greatly affected.

"Experts of all nations will begin to search for means of counteracting the radio attack by developing motors which will not be subject to radio. France and England, whose main defense in future must be aircraft, are either forced to develop defensive radio control or scrap a great amount of their newly built equipment in engines.

"Radio control and interference will be enormous factors if we have another war. The influence of radio will be everywhere. Great stations like KHJ of the *Times* will have a great patriotic part, for they will reach millions on the instant and arouse and organize as was not possible in the campaigns of the past war. They will also warn an enemy of the temper of the American people.

"These stations should be considered by the Government as actually being powerful aids to defense and methods developed to protect them against any aerial interference in case of war. If possible, an enemy will cut them off from the air as surely as he would cut a cable. The possibilities of this are suggested by the report from Paris on the radio interference with aircraft motors."

Na-ald Special Socket No. 499

It's the contact that counts

A careful examination will show that each contact in Na-ald sockets and adapters is of a wiping nature on a broad surface, of sufficient tension, and so designed that tension is permanent, no matter how often the bulbs may be removed and how much the connecting prongs in the tubes vary.

Also it is little realized that sockets are being sold which, owing to faulty choice or control of material, develop current leakages from plate to grid that rob many otherwise well-made sets of their efficiency. Na-ald sockets in their design avoid all these troubles.

Construction of New Type Transatlantic Receiving Sets

By M. B. SLEEPER
Fully Illustrated. Price 75 Cents

IN addition to the listening to ships and broadcasting stations on short wave lengths there is a peculiar fascination about listening to the high-power telegraph stations of England, France, Germany, Russia and Italy as well as those located in the Pacific Ocean and the Oriental Countries. It is much easier to do this than most people imagine. The sending is very slow, a feature of assistance to the beginner in telegraphy. Several types of receiving sets for this task are described. Detectors, amplifiers, oscillators, etc., for long distance reception are also described. Suggestions for the operation of relays by the signals and the reproduction of them on a phonograph are given. In addition there is some valuable data on home made wavemeters for testing and experimenting.

IMPORTANT NOTICE

While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

United States Civil Service Examination

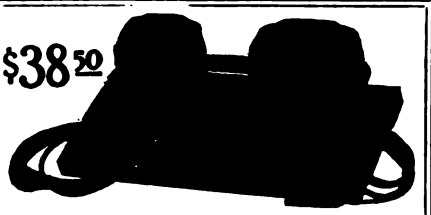
THE United States Civil Service Commission announces an open competitive examination for laboratory assistant, senior grade.

The examination will be held throughout the country on September 5 and 6. It is to fill vacancies in the Bureau of Standards, Department of Commerce, at entrance salaries ranging from $1,200 to $1,380 a year, plus the increase of $20 a month granted by Congress, and vacancies in positions requiring similar qualifications.

Examination will be given in the following optional subjects: Advanced general physics, ceramics, chemical engineering, civil and mechanical engineering, electrical engineering, paper technology, physical metallurgy, physics and chemistry, and textile technology.

Applicants must have graduated from a four years' high-school course, and, in addition, must have completed at least 90 credit hours of study in a college or university of recognized standing, majoring in the optional subject selected unless the optional chosen is physical metallurgy or physics and chemistry. Competitors will be rated on general chemistry and elementary physics, mathematics, optional subject and education, training and experience.

Full information and application blanks may be obtained from the United States Civil Service Commission, Washington, D. C., or the Secretary of the Board of U. S. Civil Service Examiners at the post



$38.50

RECHARGE YOUR OWN BATTERIES

WHY pay out good money constantly for recharging batteries when the Ohio Motor Generator will do it quickly at a slight expense. This inexpensive home charging outfit keeps your Radio in service all the time and pays for itself—by charging your neighbors' batteries. It is noiseless, gives no trouble, and will even recharge totally exhausted batteries quickly.
The set is made up of the celebrated Ohio A C motor and D C generator wound for 6-10 volts. The motor and generator have ball bearings and are of the highest grade construction. It has none of the troubles common to cheap charging sets and will last a lifetime. It will charge quickly any three cell automobile or Radio "A" battery. Furnished complete on a substantial base with ammeter and field rheostat to adjust the charging rate from one to twenty amperes. The motor is for 60 cycle, 110 volt service and is complete with ten foot cord and attachment plug ready for instant connection and operation. Full instructions provided.
Motor and generator can be specially wound to charge six cell batteries or other unusual conditions.
Price $38.50 f. o. b. Cleveland. Ship by Express C. O. D. weight sixty pounds. Send your order today and stop paying good money for recharging. Your money back quick if not satisfactory.
NOTE:—If your service is other than 60 cycle, 110 volt, ask for special price.

Joe Jackson Tries Radio

(C. Fotograms, N. Y.)

Joe Jackson, the funny man of the stage, getting quite a "kick" out of hearing other funny people being funny over the air. It is said that Joe can be just as side-splitting manipulating his radio set as he is when riding one of his trick bicycle wheels and keeping people in roars of laughter. The only difference is that we can't even pay to see Joe get funny with radio. It would give us heart failure every time we thought about a new tube.

Government Tests of Radio Receiving Sets

DURING the past two years the radio laboratory of the Bureau of Standards has been developing methods of testing radio receiving sets, and has made tests on receiving sets of a number of different types. The results of the tests on these sets are given in a series of letter circulars which are in preparation. The first letter circular in this series is designated as Letter Circular 90, and has recently been issued. The sets on which tests are therein described are regenerative sets using electron-tube detectors and are of the type intended for such use as the reception of continuous wave signals from arc transmitting stations on wave frequencies down to 60 kilocycles (wave lengths up to 5,000 meters).

The Bureau of Agricultural Economics, U. S. Department of Agriculture, on account of its interest in the reception of crop, market and weather reports by radio, has assisted in this investigation. The particular receiving sets studied are referred to by arbitrary reference numbers rather than by a statement of the manufacturers' names and type or model numbers. It is believed that the methods followed and the examples given in this circular will be of assistance to manufacturers in the development of methods of testing and describing their own products, and thus improving them. It is believed that purchasers will also be directly aided in deciding what features and characteristics to look for in the selection of apparatus.

A limited number of mimeographed copies of Letter Circular 90 are available, and can be secured by those who are directly concerned with the testing of receiving sets by addressing the Bureau of Standards, Department of Commerce, Washington, D. C.

Measuring Properties of Electrical Insulating Materials

THE Bureau of Standards at Washington, D. C., states that it receives frequent requests for information on the methods which it has found practicable for making measurements of properties of electrical insulating materials. The methods are described in Scientific Paper No. 471, "Methods of Measurement of Properties of Electrical Insulating Materials."

In Technologic Paper No. 216, "Properties of Electrical Insulating Materials of the Laminated, Phenol-Methylene Type," the authors have indicated the reasons for selecting certain of the physical properties for measurement in a research on electrical insulating materials. The same considerations apply in the measurement of many types of insulating materials besides the laminated phenolic materials. The information obtained by making measurements for a given material on all these properties is quite comprehensive. The properties for which methods of measurement are given are: Phase difference and dielectric constant at radio frequencies, voltage effects at radio frequencies, volume resistivity, surface resistivity, density, moisture absorption, tensile strength, transverse strength, hardness, impact strength, permanent distortion, machining qualities, thermal expansivity, and effects of chemicals.

¶ "Radio," the San Francisco magazine, is a very excellent publication. We have made arrangements with the publishers by which we are able to offer for a limited time only a six months' subscription for RADIO WORLD at the regular price of $3.00 and also "Radio" for six months without extra cost.

¶ Send your $3.00 at once, as this offer is open only until July 30, 1923.

CUT OUT AND MAIL TODAY

Special Radio World and "Radio" Subscription Blank

RADIO WORLD, 1493 Broadway, New York City.

Enclosed herewith find $3.00 for which please send RADIO WORLD for six months beginning with issue of ..... and "Radio" for six months, beginning with issue of ..... There is to be no other charge to me.

You may, if you wish, send remittance for $6.00 and receive RADIO WORLD for one year (52 issues) and "Radio" for one year without extra cost. This offer good only until July 30, 1923.

Another Satisfied Subscriber

EDITOR, RADIO WORLD: Find enclosed a check for $3.00 for my renewal subscription to RADIO WORLD, beginning No. 66, dated June 30, 1923, for six months. I am proud to say that I have been a subscriber to RADIO WORLD for nearly a year and have found it to be the best radio magazine to be had. It handles everything in radio to perfection.

Yours truly,
KENNETH H. JONES.
London Mills, Illinois.

Two New and Valuable Radio Helps

Two new and remarkably good radio books by M. B. Sleeper —one is entitled "Six Successful Radio Sets," with design data and instructions for receiving sets specially selected for exceptionally long distance reception. The other is "101 Receiving Circuits," being a most complete compilation of diagrams including circuits for a generative, superregenerative, Reinartz, Flivver, Flewelling, super-heterodyne, reflex and radio frequency sets. Each book mailed on receipt of fifty cents and ten cents extra for postage. Both books for $1.00 and no extra charge for postage. The Columbia Print, 1493 Broadway, New York City.

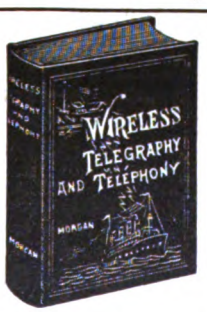
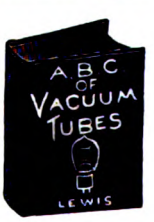
Telling How to Operate a Radio Set—How to Build a Set—Principles of Vacuum Tubes and Other Radio Problems



Wireless Telegraphy and Telephony Simply Explained

By ALFRED P. MORGAN

One of the most complete and comprehensive treatises on the subject ever published. A study of its pages will enable one to master all the details of the wireless transmission of messages. The author explains in simple language the theory and practice of wireless telegraphy and telephony. 154 pages, 156 engravings.....PRICE $1.50

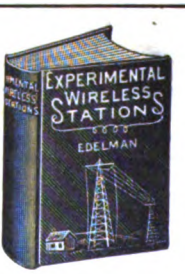


The A B C of Vacuum Tubes Used in Radio Reception

By E. H. LEWIS

Assoc. I. R. E., and Radio Instructor

Written particularly for the person who "knows nothing about radio," but who would like to gain an understanding of the elementary principles of operation of vacuum tubes and various circuits in which they are used for the reception of radio-telegraph signals and radio-telephone music and speech. Illustrated.....PRICE $1.00



Experimental Wireless Stations

By P. E. EDELMAN

Tells how to make apparatus to not only hear all telephoned and telegraphed radio messages, but also how to make simple equipment that works for transmission over reasonable long distances. Then there is a host of new information included. The first and only book to give you all the recent important radio improvements, some of which have never before been published. 392 pages, 167 illustrations.....PRICE $2.00

THE BOY MECHANIC

700 THINGS FOR BOYS TO DO

480 Pages—700 Articles 800 Illustrations — Cloth

Price $2.00 Prepaid

The Ideal Book for the Wide-Awake Boy

All the things described in this volume have actually been built or experimented with by boys. The ideas contained in "The Boy Mechanic" would more than keep a boy occupied until he grows up and also be an incentive to original thinking and achievement.

The Most Interesting Boys' Book

Unlike so many other books of a somewhat similar nature, it is not confined to only one or a few subjects, but describes 700 different things boys can make and do in the fields of mechanics, electricity, sports, arts and crafts work, magic, etc.

An unusually generous book; size 7 by 10 in. and 1½ in. thick; printed from large, clear type on high grade book paper and durably bound in cloth. Attractive four-color cover design.

Wholesome, Practical, Instructive

Besides telling how to make scores of things useful about the house, full and complete directions are given for constructing hundreds of things which appeal to the heart of every boy.

Many hours of enjoyment are in store for the boy who becomes possessor of this book.

Another Appreciative Subscriber Heard From

Editor RADIO WORLD: In your April 14th issue there appeared an interesting article by Arthur S. Gordon entitled "Build Me," giving details for a very clever set.

At the time this issue came out I was in the throes of construction, being at work upon a two variometer set. I had my variocoupler, inductance switch and condenser all in and was about ready to purchase the variometers when along came your article and changed everything. I read the article very carefully and while I could not follow the exact instrument placings I could follow the hook up. So I built the set and it's a wonder! I used a Pioneer coupler, Walnart 43 condenser back panel inductance, Acme transformer cartridge grid condenser and leaks in triple mount, wiring two grid mounts in series giving me a variance of grid from one to five by using several grid cartridges of different values.

I have a beautiful set in golden oak cabinet carefully wired and it has been admired for beauty of finish by all who have seen it. And it works beautifully sweet and clear.

Before I had an aerial up I hooked it to the bed springs. One night got Memphis WMC, another night WHB Kansas City and another night WOAY Birmingham, all on the bed springs. I have just put up an aerial and through a bank of static that has camped around here with the present heat wave I enjoyed San Antonio WOAI Sunday evening concert clear as a bell. So all in all this answers your query on page 6 of April 14 issue: "Why do you read RADIO WORLD?"

I believe the fundamental desire of the public generally is to be enlightened upon the intricacies of radio; to have their small knowledge of the art given food upon which to develop a better understanding of it. This RADIO WORLD is doing. I see every issue. It is only deserving that it should be as popular as it is.

W. RITT CHANDLER.
Box 716, Clarksdale, Miss.

Broadcasting Popularizes at Least One Song

In an article on radio and the music industry written for *The Music Trades*, E. F. McDonald, Jr., of the Chicago Radio Laboratory, quotes this interesting incident:

A typical example of the effect of broadcasting on vocal music was furnished by the testimony volunteered at the first meeting of the National Association of Broadcasters when Mr. Wendell Hall, a song writer, made the declaration that "Mellow Moon," which he had written, made no appreciable headway in the hands of a publisher who resorted to the usual avenues open to publishers for exploiting a new musical creation. There was practically no sale. Then Mr. Hall began singing "Mellow Moon" at KYW and WDAP broadcasting stations. He stated that in the month of April the sale of "Mellow Moon" jumped to 100,000.

Making the Set Was Easy!

LITTLE JOE had completed his crystal receiving set and had made it "work." His astonished and proud mother said to him:

"Wasn't it very hard to do all this?"

"Naw," said Joe; "most of it was easy as anything."

"What was the hardest part of it?" she asked.

"Gettin' eight plunks out of pa," said

Scientific Radio Laboratory
25 THIRD AVENUE NEW YORK

Construction of New Type Transatlantic Receiving Sets

By M. B. SLEEPER

Fully Illustrated. Price 75 Cents

IN addition to the listening to ships and broadcasting stations on short wave lengths there is a peculiar fascination about listening to the high-power telegraph stations of England, France, Germany, Russia and Italy as well as those located in the Pacific Ocean and the Oriental Countries. It is much easier to do this than most people imagine. The sending is very slow, a feature of assistance to the beginner in telegraphy. Several types of receiving sets for this task are described. Detectors, amplifiers, oscillators, etc., for long distance reception are also described. Suggestions for the operation of relays by the signals and the reproduction of them on a phonograph are given. In addition there is some valuable data on home made wavemeters for testing and experimenting.

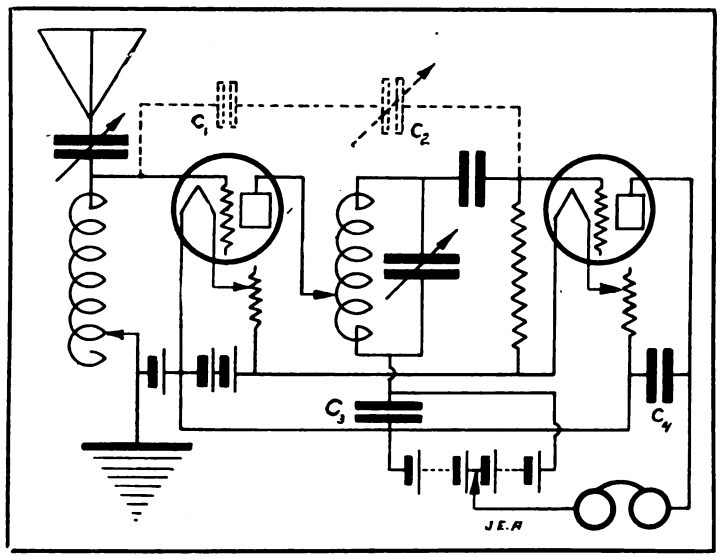
The Nite Owl Special

By J. E. Anderson, M.A.

IF you are in pursuit of the elusive DX signals that nightly fill the ether, you are also in pursuit of new circuits with which to bag your game; and here is one which undoubtedly will interest you. It will coax the signals from the farthest recesses of the ether and literally hurl them against your ear drums, and you don't have to guess what call letters were used as missiles either. But the circuit is somewhat difficult to manipulate at first and is likely to become a storm center in the neighborhood until the operator has learned to obtain maximum signal strength without generating a lot of "birdies." With a little practice it is possible to tune it in on almost any signal and bring it to the very brink of oscillation without once letting it "spill over."

The new feature of this circuit lies in the interstage coupling which was first suggested to me by Mr. W. A. Marrison, of the Western Electric Company, who has obtained remarkable DX results with a circuit similar to the one described here. Using this type of coupling between two stages of radio-frequency amplification and between the second stage and a tuned crystal detector, he picked up stations 1,500 miles away on a very small indoor antenna, and the circuit was extremely selective. The present circuit is not nearly so selective, but it is easier to manipulate and not nearly so critical. There are several means by which the regeneration may be easily controlled.



Circuit diagram of receiver utilizing super-tuned radio-frequency. The neutralizing capacities are optional, but will aid in reception if used.

A glance at the accompanying diagram will show that the circuit consists of one stage of radio-frequency amplification and a detector and that the two tubes are coupled by a tuned auto-transformer. Thus the plate circuit of the first tube is tuned and this makes the first stage regenerative. The reaction between the plate circuit and the grid of this tube may be regulated by varying the amount of inductance in the plate circuit. For this purpose the interstage inductance coil is tapped at about every five turns and the plate lead of the first tube tied to one of these taps. Maximum reaction is obtained when the plate is tied to the upper end of the coil and minimum reaction when it is connected to the lower end. As the reaction is reduced the coupling between the two tubes is also reduced, but at the same time the ratio of transformation is increased. The plate potential of the first tube is supplied through the windings of the interstage inductance coil and hence the grid condenser of the detector tube serves the double function of blocking the grid current of detector and preventing the plate potential of the first tube from reaching the grid of the second. Therefore the insulation of this condenser should be of the highest order. The grid leak resistance of the detector is connected directly from the grid to the positive side of the filament. The values of these two elements do not differ from those used in other circuits. The condenser C_3 is a by-pass across the "B" battery and serves the usual purpose of furnishing a low impedance path for the high frequency currents. Its value should not be less than .005 mfd. Condenser C_4 serves a similar purpose for the detector tube, but its value needs to be not greater than .001 mfd. The detector tube, as shown in the drawing is not regenerative but if desired it may be made so by one of the usual methods. If this is done the first tube should be operated at a point considerably below regeneration, or the circuit will be entirely unmanageable.

The two inductance coils in this circuit should be somewhat larger than is customary in order to obtain regeneration on the longer broadcasting wave lengths. From 60 to 75 turns on a 3.5 inch tube is about the minimum for the antenna coil and 60 turns on the same size tube for the interstage coil. The antenna coil should be tapped so that it may be varied in steps of from two to five turns and the interstage coil in steps of five turns.

These large coils require small condensers. Twenty-three plate condensers may be used but 11-plates are better. It will be found that signals come in loudest when small values of capacity and large values of inductance are used and the smaller condensers will give the necessary fine variation in tuning. This com-

Studying Radio Code While Asleep

By Carl H. Butman

WASHINGTON, D. C.—Studying radio code while asleep may be the boon many amateurs are awaiting to insure a higher rate of reception. In any event, this method of instruction has been tried in the Naval Air Station at Pensacola with the result that backward students have improved their speed.

Due to the fact that many of the embryo aviators, who receive their radio instruction at the Pensacola Naval Air Station, have been unable to copy at a rate of twenty words a minute, the novel method of continuing to send to them while they are asleep, with their receivers in place, has improved their speed when awake.

The method, which was devised by Chief Radio Mate Phinney, in charge of radio instruction, gives every indication of becoming practical and valuable, naval radio experts believe, although some of them want to observe personally its application.

Chief Phinney, who is a student of the old school and served in the war as a commissioned officer, claims that the plan will aid in teaching students high-speed reception while asleep, increasing their facility in receiving in a fraction of the time ordinarily required in wakeful hours. Several students who were in danger of flunking their radio have been saved that ignominy, he claims, by instruction while they slept in their "ear-muffs." Subconsciously they continued to listen-in. The inventor conceived the idea of subconscious instruction following a personal experience. While practicing receiving at a rate of thirty-five words a minute, he feel asleep, but the mechanical transmitter continued to send to him. When he awoke, he declared he was able to receive at the thirty-five word rate, although previously he could only copy at twenty and twenty-five. His theory is that during his few hours of slumber his sub-conscious mind was trained to receive at the higher speed.

Skepticism greeted his early proposals of sleep instruction, but now even the skeptics admit the plan is workable. Requirements in the radio section of the flying school provide that within six months students acquire a speed of twenty words per minute before they can become pilots. This is a bugbear to many. In the last class several students proved difficult subjects and as a last resort the new method was tried to boost their speed.

Before they turned in, these students adjusted their head receivers and soon after "taps," an expert operator began to send at a rate of about ten words in excess of their capacity to receive. All through the night the messages in code went on, the operator at the key being relieved from time to time. In their conscious hours the following day, most of the students were able to receive messages at the speed sent to them while they slept.

Here is an opportunity for amateurs to improve their speed by picking up some naval ship or station sending code at night and sleeping with their "ears to the air" as it were. Many amateurs, as well as commercial operators, have experienced the aggravating continuation of the "dit-da-da" long after they have ceased to listen in, following a long session of receiving. This is practically the reverse of the method proposed, in that it is the continued operation of the subconscious mind and ear, which have adapted themselves to a code speed, although the messages have ceased. Some amateurs plan to try the method, as they all find a maximum speed point in reception which they are unable to pass for some time.

(*Concluded from preceding page*)

bination renders the circuit less selective than it would be if large condensers and small inductances were used, and for this reason only the very best condensers should be used and special precautions should be taken to select coils that have a low distributed capacity and low effective resistance.

This circuit is liable to raise a veritable bedlam of noises while tuning it unless this is very carefully done. To tune the circuit to any wave length within its range use as small values of inductance as possible both in the antenna and the plate of the first tube, and vary both the variable condensers until both circuits are in exact resonance with the desired wave length. If it starts to oscillate reduce the inductance some more and tune again. When both circuits are in tune the strength of the signal may be increased by gradually increasing the inductance in the antenna or plate circuits and retuning. A variation in the plate inductance of the first tube will have little effect on the tuning of the interstage coil as will be seen from the connection in the drawing. Two taps will soon be found on either coil such that the circuit will oscillate on one while it will not on the tap just below. If the signal is satisfactorily loud on the tap on which it will not oscillate this should be used, otherwise the first tap on which it will oscillate should be used. The oscillations may then be stopped by detuning one of the circuits slightly.

A third method of controlling the regeneration is suggested by the dotted lines in the drawing. Since the neutrodyne principle is a means of neutralizing the cause of regeneration in a circuit of this nature, it is evident that it may also be used to control the amount of regeneration. This may be done by inserting a small neutrodyne condenser between the two grids of the circuit and varying its capacity over the necessary range. This condenser must be very small and it must be capable of very fine variation in capacity. The finest variation in capacity may be obtained by connecting a small fixed condenser in series with a large variable one. In my experimental circuit C_2 was a variable 23-plate air condenser, but an 11-plate or a 3-plate will do equally well. C_1 was made by twisting together the ends of two pieces of No. 22 double silk covered wire. One to three turns were found to be sufficient.

If greater selectivity than this circuit will give is desired a double circuit tuner may be used in the first stage. But this circuit is extremely difficult to manipulate owing to its critical nature. However, it may be controlled in a similar manner to the single circuit tuner discussed above. It may further be stabilized by keeping the antenna circuit accurately in tune with the secondary and the interstage coils and by increasing the coupling between the antenna and the secondary. But these conditions, unfortunately, will cause greatest re-radiation and interference with neighboring sets when it does oscillate.

Skyscrapers Absorb Radio Waves

By C. W. Tucker

ARE you in a dead spot? Quite a lot is being heard these days about dead spots. Baltimore cannot hear Washington radio stations. Pittsburgh radio stations are silent to Cleveland's ears. Yonkers hears New Jersey stations much better than New York City stations, although it is on the outskirts of the city.

An interesting study of this matter has been made by Bell System engineers in connection with the transmission from stations 2XY at 24 Walker Street, 2XB at 463 West Street and 2XW on the Municipal Building, New York City. As will be seen from the chart herewith there is a sharp decline in the strength of the radio fields of each of these stations in an almost direct northeasterly direction. The fields are very much weaker in an east and southeast direction, than they are on the west side. The line of the weakest field in the northeasterly direction is directly over a mass of skyscrapers in the Times Square district, while in the southeasterly direction, it leads over the skyscrapers in lower Manhattan and the eastern end of Brooklyn. For this reason, it has been assumed that the steel in these buildings absorbs the radio waves.

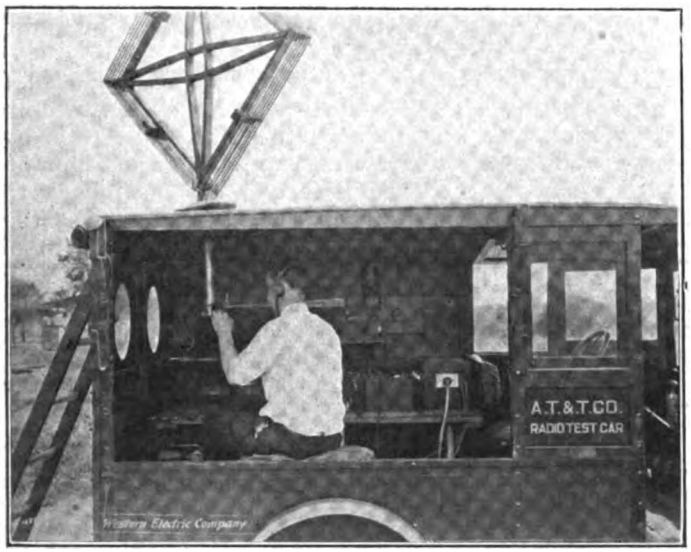

Fig. 1. Western Electric test car which recently made efforts to solve the problem of "dead spots" in radio reception around New York City.

This chart is really made up of two maps. The circle and the lines have no reference to distance but to the field strength of the broadcasting stations in microvolts per meter. The lines show the direction in which the readings were taken. The black dots represent the strength of the field in that particular direction. The lines connecting these dots do not represent the strength of field between the dots but are merely drawn in to show which station the dot represents.

Special measuring apparatus was developed in the Bell System Laboratories of the Western Electric Company for measuring the field strength of the different broadcasting stations. Essentially the process is one of measuring the current produced in a calibrated antenna by the incoming radio waves. Since these currents are very small they cannot be measured directly but a comparison method is necessary. An oscillator in the measuring set produces a small but measurable radio-frequency current, a very small part of which is picked off by a calibrated potentiometer and fed into the antenna. A receiving set also connected to the antenna is used as an indicator to tell when the currents produced in the antenna by the distant and local sources are equal.

Where the transmitting station is co-operating or under control, the distant and local signals may be introduced separately and alternately and their efforts on the receiving set compared by means of an indicating instrument attached to the output of the receiving set.

When the transmitting station is not co-operating, the use of a loop antenna permits it to be cut out when the local signal is introduced by turning the loop 90° to the directional blind spot. If desired, the antenna may be cut off entirely, and the comparison made directly against the local source feeding into the receiving set.

One of these measuring sets was made up and mounted in an automobile truck. The loop antenna is placed on top. This set was used in making a study of the field strength of the broadcasting stations mentioned above. It was found that at 400 meters these stations are handicapped in transmitting through the maze of steel structures of Manhattan. Also, it is apparent that the two high buildings are less favorable sites than the 14-story building at 2XB.

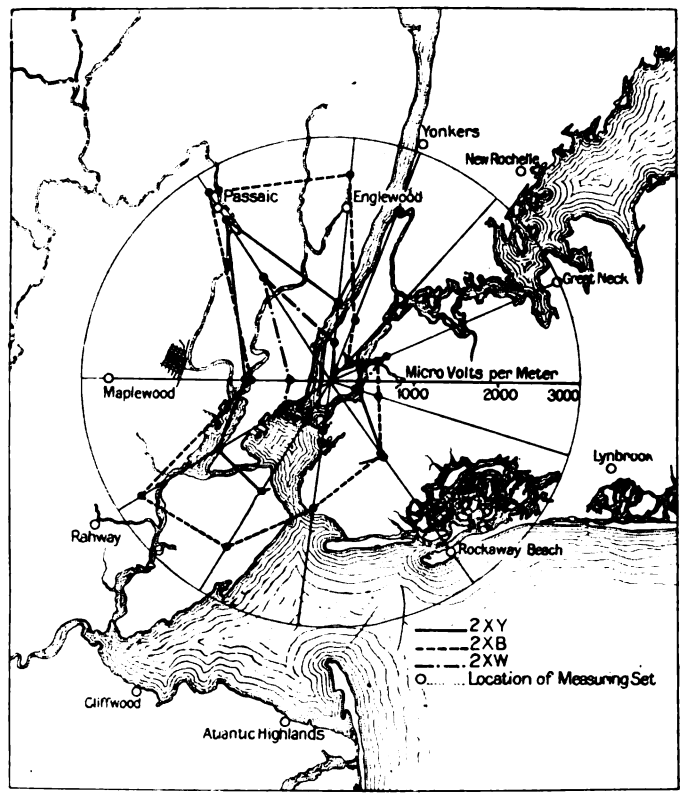

Fig. 2. Map showing the results in field strength of various stations taken at several places for the tests on "dead spots."

The results obtained demonstrated that field measuring sets are valuable experimental tools. For this reason, a set was built employing the Western Electric "N tube" or what is properly known as the "peanut tube" throughout. This outfit, together with the loop, which is collapsible, can be placed in two suitcases such as are used by traveling salesmen for carrying samples

Dr. MacMillan Begins His Arctic Voyage—Radio Reports Received

Dr. MacMillan in Arctic costume—parka and mukluks

THE 89-foot schooner "Bowdoin," bearing Dr. Donald B. MacMillan and his party on their way to resume scientific work and explorations in the Arctic, sailed from Wiscasset, Maine, on June 23. The work begun on the Baffin Land expedition, from which Dr. MacMillan returned in September with the greatest collection of scientific and magnetic observations ever made in the Arctic, will be continued in Ellesmere Land, Northern Greenland. While he expects to return in fifteen months, Dr. MacMillan may be compelled to stay until the fall of 1925.

The party includes three who were on the previous trip. These are Ralph P. Robinson of Merrimac, Mass., assistant; Thomas J. McCue of Brigus, Newfoundland, mate, and Richard Goddard of Winthrop, Mass., sent by the Carnegie Institute to continue the observations in terrestrial magnetism and atmospheric electricity which he began in Baffin Land.

The others are Donald H. Mix of Bristol, Conn., an expert radio operator, sent by the American Radio Relay League, composed of 15,000 amateur operators in the United States; W. F. Lewis of East Lynn, Mass., cook, and John Jaynes of Somerville, Mass., an engineer.

Abram Broomfield, an expert driver of Eskimo dogs, will be picked up at Jack Lane's Bay, near Davis Inlet, Labrador, for his second trip on the schooner.

The "Bowdoin" is expected to reach Etah about August 20. At Cape Sabine the vessel will be allowed to freeze in for the winter, 660 miles from the North Pole.

The principal exploration will be a dog team trip over the ice cap of Ellesmere Land, an elevation of 4,000 feet, and down the other side into Eureka Sound, where big coal deposits which Dr. MacMillan found in 1914 will be investigated.

F. H. Schnell, traffic manager of the American Radio Relay League, announces that WNP (wireless North Pole), the "Bowdoin's" call, will transmit on wave lengths of 185, 220 and 300 meters. Donald H. Mix, radio operator on the "Bowdoin," will stand by from 10 P. M. to midnight for press reports from Arlington; at midnight for reports from NSS; from 1 A. M. to 2:50 A. M. he will communicate with amateurs; 3 A. M. to 4:59 A. M. he will attempt to work stations operating under a limited commercial license, and from 5 A. M. to 7 A. M. he will again try amateurs.

Messages with the prefix "urgent" will be used in emergencies and the amateur receiving such a message will be advised as to its disposition.

The first message from the "Bowdoin" was received at A. R. R. L. headquarters in Hartford, Conn., the day after she sailed. The words sent by Mr. Mix were clearly heard and reported by hundreds of amateur stations.

Before sailing Dr. MacMillan was asked the objects of his present voyage. He is reported as saying:

"The Carnegie Institute again is sending its representative, Richard Goddard of Winthrop, Mass., to make a study of terrestrial magnetism and atmospheric electricity. We also intend to study ornithology, glaciology and botany and to obtain a series of educational photographs of bird and animal life.

"In addition, millions of radio users will be interested in our radio experiment in seeking to keep in constant communication with the outside world through the aurora or northern lights. Many experts have contended that this is impossible. This experiment should eliminate speculation and substitute certainty.

"We hope that our radio experiments and study of atmospheric electricity will help to throw some further light on the effect of atmospheric conditions on radio reception and transmission."

Dr. Donald B. MacMillan, D. Sc., F.R.G.S., the leader of this expedition, was formerly a professor at Bowdoin College and was first induced to go to the Arctic by Peary. He accompanied Peary on the expedition on which Peary reached the Pole and has been back to the Arctic seven times since. Dr. MacMillan was the guest of honor at a dinner given at the Hotel Sherman, Chicago, last spring, by U. J. ("Sport") Herrmann, who incidentally is the owner of the Chicago Radio Show, one of the owners of the Boston Red Sox, and a well known Chicago yachtsman. This dinner was a private affair, attended by prominent naval officers and city officials.

During his talk Dr. MacMillan told of the hardships of the Arctic. He said that the greatest hardship is not, as is commonly supposed, the intense cold—which sends the mercury sometimes as low as 60° below zero—that it is not the privations (for on one expedition which Captain MacMillan commanded he demonstrated that he and his crew could live for a year on nothing but the food which sustains the Eskimo), but that the greatest hardship is the awful solitude—everything going out and nothing coming in. Mr. Herrmann, who from the start has been intensely interested in radio, inquired why he, MacMillan, did not take along a radio set. Dr. MacMillan replied that it would take up too much space. There developed a considerable discussion of just what radio would do, in which discussion Dr. MacMillan became greatly interested. As an outcome he arranged to install both sending and receiving sets aboard the "Bowdoin" and converted the entire forward end of the forecastle into a radio room.

Dr. MacMillan takes with him, installed in the forepart of the ship, a Zenith long distance standard broadcast receiving set with a wave length range of from 150 to 900 meters, and equipped with three-stage amplifier and loud speaking apparatus, as well as a Zenith long wave receiving set with a maximum wave length of 20,000 meters. With these two sets reception will be possible of not only amateur telegraph and phone stations and radiophone broadcasting stations, but also naval and commercial transoceanic stations from which press reports, time signals, weather forecasts, etc., can be secured.

The transmitting equipment consists of a Zenith 500 cycle interrupted-continuous-wave set, using two 250-watt transmitter tubes and the Armstrong regenerative circuit. This apparatus is mounted very compactly in semi-panel form with all necessary meters, and is supplied with current by two gas engine driven Delco generator units entirely separate from the regular power plant of the ship.

The ship's antenna is of peculiar construction, due to the fact that the "Bowdoin" depends for part of its

Radio and the Woman

By Crystal D. Tector

FRIEND HUSBAND has come back from his fishing trip brown as a berry and twice as hungry as he ever was. He collected a store of radio information from the guide who had a wonderful set up in his cabin on the lake. F. H. said that he did not have to even use his little set because "Pop," as he called the guide, happened to be a rabid amateur, with a transmitter and a wonderful receiver. Now nothing will do but for us to get a license and a transmitter and start in to "mess up the ether." Well, you can take it for granted that he will be the only one that uses it, because I have no intention of making our neighbors wish that we were in South America, because of spoiling their evening's DX listen-in.

* * *

He sent me a telegram the day before he left and we both received it two days after he got here. That gave him a great laugh and he said, "Well, supposing that I had been sick and wanted you to come up. I could have passed out before you would ever hear about it." The young fellow that gave it to us, however, explained by saying that it was routed through New Jersey, instead of New York, and landed up in Roselle Park instead of our town, and like a letter it had been floating around until it found us. Wonder if you would call that a magnetic field?

Handy in Warm Weather

WEARING your phones in the warm weather sometimes proves discomforting, due to the heat. This can be alleviated and the wearing of phones made a comfort even in the warmest of weather. The method to pursue in doing this is: Get two rubber sponges at the nearest drug or 5 and 10 cent store. Cut a hole in the center of each sponge and place them on the head set. Then the phones can be worn and the rubber sponge will keep you nice and cool, and prevent the phones from pressing tightly against your ears.

(*Concluded from preceding page*)

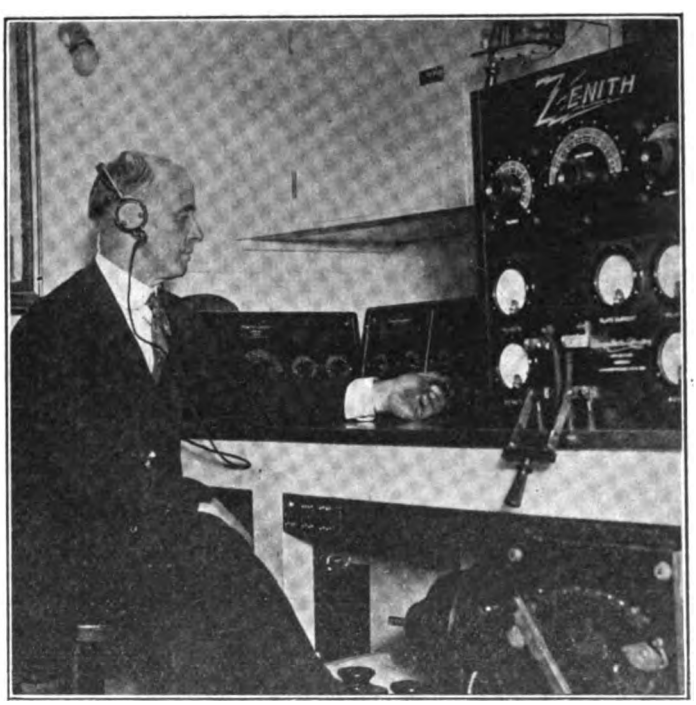
motive power on sails and is of comparatively short length. A stem to stern antenna is used, passing over the main mast and foremast, the lead-in dropping through the foredeck to the radio quarters. In order to insure good ground, steel and copper plates have been riveted to the hull and in addition, connections have been made to the propeller shaft through the engine and to the supply of coal which is carried partly as ballast and for emergency use.

The Government has assigned wave lengths of 200, 300 and 400 meters and has also given permission for Station WNP to use whatever wave length it may find necessary for experimental purposes.

It might be interesting to figure out just how Uncle Sam would move against an ice-bound ship in the Arctic, hundreds of miles from civilization, if its wave length were found to interfere with that of other sending stations!

The American broadcasting station which will be used to send messages to Dr. MacMillan is the new Zenith-Edgewater Beach Hotel Broadcasting Station WJAZ, which incidentally is the most powerful broadcasting station in the country, having 4,000 volts and 10 kilowatt output. This station will not only be used to give Dr. MacMillan and his crew of seven entertainment and news of the day, but it will also be used by the families of Dr. MacMillan and his crew when they desire to send messages to those aboard the "Bowdoin" in the frozen north.

There is a period of 141 days in the Arctic during which a message sent at midnight must pass through hundreds of miles of sunlight before it reaches darkness. It will be interesting to see what effect these peculiar conditions of the Arctic have on radio communication. Up to the present time it has been thought that the so-called auroral band would act as a powerful deterrent in transmitting radio messages. At all events, there is no record of a message ever having been transmitted from the north through it. It will be interesting to learn to what extent the auroral band will interfere, and it is quite possible that scientific data of great importance will be gathered about the Aurora Borealis, which has always been a mystery. Never before have all the amateurs of the country focused their receiving



Dr. MacMillan in the radio room of his Arctic vessel "Bowdoin."

sets upon a single isolated station in the frozen north. It will be interesting to learn what portions of the country receive these messages clearly and what portions do not receive them at all.

Dr. MacMillan on his expedition primarily intends to study terrestrial magnetism. He will also co-operate with the Weather Bureau and Professor V. B. Ekerold, the distinguished Norwegian meteorologist, who helped establish the wireless weather station at Jan Mayen Island off the coast of Greenland.

"Broadcast Central" with Special Land Lines Covers the Country

LOCATED in the heart of New York's musical and theatrical district, where entertainment of the highest order is ever available, "Broadcast Central" offers to the American public the most elaborate radio programs, with a degree of faithfulness in reproduction that marks the beginning of a new era in radio broadcasting. The wires which tower 400 feet above the street on Aeolian Hall, at Fifth avenue and 42nd street, provide two antennas, and this super-station will transmit two broadcast programs simultaneously on different wave lengths.

The closing of station WJZ at Newark, New Jersey, operated jointly by the Radio Corporation of America and the Westinghouse Electric & Mfg. Company, coincided with the opening of "Broadcast Central." The well-known call WJZ was retained for transmission from the Aeolian Hall station on 455 meters, while the call WJY will be used for the other wave length of 405 meters, both of which wave lengths have recently been allocated.

The new station is fitted with a double antenna and

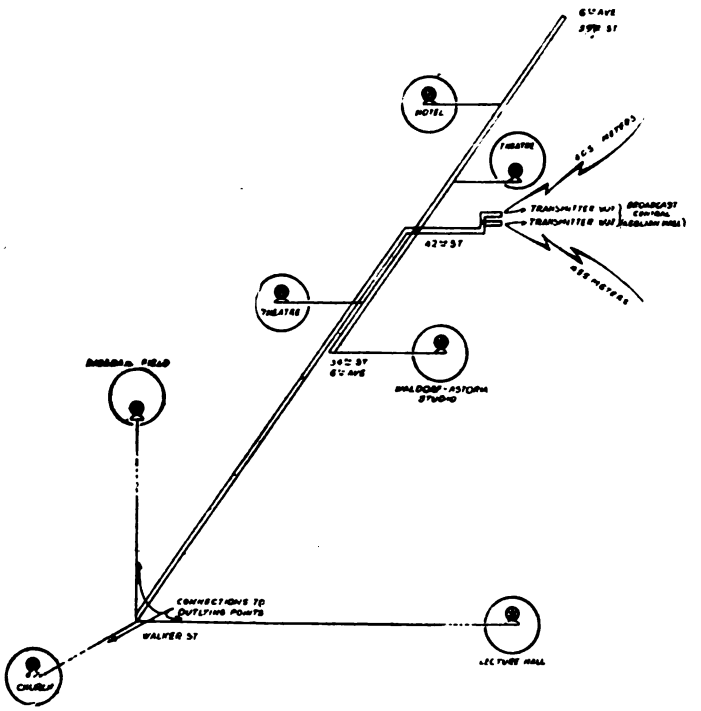

Fig. 1. Outside private cable system of "Broadcast Central" enabling WJZ and WJY to transmit direct from distant points as shown.

two independent transmitters which will permit a dual program to be broadcast; one of classical or serious entertainment, the other of popular airs, dance music and lectures.

The Radio Corporation of America has made a thorough analysis of the types of programs best suited to the requirements of the public and this study has revealed the fact that generally the radio public may be divided into two classes—those who prefer classical or similar entertainment and those desiring dance music and popular airs.

Not only will transmission be carried on from the two studios which are a part of the station, but the main recital hall of Aeolian Hall has been connected to a switchboard in the station thus providing at frequent intervals another source of the finest music obtainable.

To guard against interruption in programs, two spare transmitters are installed together with the necessary controlling apparatus which will enable the operator to make an instantaneous change from one set to another should any trouble develop.

"Broadcast Central" is a model station both in electrical design and operating facilities, incorporating the most advanced ideas of RCA engineers. One of the outstanding improvements is the "checking up" of the broadcast programs for clearness in transmission. This is accomplished by a "moving picture" device con-

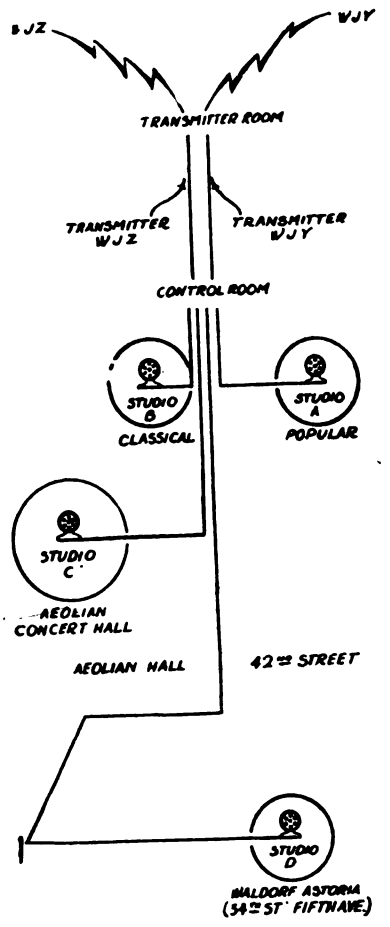

Fig. 2. Studio system of "Broadcast Central." The two studios located on the sixth floor of Aeolian Hall, the studio of the concert hall and that of the Waldorf-Astoria are all connected by private cables and can be plugged in from the control room.

nected with the antenna which shows at a glance the perfection in reproduction of music or voice as the radio waves leave the antenna. Any distortion occurring during a rendition may be instantly corrected by the operator who watches the electrical vibrations as they radiate into space.

The following summary of outstanding facts about "Broadcast Central" will be of interest:

Call Letters: WJY designates the 405-meter transmission, while WJZ designates the 455-meter transmission.

Location: Heart of New York's musical district where the finest of entertainment is ever available. (29 West 42d St., N. Y. City).

Towers: There are two self-supporting steel towers erected on the roof of the building. They are each 115 feet high and their total weight is 15 tons.

Who's Who in Radio Inspection

EVERY amateur and broadcaster should know the officials of the Radio Section of the Department of Commerce in his district, so that he can get advice, keep in touch with new regulations and not be imposed upon by bogus representatives.

At headquarters in Washington, Chief Supervisor of Radio W. D. Terrell is in charge under Secretary Hoover and Commissioner Carson. Mr. Terrell is assisted by W. E. Downey, Supervisor of Radio. In the nine districts with headquarters as shown, the following men are in charge:

District	Headquarters	Supervisor of Radio
1st	Boston	C. C. Kolster
2nd	New York	Arthur Batcheller
3d	Baltimore	R. Y. Cadmus
4th	Atlanta	R. Y. Cadmus (until relieved by Van Nostrand)
5th	New Orleans	Theodore G. Deiler
6th	San Francisco	J. F. Dillon
7th	Seattle	O. R. Redfern
8th	Detroit	S. W. Edwards
9th	Chicago	E. A. Beane

Some recent changes in the personnel of the districts have been made. A. F. Parkhurst, Assistant Radio Inspector at Detroit, has been transferred to the 9th District at Chicago. Assistant Inspector H. S. Pyle has been appointed to work in the Detroit office, replacing Mr. Parkhurst. Assistant Inspector L. E. Richwien, of the Baltimore office, has been detailed to the 7th District at Seattle. It is planned to open the office at Atlanta as the headquarters of the 4th District soon, and Radio Inspector Wallis Van Nostrand, Jr., now at Norfolk, will probably be designated as supervisor of this division.

Radio Interference Disappearing

OFFICIALS of the Department of Commerce report that the schedule of new wave lengths for broadcasting stations has met with a cordial reception throughout the country, and that improvement in reception is noted almost everywhere.

All nine Radio Supervisors report satisfactory results in the allocation of the Class B and A wave lengths, stating that almost all listeners-in are experiencing better reception than ever before in summer time, even with atmospherics at their height. Last summer they point out some five hundred stations were operating on 400 and 360 meters, whereas today the B stations have some nearly 40 exclusive national waves, and the A stations have thirty-one waves assigned individually in the nine radio districts.

The real success or improvement brought about by the wave allocation will not be fully appreciated until later in the fall.

Over three hundred of the old stations continue in Class C, satisfied apparently to operate on 360 meters. Experts of the department express some surprise at this condition; they hoped for early applications for transfers to Class A and B with independent wave lengths. Although no new stations are being licensed under Class C the fact that over three hundred stations, scattered all over the country, continue to transmit on the 360 meter wave tends to maintain interference which it was expected would be eliminated to a greater degree.

A member of the radio section pointed out to the writer that if the radio receivers would use shorter, single wire antenna and listen in on the shorter wave Class A stations, some atmospherics would be eliminated. Reception should be better. The use of loops and indoor aerials is also recommended.

(*Concluded from preceding page*)

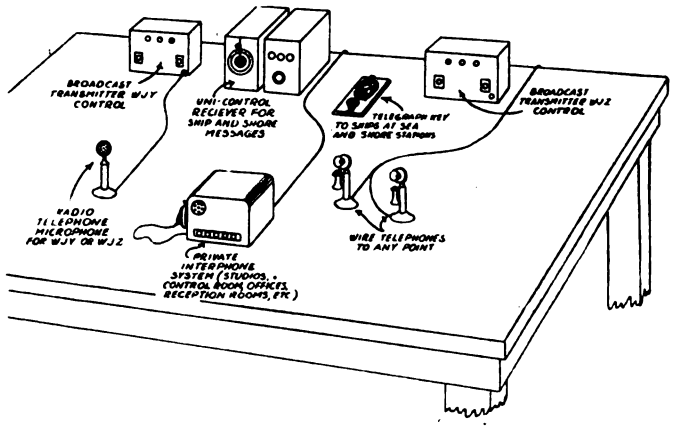
Antenna: Consists of two independent sections supported between towers. Height above street level is 350 feet. The two sections of wires have individual "lead-ins" to the transmitting house on the roof.

Wave Lengths: Each section of antenna is energized by an individual transmitting set permitting a double programme to be broadcast on two wave lengths without mutual interference. This combination of two independent aerials with associated equipment permitting simultaneous broadcasting is an exclusive feature of "Broadcast Central."

Studios: One studio has been provided for each transmitting channel, one for classical music, the other for popular airs, lectures, etc. In addition, special wires are installed from the main recital hall of the building direct to transmitting house on the roof. On certain occasions special events or recitals will be broadcast direct from this large hall.

Emergency Equipment: For each channel there are two complete transmitting sets. These spare sets may be connected into the circuit of each antenna by the simple manipulation by a switch. This provision will prevent any interruption of programmes through the failure of any transmitting set.

Device "Checks Up" Programme Broadcast: A new device inserted in the antenna circuit of each channel indicates the clarity of transmission. The operator in charge can, at a glance, actually observe the degree of perfection in the reproduction of a programme. A switchboard near this instrument enables the operator to correct any distortion in transmission that may occur.



BROADCAST TRANSMITTER WJY CONTROL
UNI-CONTROL RECIEVER FOR SHIP AND SHORE MESSAGES
TELEGRAPH KEY TO SHIPS AT SEA AND SHORE STATIONS
BROADCAST TRANSMITTER WJZ CONTROL
RADIO TELEPHONE MICROPHONE FOR WJY OR WJZ
WIRE TELEPHONES TO ANY POINT
PRIVATE INTERPHONE SYSTEM (STUDIOS, CONTROL ROOM OFFICES, RECEPTION ROOMS, ETC.)

Fig. 3. Transmitter room communication table at "Broadcast Central." This is the "heart of the station" as it is from here that the control of both stations is covered. Each station has two channels through which it transmits, and both are controlled from this table. Here the chief operator sits and regulates the transmission at the same time listening in on ship length so as to be able to shut down immediately in case of an SOS.

The Heart of "Broadcast Central": The control equipment located in the transmitting room on the roof is the heart and nerve centre of the system. The operators have before them a microphone through which they can talk by radio telephony, a key by which they can converse in dot-dash telegraphy and telephone equipment which provides communication with any point in the United States. An inter-communication system provides for internal communication between studios and transmitting room.

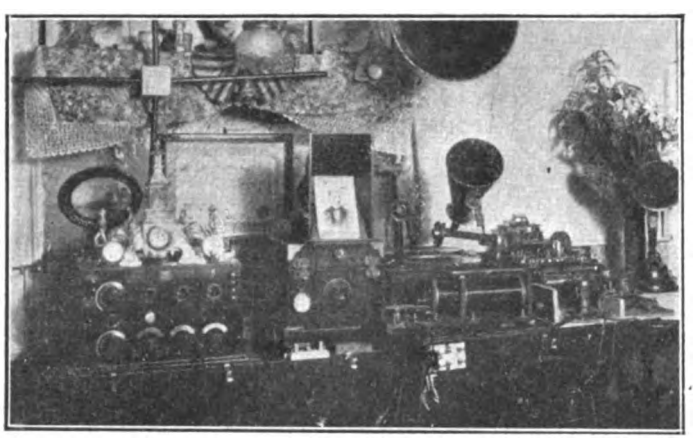
RADIO PRIMER

INTERFERENCE. One of the common troubles experienced by the radio fan these days is interference. It is experienced mostly by the single tube sets, or crystal sets. This is because of the fact that neither of these two types is capable of very sharp tuning.

To illustrate tuning and interference and what is meant by it, it is best to depart from radio principles and go back to elementary physics.

If we take two musical instruments, such as two violins, and tune each of them exactly the same, we can cause one to vibrate independently by simply plucking a string of the other or drawing the bow across one of the strings. This is because when we pluck one of the strings it vibrates and causes the surrounding air to vibrate. The second string picks up these vibrations, and vibrates with them. Now if we place our finger on the string and shorten it, and pluck



Impressive station of James F. McEvoy, 37 Fourth Street, New Brighton, Staten Island. He started in last July with a simple crystal set and now is the possessor of numerous sets, including a three stage R. F. set for loop work.

the string again, we will find out that the second violin will not vibrate. We have shortened the string, causing it to give out vibrations of much shorter length and higher speed, and they do not affect the second. That illustrates sharp tuning.

Now if we take a third violin and tune it the same as the other two, we can cause the second violin to vibrate from two different sources. If we take the first violin and cause it to send out intermittent vibrations by stopping and plucking its string, the other two will vibrate intermittently in unison. If we cause the first and third violins to vibrate, the first violin intermittently and the third continuously, the second one will vibrate continuously, due to the fact that the third one is interfering with the vibrations of the first and all three being tuned the same they all respond to the same note or wave length.

Now if we carefully tune the first two just a little bit higher or lower, we can cause either one of them to vibrate in unison by plucking them, and at the same time the note from the third will not have any effect on them. The reason is that they now do not respond to the same vibrations as the second and therefore no interference is caused.

A radio set is practically the same. If two stations are transmitting on the same wave length or frequency, a third station that is receiving will hear them both, and because they are both transmitting on the same wave he will be unable to hear either one distinctly on account of his receiver responding to the ether vibrations of both at the same time.

If we therefore lower the wave length of one of the transmitters it is then possible for the third station to pick either one at random—if the receiver is capable of sharp tuning. A crystal set will pick up signals over a fairly broad band of wave lengths, and while it may receive one a good deal louder than any of the others, it is still possible to hear the others when the strong station pauses or stops.

A great deal of the so-called interference would be stopped if the owner of a receiver learned to tune it properly, or if it is a single circuit receiver it can be stopped or decreased by the use of a shorter antenna or energy collector.

Methods of decreasing interference. A lot of interference can be eliminated at the receiving end. That is, of course, when reception is desired from stations that are not on exactly the same wave length. If two stations are both transmitting on the same wave length tuning is impossible. But where one station is higher than the other, and signals from both stations are heard at the same time, it is possible in most cases to eliminate one and only hear the other.

As before stated, the shortening of the antenna to around 80 feet will help. Then the amount of wire used in the wiring of the receiving set should be as short as possible.

A lot of receivers do not use tuned secondaries, or ticklers. If the tickler or secondary is tapped at about half its usual value and a two bladed shorting switch used, it will help the tuning immensely. Then along the same method, if instead of a single blade switch being used for the primary or antenna tuner a double blade switch is used and fixed in such a manner that it will short two of the following sections of unused wire, it will eliminate dead end effect and accordingly sharpen the tuning of the receiver. The use of extra capacity in any of the circuits should be omitted as far as possible, and where a circuit does not call for condensers, nothing can be gained by their use. Fixed condensers should never be used across inductances that are used for tuning as their use broadens the tuning considerably, sometimes to such an extent that tuning is practically impossible.

Three New Class A Stations Licensed

THREE new Class A Broadcasters were licensed by the Department of Commerce during the past week, and seven stations were transferred from Class C on 360 meters to Class A status.

New Class A Stations

Call	Station	Meters	Kcys	Watts

New York Department Store Broadcasts Musical Comedy

RADIO fans had the opportunity of hearing a unique musical comedy on the night of June 28, when "Once Upon a Time," written and produced by employees of R. H. Macy & Co., Inc., New York City, was broadcast from Station WJY. The performance was given on the 405 meter wave length.

Richard Barriscale, brother of Bessie Barriscale, film star, is the author of the play and its hero. A number of tuneful songs written by Jack Straus, son of the president of Macy's, Ralph Goldstein, and Mr. Barriscale were rendered, among them: "When You Smile," "Hearts Are Trumps," "Hitch Your Wagon to a Red Star," "He's Getting Better Day by Day," "You'll Think of Me Sometimes," "May-Ga-Lanka Blues," and "Macy Mine."

The operetta was originally produced last month at the Central Opera House under the auspices of the Community Club, an organization of Macy employees. A great deal of attention was attracted to it at the time by the Beauty Chorus, whose pictures were later featured in newspapers throughout the country.

Another hit was a burlesque on the Floradora Sextette by six husky delegates from the store's delivery department, who donned ballet costumes to lend an air of realism to their performance.

One of the comedians heard in the broadcasting was Guy Somers Mitchell, who was formerly in vaudeville with the song and dance team of Somers and Le Grand. Mr. Mitchell took the part of the Sphinx of Gizeh.

The play was condensed for broadcasting purposes by Miss M. C. Sidney, head of Macy's Department of Training, who was formerly on the stage. Mrs. V. C. Sidney, her mother, who is one of the characters of the play, had a long theatrical career under the stage name of Vida Crowley. During the war she was in France with the Y. M. C. A. canteen service.

Miss Kathleen Graelish, who played the double part of Sally and Irene, has been heard over the radio before. So has William Francis. Both collaborated in the Christmas stories sent out by WJZ.

Frank Logan, assistant radio buyer at Macy's, coached the characters on the essentials of a good broadcasting voice. Miss Phyllis Reid assisted Miss Sidney in the rehearsals. Musical numbers were rendered by Julius Lenzberger's orchestra.

Guy Somers Mitchell and some of the girls from R. H. Macy's "tuning up" before broadcasting the play "Once Upon a Time" from Station WJY, New York. The entire production was written and staged by employees of R. H. Macy & Co., New York City.

Summer Tips to Summer Fans

By R. L. Dougherty

NOW that the season has started and many amateurs and fans have packed their radio sets into trunks or constructed portable sets to take on their cars or up to their camps, a lot of funny troubles will arise that will seem to have no solution and will tend to discourage the fan.

These little troubles are of such nature that they will sometimes mystify you, even though they may not seem to have any direct bearing on the receiver's range. The first and foremost of these troubles will be noticed when the receiver will respond only to signals from one direction and "lay down" on the station that is supposed to be the strongest in the section. "Why, I can't even get a peep out of XYZ, and yet I get that weak station ZYX O. K.," will be the sad story. Well, the reason for this is that there is some condition in the surrounding country that is causing the signals of one station to be absorbed whereas the other station is not bothered. A look around the country will generally reveal a heavily wooded hill or a forest which is causing the trouble. This cannot be remedied without moving the location of the set to the other side of the disturbing factor, and when that is done, no signals will be received from the opposite direction, due as before to certain signal absorption.

The next and most troublesome aspect will be found when a ground is wanted. If you are camping, near a stream of course a good ground will be perfectly easy, or if you are using a loop receiver it will not bother you at all, but in cases where it will seem that you have a perfect ground, your set will sometimes act peculiarly, and the tuning will be extremely sharp, too much so for comfort, and the signals will be weak and unsteady. If after a heavy rain the signals are noticed as increased and the tuning nearer to normal, you will know that your ground, no matter how good it looks is poor. A good way in which to assure yourself of a positive ground is to dig a small hole about a foot wide and three or four feet deep. Into this place on the bottom a layer of soaking wet charcoal, ashes or anything that will hold moisture. Then take the ground wire and solder it to an old tin can, which you have first soldered to a piece of tin or old iron. Place this in a hole and pour plenty of water around it—fill the hole up a couple of times with water and let it soak into the ground. Then put more damp earth or earth and charcoal around it and leave it alone, except for keeping it soaking wet all the time.

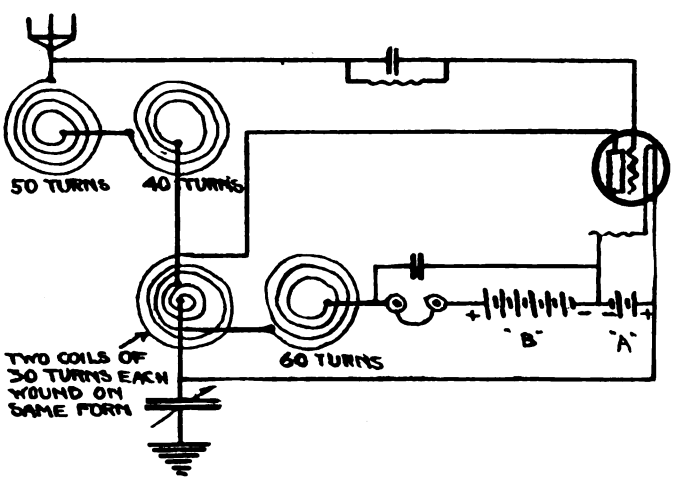
Homemade Sets for the Government Lighthouse Service

By Arthur G. Shirt

PLANS for a complete radio receiver and instructions for building it have been issued by the Bureau of Lighthouses, Washington, D. C., for the information of the Field Employees of the Lighthouse Service. The receiver was designed by Mr. A. W. Tupper, Assistant Engineer of the Bureau, and was developed mainly along the lines of simplicity and ease of construction, sacrificing nothing, however, which would tend to make it more efficient. Mr. Tupper spent several months investigating a number of the simpler forms of regenerative circuits published in the many radio magazines before he evolved the set which he now recommends. The results of his investigation have been published in a Departmental circular, have been supplemented with blueprints, and are now ready for distribution to the lighthouse keepers and to others in the service who have evidenced their interest.



Circuit diagram of the lighthouse set. There are four spiderweb coils used. The one in the plate circuit has two windings, as shown, to supply feedback.

The set recommended is a single circuit regenerative receiver which makes a somewhat novel use of two spider-web variometers. One variometer is used to vary the inductance in the antenna circuit, while the other not only tunes the plate circuit, but also secures regeneration by acting as a feedback inductance. This novel effect is obtained by winding an extra antenna inductance of 30 turns on the primary form of the plate variometer. Inductance is thereby set up between the antenna circuit and the oscillating circuit, varied by the movable secondary of the plate variometer.

This particular arrangement was finally decided upon as being best suited to a homemade set for the following reasons: The instruments involved are easily constructed from materials that are readily obtainable. The parts which must be purchased are inexpensive, excepting, of course, the detector tube and headphones. There are no critical values of the various parts which must be tested and adjusted until an ideal arrangement is obtained. The tuning is simple. The signals are loud and clear when there is no interference, and for a single circuit the selectivity is very good.

Six or more of these sets have been constructed in the course of testing the circuit, and the results obtained from them have been consistently satisfactory. While being tested in Washington, concerts were picked up from Boston, Chicago, Detroit, Kansas City, Atlanta, Davenport and sometimes Havana, Cuba. The number of turns on the various coils has been determined by actual tests and they are adapted for use with antennae in the neighborhood of 100 feet in length. The tubes recommended are of the dry-cell variety, and the cabinet is constructed so that the batteries incidental with such tubes are hidden from sight in a compartment at the base of the set. There is room in this compartment for storing an extra dry cell. The instructions contained in Circular Letter No. 2, which describes the set, are written in plain, non-technical language, and are complete in every detail.

The Panel

The panel should be a piece of close-grained wood ¼-inch thick. Before placing in the cabinet lay out all holes, taking measurements from blueprint, which is one-half actual size. Put rheostat and condenser in place to be sure the holes are in the proper places, then remove instruments and put panel in the oven and heat thoroughly to drive out all moisture, but be careful not to scorch. While panel is still hot, give it a thorough coat of thin shellac on both sides and all edges and in the holes. Let dry for 24 hours and give it two more coats of shellac at least 12 hours apart. *Do not paint this panel with ordinary paint.* If a color is desired, stain the panel with a spirit stain or water color stain before baking.

After the third coat of shellac is dry, cover the inside portion of the panel that is above the shelf with tin-foil, which may be stuck to the panel with shellac. While the shellac is still soft, scrape the tin-foil away from around all holes through the panel, so that no metal parts of condenser, rheostat, binding posts, or any of the wiring or wire terminals will touch the tin-foil.

Making the Grid Leak

Take a piece of photographic film (or heavy paper, if no film is obtainable) and cut it to the size of the grid condenser, making a hole in each end to correspond with the holes in the condenser where the connection wires are attached as previously described. Thoroughly roughen the surface of the film with sandpaper (after scraping off all traces of any picture which may have been on it) and with a soft pencil make a heavy wide mark around both holes, and draw a heavy pencil line from one hole to the other, then secure this to one side of the grid condenser by the screws with which you make the wire connections, being sure that the head or nut of each screw touches the pencil mark you made around each hole. After you have succeeded in tuning in a station, try out the grid-leak by making the pencil lines heavier or erasing them partly until the clearest and loudest signal is obtained. The amount of this grid-leak depends on the qualities of the detector tube, some tubes requiring no grid-leak at all, others requiring a heavy, broad pencil mark.

The instructions for constructing and erecting antennae and for making ground connections are furnished on a separate sheet. Four blueprints accompany the present circular, showing in detail how the apparatus is assembled and wired, as well as the methods of winding the spider-web coils. No provision is made for the addition of one or two steps of amplification, that being left to the skill and other requirements possessed by employees of the Lighthouse Service.

This Crystal Detector Set Has Many Advantages

By Ervin J. Trojan

[The set described below, says the author, has been thoroughly tested and found worth while and its merit proved by public approval. Large numbers of these sets are in use in Chicago and are giving satisfactory service.—Editor, RADIO WORLD.*]*

DURING the early part of 1921, when radiophone broadcasting first appeared, development of receiving sets was pushed feverishly; so feverishly indeed, that some devotees of the ether waves were neck-deep in superregenerative sets and other highly complex circuits before they even realized that a simple crystal detector would also receive radiophone signals.

Of course, a crystal detector set will not receive long distances and its output of sound is limited. But where such a set can be used within 15 or 20 miles of a moderately powerful broadcasting station, these drawbacks are very slight. And deep down in our inner consciousness we might even concede that a local concert, heard over a good crystal set, will sound better than one a thousand miles away, heard over an engineering marvel, but slightly mixed with interference and fading.

For the novice who wishes to begin enjoying the pleasures of ether-borne music, or for the person who wishes to make his first set, a crystal detector set is recommended. It will not cost much, it is sure to work, and it will serve as a stepping stone to the more complicated and expensive sets. The initial cost of such a set is very low; its upkeep is nil; it is simple to construct and to operate; it is non-interfering and all but insensible to static; for clarity of tone it has no superior.

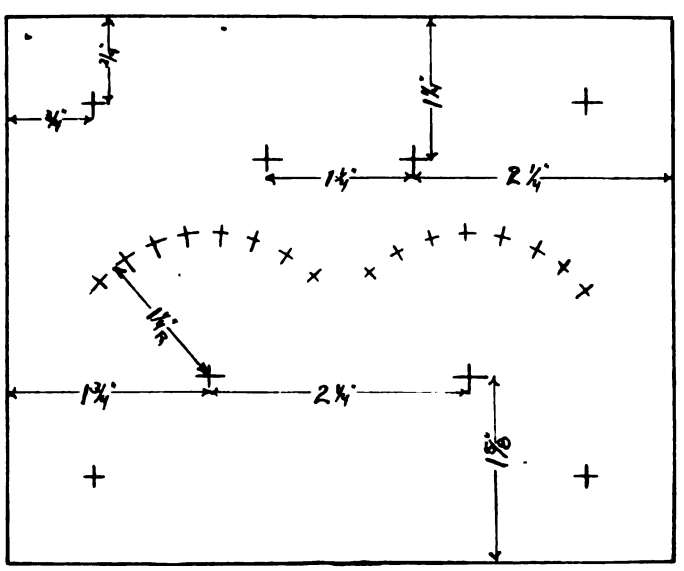

Fig. 1—Panel layout for an efficient crystal set.

The writer will describe a small crystal detector set which has proven very popular, largely because of its pleasing design, low cost and efficiency. The complete set is about the size of an ordinary book, and has but three controls—adjustable crystal detector, coarse and fine tuning switches. The wave length range with a 60 foot aerial is approximately 300 to 500 meters.

The material required for the construction of this set will be as follows: ¼ inch whitewood, two pieces each, 1¼ inch by 5 ¾ inch, 1¼ inch by 4¼ inch, 4¾ inch by 5¾ inch; 4 binding posts; 2 switch levers, 1¼ inch radius; 1 crystal cup; 1 detector stand; 1 radiocite crystal; 12 contact points; 4 switch stops; 2 oz. No. 26 D. C. C. wire.

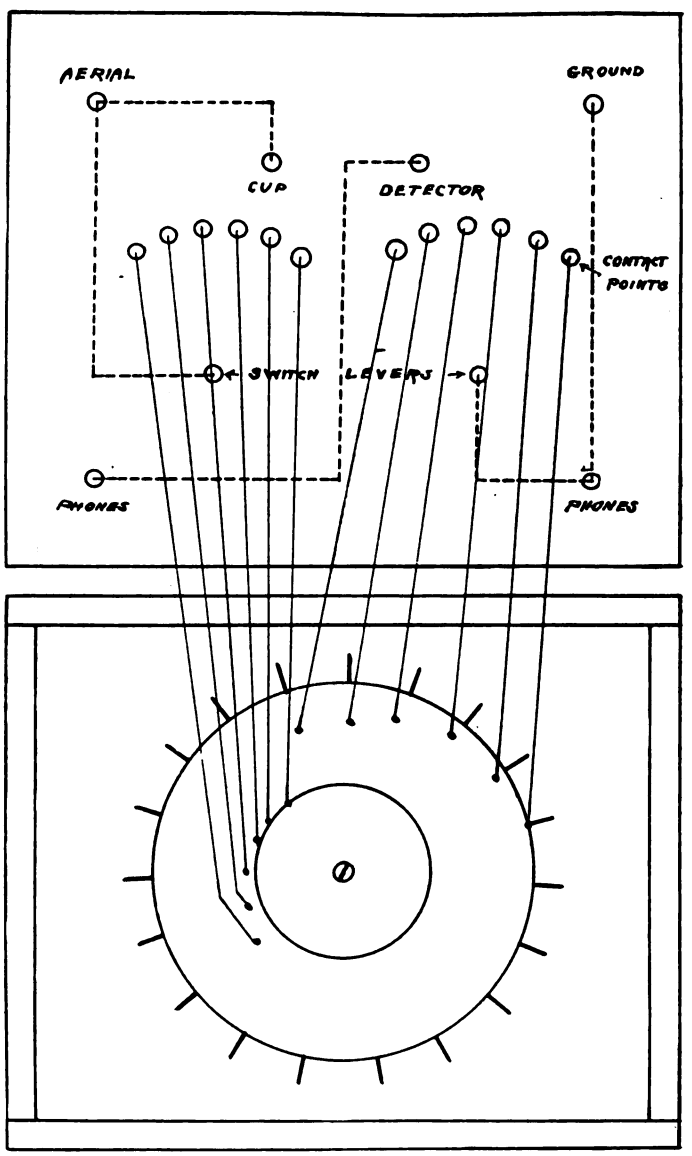

Fig. 2—Arrangement of instruments inside cabinet.

Drill one of the large pieces of wood, which will be the panel, according to Fig. 1. Construct the box as in Fig. 2, gluing and nailing all joints except the panel, which should be fastened temporarily with four small brads. Sandpaper well, stain to the desired color and apply at least two coats of varnish or shellac. Then remove the panel and assemble the various parts on it. After assembly the panel should be wired from

WORLD NEWS HAPPENINGS BRIEFLY PHRASED FOR OUR BUSY READERS

The automobile industry set a new production record in May by turning out 350,180 passenger cars and 42,983 trucks, according to figures from the Department of Commerce. Now let's see that they're all radio equipped!

* * *

Dr. W. R. Whitney, director of the research laboratory of the General Electric Company, was recently elected a member of the corporation of the Massachusetts Institute of Technology for a term of five years. He was graduated from the institute in 1890.

* * *

Station WOR, operated by L. Bamberger & Co., Newark, N. J., has arranged to have the New York *Morning Telegraph* broadcast, every Monday evening, its moving picture news and reviews. The series of talks, which will be called "Current Motion Pictures," is scheduled to begin on the evening of July 9.

* * *

Boy Scouts of America National Council, consisting of 1,300 representative business and professional men from all parts of the United States, will hold its thirteenth annual meeting on July 8 and 9 at Palisades Interstate Park, New Jersey. It is expected that Station WEAF will broadcast the proceedings and activities of July 9 to the whole country.

* * *

Dr. Lee De Forest, inventor of the phono film and manufacturer of radio equipment, returned from Europe last week with the impression that English newspapers were boycotting the broadcasting of news items and that members of the British theatrical and musical professions were opposed to radio broadcasting. He pointed out that there were but eight broadcasting stations in England and that the government had declined to issue any more permits.

Station WHAH, operated by Hafer Supply Company, Joplin, Mo., is now working on 250 watts.

* * *

Dr. Samuel Wesley Stratton, president of the Massachusetts Institute of Technology, Cambridge, Mass., received the honorary degree of Doctor of Laws from Harvard University at the recent annual commencement.

* * *

A correspondent of WGY who has beautiful faith in the efficacy of radio in the capture of criminals, recently requested the General Electric Company station to announce that a reward of $50 would be paid for the arrest of the "parties" guilty of chipping words off the family grave stone.

* * *

College students are working in the places of striking shop craftsmen in the Olean, N. Y., shops of the Pennsylvania Railroad. The students are from Purdue University, Pennsylvania State and Ohio State universities and technical schools. They are studying engineering, and went to Olean for practical experience. The railroad has asked the colleges and universities by radio for men seeking work in the courses they are studying.

* * *

All records for wireless transmission and reception were broken on the recent trial trip of the S.S. "Leviathan." On the last of the five days' run the four radio operators—Lieut. John R. Irwin, Elmo N. Pickerill, Anthony Tambourino and Raymond J. Green—were about exhausted. General Manager David Sarnoff, of the Radio Corporation of America, who was one of the guests aboard and who began his radio career at the key, jumped in and helped in transmitting, easing the strain on his men.

(*Continued from preceding page*)

underneath, as shown by the dotted lines. The schematic diagram appears in Fig. 3.

The tuning inductance used is popularly known as the "spiderweb." This form of winding has perhaps the lowest distributed capacity of any. Here it might

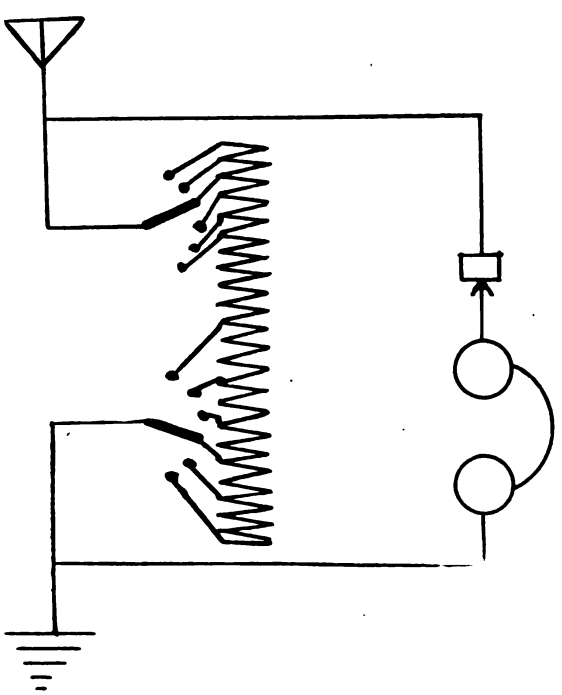

Fig. 3—Circuit diagram of receiver of Trojan's crystal set.

be advisable to add that no tuning inductance, of whatever form, should ever be coated with any varnish, shellac or cement. These substances all have a higher specific capacity than air, and will impair the efficiency of the coil. The spiderweb is made by cutting out of heavy pressboard or 1/32 inch fiber two disks, each 1½ inch in diameter. Lay one of these disks on a flat surface and space on it radially 19 wooden spokes, 1/16 inch in diameter by 2 inches long. A round type of hardwood toothpick answers admirably for this purpose. Pour glue over the ends on the disk, and place the other disk on top. Place a heavy weight on the finished form and let dry. This makes a winding form of ample rigidity and light weight. To wind the coil, make a reference mark on the tip of one of the spokes, and starting at that spoke, weave the wire in and out between the spokes, skipping two spokes at a time. When twice around make a loop in the wire about ⅛ inch in diameter. Wind two more turns and make another loop. Repeat until five loops have been made. This constitutes the fine adjustment. Now wind twenty turns, and make a loop. This is the body of the coil. Next wind eight turns and make a loop. Repeat four more times, but instead of making the last loop, cut off the wire. This constitutes the coarse adjustment. The coil should now have six taps at the inner end, and six taps at the outer end. Fasten this coil inside the box to the bottom with a small brass screw, and solder short wires from the taps to the contact points on the panel, as shown. See that these lead wires do not touch each other, and fasten the panel to the box permanently.

The crystal recommended is tellurium sulphide, better known by its trade name of "Radiocite." It is not quite as sensitive as a good crystal of galena, or lead sulphide, but it is more reliable and will give satisfactory results. Always handle the crystal with forceps; handling with the fingers will deposit oil and perspiration on the sensitive surface of the crystal and impair its usefulness. Should this happen, however, the crystal can be cleaned with alcohol or soapy water. Crystals should not be mounted in lead or low melting solder, as any heat much above body temperature will injure them.

This set, if properly constructed, will give as good results from local stations as a simple vacuum tube detector.

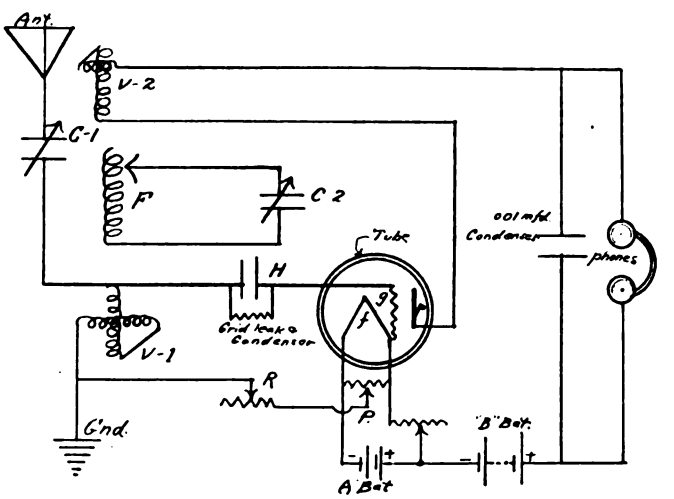
A Combination of Two Methods of Regeneration

By C. White, Consulting Engineer

BEFORE I start this article I want to thank the many amateurs who have written to me concerning my super amplifier, and I want to say that all letters will be taken care of in the proper way. I greatly appreciate the confidence my readers have placed in me and I shall be glad to perform a similar service for them whenever it is necessary. There are many surprises in store for you along the radio line. I am working up several new things in my laboratory at present, and as soon as I can get the goods in the hands of a reliable manufacturer and working in a commercial way, I shall write up some new applications and circuits. When anything new appears in my articles in the way of radio parts and you can not obtain them readily in your locality I am always willing to put you on the right track if you will address me in care of RADIO WORLD and enclose return postage. Many letters have come to me recently from radio dealers, and I want to welcome this type of correspondence.

The circuit to be taken up in this article is a modification of a circuit published under my name not so long ago. The improvement consists in the substitution of variometers in place of tapped and immovable coils. This addition goes far to make the circuit more effective and efficient in tuning. In reality there is a combination of two types of regeneration—namely, the two variometer feed back method and the electromagnetic tickler coil arrangement. Then again, a resistance R is inserted in the filament-grid circuit of the detector tube and is very effective in controlling regeneration with the new UV199 tube. The potentiometer P permits shifting from the positive to the negative side of the filament to obtain the best results. Some claim that the new tube works much better when it is connected up to the negative side of the filament on the grid return, while the manufacturers and others claim just the reverse. Personally I have found that in the majority of cases the negative side gives a little better results than the positive. The potentiometer P permits you to try either condition without disconnecting anything. The resistance R and the potentiometer P should each have a resistance of 400 ohms. In order to cut down noise in adjusting and tuning with these resistance units it is better to use a carbon pile type of rheostat or potentiometer although from the theoretical standpoint a wire type will work just as well. The condensers C-1 and C-2 are air variables having 23 plates apiece. A vernier attachment on both condensers is recommended. The coil F consists of 60 turns in all with the last 300 turns tapped for every ten turns for switch points and, if it is so desired, more frequent tapping of the coil can be resorted to, although three taps will suffice. The variometers V-1 and V-2 are nothing more than the ordinary standard type of short wave variometers.

The theoretical action of this circuit can be briefly surveyed as follows. The incoming signal impinging on the antenna is tuned in through the circuit composed of the condenser C-1 and the variometer V-1. The signal current flowing in the tuned circuit produces a voltage drop across V-1 which is picked off by the filament-grid circuit of the detector tube for detection or rectification. The grid leak and grid leak condenser H help to make the tube action correct and greatly aid detection. Energy is fed back to the tuning circuit by means of the variometer V-2 in the plate circuit and the circuit composed of the coil F and the condenser C-2. This backward transfer of energy helps to compensate for the resistance of the tuning circuit and thus causes a large amount of current to flow in if, hence increasing the voltage drop across V-1 and the signal becomes many times stronger than if regeneration is not used. The reason for the use of the circuit F and C-2 is that although regeneration is possible by means of two variometers alone still it is almost next to impossible to tune and hold the regenerative point without causing the tube to spill over and oscillate. By this new method we can approach regeneration by means of



Circuit diagram of a very selective and easily controlled receiver.

the variometer V-2 and we can hold or adjust to more critical or super-regeneration by tuning the circuit F and C-2. The core on which F is wound should be about four inches in diameter and should be placed between the two variometers. It should be wound with No. 22 D.C.C. magnet wire and, figuring 20 turns to an inch of tube length, then about four inches of tubing will be needed.

To successfully construct this tuner much experimental or cut and try work must be done. If regeneration is not obtained the variometer connection V-2 should be reversed or the coil F should be turned around the other way. Try reversing each separately and both together and note the results of each trial. You will observe that one particular combination is much superior to all the others. It is far better and more certain to try out your connections in this manner than to rely on any set rule of direction of windings or the like. Then again, you learn far more by trying things out for yourself to a certain extent than by blindly following some set rule of thumb method. But there are some little precautions or tips that will help to make your set just a little better. For instance, the movable plates of the condenser C-1 should be connected to the antennae and the fixed plates to the grid or V-1 side. By so doing you will greatly diminish body capacity in tuning and the circuit will not howl when you touch the condenser dial.

Five watt A. C. Transmitter built by E. Wilbur, a New York amateur. By simply plugging a double wire into the light socket it is possible to operate this set on C. W., I. C. W. or phone. Both filament and plate current are supplied by the transformer on the extreme right.

First Wartime Radio Code Drafted

INTERNATIONAL rules for the control and operation of radio in time of war, as propounded by the Commission of Jurists at the Hague, have been announced by the Department of State.

These regulations, in the preparation of which Capt. Samuel W. Bryant, U. S. N., and Col. Geo. S. Gibbs, U. S. A., assisted American Commissioners Moore and Washburn, provide substantially that:

In time of war the working of non-belligerent radio stations shall continue to be organized, as far as possible, in such manner as not to disturb the services of other radio stations. Belligerent and neutral powers may regulate or prohibit the operation of radio stations within their jurisdiction.

The erection or operation by a belligerent power of radio stations without neutral jurisdiction constitutes a violation of neutrality on his part as well as on the part of the neutral power.

A neutral power need not restrict or prohibit the use of radio stations located within its jurisdiction, except to prevent the transmission of information destined for a belligerent concerning military operations and except as further prescribed. All restrictive or prohibitive measures taken by a neutral power shall be applied impartially by it to the belligerents.

Belligerent mobile radio stations within a neutral state must abstain from all use of their radio apparatus. Neutral governments are bound to prevent such use.

The transmission by radio by a vessel or an aircraft, whether enemy or neutral, when on or over the high seas, of military intelligence for the immediate use of a belligerent is deemed a hostile act and will render the vessel or aircraft liable to be fired upon. A neutral vessel or neutral aircraft which transmits, when on or over the high seas, information destined for a belligerent concerning military operations shall be liable to capture. The Prize Court may condemn the vessel or aircraft, if it considers that the circumstances justify condemnation. Liability to capture of a neutral vessel or aircraft on account of the acts referred to is not extinguished by the conclusion of the voyage or flight on which the vessel or aircraft was engaged at the time, but shall subsist for a period of one year after the act complained of.

In case a belligerent commanding officer considers that the success of the operation in which he is engaged may be prejudiced by the presence of vessels or aircraft equipped with radio installations in the immediate vicinity of his armed forces or by the use of such installations therein, he may order neutral vessels or neutral aircraft on or over the high seas; to alter their course to prevent their approaching the armed forces under his command; or not to make use of their radio transmitting apparatus while in the immediate vicinity of such forces.

A neutral vessel or aircraft, which does not conform to such direction, exposes itself to the risk of being fired upon. It will also be liable to capture, and may be condemned by the Prize Court.

Neutral mobile radio stations shall refrain from keeping any record of radio messages received from belligerent military radio stations, unless such messages are addressed to themselves. Violation of this rule will justify the removal by the belligerent of the records of such intercepted messages.

Belligerents are under obligations to comply with the provisions of international conventions in regard to distress signals and distress messages so far as their military operations permit. Nothing in these rules shall be understood to relieve a belligerent from such obligation or to prohibit the transmission of distress signals, distress messages and messages which are indispensable to the safety of navigation. The perversion of radio distress signals and distress messages prescribed by international conventions to other than their normal and legitimate purposes constitutes a violation of the laws of war and renders the perpetrator personally responsible under international law.

Acts not otherwise constituting espionage are not espionage by reason of their involving violation of these rules. Radio operators incur no personal responsibility from the mere fact of carrying out the orders which they receive in the performance of their duties as operators.

Inter-Continent Relay by North Pole Radio

HARTFORD, CONN.—The expedition to the Arctic in charge of Dr. Donald B. MacMillan will keep in touch with all civilized countries in the Northern Hemisphere by radio. This is the belief of Kenneth B. Warner, secretary of the American Relay League, the amateur organization which furnished a radio operator for the polar party which left Wiscasset, Me., last week on their voyage to Ellesmere Land.

So convinced is he that messages from WNP, the radio station on MacMillan's schooner, will reach amateurs in other countries beside the United States that he has notified amateurs in England and France to be on the alert. He estimates that either one of these two countries is about equally distant to Ellesmere Land as the average point in the United States.

He has pointed out that the distance between Ellesmere Land and England is far less than the distance between the Middle West and England, which was covered many times during the amateur Trans-Atlantic tests of last year. At this time the amateur station operated by Irving Vermilya, New Bedford, Mass., succeeded in sending fourteen complete messages to an amateur in England.

The failure to establish direct two-way communication between American amateurs and those in England and France may now resolve itself into an intercontinent relay by way of the North Pole. For example, messages from amateurs in this country may be sent to Donald H. Mix, operator on MacMillan's ship, and relayed by him to amateurs in any of the Northern European countries. Similarly amateurs across the Atlantic can relay through the station in the far North.

Already Mr. Vermilya and other American amateurs, whose records have been the envy of all operators, are getting their sets in readiness to communicate with members of the exploring party and are looking forward to what may be the most spectacular radio feat which has yet been attempted.

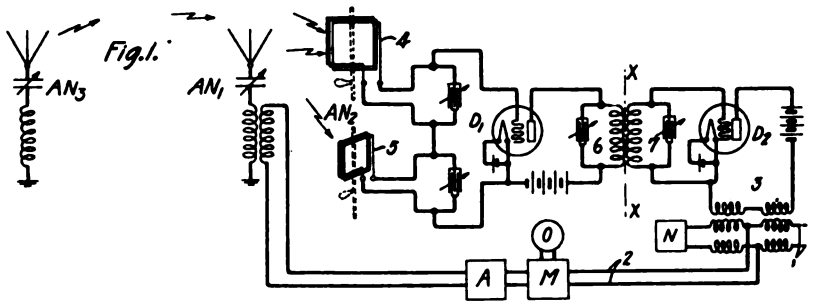
Latest Radio Patents

Radio Receiving Circuits

No. 1,457,447: Patented June 5, 1923. Patentee: John Mills, Wyoming, N. J.

THIS invention relates to radio-receiving circuits, and particularly to that type employing the principle of successive detection.

The term "successive detection" as here used is given its usual signification as involving the function of stepping down the frequency of the received radio-frequency waves to an intermediate high frequency by one detecting operation and employing a subsequent detecting operation to obtain the low frequency modulating component. According to the present invention the wave to be received and an auxiliary radio wave are received and impressed together upon the input circuit of the first detector, by which the first frequency reduction is accomplished. The auxiliary wave is given such a frequency that, by combination with the normally received wave, there will result in the output circuit of said detector an intermediate frequency wave having a desired periodicity. The auxiliary wave source may have its sole function as above indicated or it may combine this function with that of a source for transmitting waves to the distant station, the circuits associated with said source and the receiving circuits constituting the terminal circuits of a complete two-way channel. A system characterized generally by the production of intermediate frequency waves at the receiver will be designated an "intermediate frequency system," the specific type in which the auxiliary wave source has a double function, as described, being correspondingly designated a "modified intermediate frequency system." A receiving circuit having means for stepping down the frequency of its normally received wave by combination with an auxiliary frequency wave, whether said auxiliary wave has the additional function mentioned or not, will be designated an "intermediate frequency receiving circuit." The auxiliary frequency source will be designated as a "local" source, and its circuit as the "local transmitting circuit."



John Mills' system of alleviating interference by means of intertuned receivers.

The principal object of the present invention is to provide a means whereby, in an intermediate frequency receiving circuit, a regular amount of auxiliary radio carrier wave may be impressed on the input circuit of the first detector without detriment to reception from the distant station.

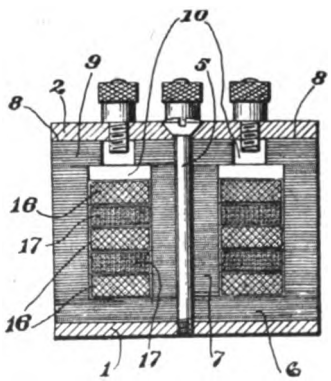
Audio-Frequency Coupling Transformer

No. 1,457,619: Patented June 5, 1923. Patentee: Samuel Cohen, Brooklyn, N. Y.

THE main object of this invention is to provide an efficient audio-frequency transformer of superior utility and applicability to transformers similarly used in radio electrical arts.

The essential points in obtaining an efficient audio-frequency coupling transformer are, briefly, the following: The ratio of the reactance to the resistance should be a maximum; the ratio of number of turns in the primary winding to the number of turns in the secondary winding should be a maximum; the degree of coupling between the primary and secondary windings should be a maximum; the leakage reactance of the core and windings should be a minimum; no external magnetic field should exist when the transformer is in operation in order to prevent stray fields from producing coupling between transformers and neighboring electrical apparatus and thereby preventing the generation of electromotive forces of audio-frequency; the coupling transformer in toto should have minimum physical dimensions.

It is the aim of this invention to accomplish the above-mentioned design and arrangement in a practical manner and yet approaching theoretical perfection as near as possible.



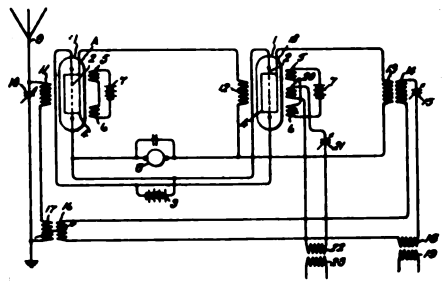
New method of transformer construction, using several sectional windings for primary and secondary, allowing maximum coupling.

To many anxious inquirers: RADIO WORLD has no free list. One copy is sent as a voucher to each advertiser or advertising agent represented in current issues. All other copies are paid for on subscription or through the news trade.

Amplifier

No. 1,457,814: Patented June 5, 1923. Patentee: Howard L. Becker, Schenectady, N. Y.

THE present invention relates to amplifiers of the electron discharge type, and more particularly to magnetically controlled amplifiers. One of the objects of the invention is to provide a simple and efficient circuit connection of magnetically controlled amplifiers whereby a high degree of amplification may be obtained. A more specific object of the invention is to provide an amplifying system in which successive amplification of small currents may be produced in a single device.



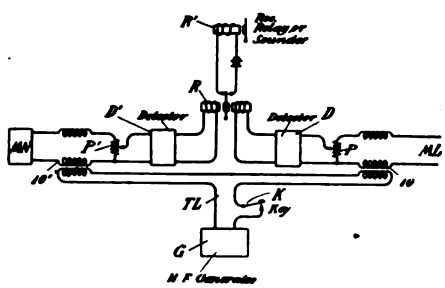
Amplifier providing successive amplification of small currents in a single tube.

Balancing Circuits

No. 1,457,336: Patented June 5, 1923. Patentee: Herman A. Affel, Brooklyn, N. Y.

THIS invention relates to signaling circuits, and more particularly to arrangements for translating low frequency signals into higher frequency carrier currents and vice versa.

In multiplex transmission systems employing carrier currents it is customary to separate the east and west channels of a carrier transmission circuit in a manner similar to that employed in the case of the so-called 22 type telephone repeaters. A circuit of this type involves balancing the carrier frequencies by means of an artificial line for simulating the main transmission line at the carrier frequencies. A low frequency balance is usually also provided in connection with the terminal signaling circuit to maintain the oppositely directed channels conjugate at low frequency. The translation of the ordinary signaling frequencies into carrier frequencies and vice versa is carried out independently of the balancing circuit. In accordance with the present invention the frequency translation is made an integral part of the balancing circuit by locating the translating device, which may be either a modulator or demodulator, in the circuit on either side of the point of neutralization between the real and artificial line. Consequently the energy of an outgoing transmission, for instance, which it is desired to balance with reference to the receiving channel, undergoes a change in frequency before the balance is effected. An arrangement of this character renders it possible to balance the circuit without maintaining a high degree of balance in the artificial line or network for both high frequency phase and magnitude.



Means of balancing both sides of a carrier wave in transmission.

Answers to Readers of Radio World

IN relation to loading sets for higher wave lengths, how is it possible to load the Flewelling super circuit for higher waves? Can they be loaded for waves up to 25,000 meters? Is it possible to load a 4-tube reflex circuit up to that wave?—H. R. Loring, General Delivery, Bellaire, Ohio.

You cannot efficiently load a circuit of the Flewelling type up to that high wave length. It is not necessary for you to use a circuit of this type to reach the high wave lengths. To do it right you should use the three-circuit, honeycomb circuit, whereby you can easily reach the high waves, and get POZ and FL, and all the other high-power stations on one tube. These stations are of such extremely high power that it is not necessary to even use a tube; but, by means of a tickler, or slipping contact wheel, in the detector circuit, they can be reached by a crystal detector, using the double-circuit crystal hook-up with the larger honeycombs.

If you desire to load a reflex circuit it will be necessary for you to get special radio-frequency transformers that encompass this band of wave lengths. They are not generally manufactured, so it will be necessary for you to have them made to order; but no advantage would be gained by their use, as then only the extremely long wave lengths of from about 15,000 to 25,000 meters could be received.

* * *

I have made up the Cockaday circuit recently described in RADIO WORLD *by R. P. May, and am in trouble in the following manner: When I leave the phone condenser off my set squeals and the signals are muffled, and when the condenser is in the signals are clear but weak. The tuning is sharp, but I can only get each station at a definite setting of the dials. A definite setting has to be used for each separate station. The set does not seem to be regenerative at all, and I wonder if reversing the B coil might be the cause. I have been using WD-11 tubes, with 22½ volts on the plate.—B. R. White, 641 Washington Avenue, New York City.*

One of the features of this set is the regeneration without any of the effects, such as re-radiation of signals. The fact that you are using the WD-11 tubes would account for the weak signals, as this set does not operate successfully on the dry-cell tubes. Better results can be had if it is worked with the U. V. tubes. Reverse your B coil, as suggested and shown in the diagram. If this coil does not run in the same direction as the other coils the coils oppose each other, and that will cause the trouble you mention.

* * *

I have recently built a Stockleburg Pup Set and have obtained wonderful results. I have trouble, however, with body capacity, and have to operate it very carefully, otherwise the set howls like a "pup." Would placing the honeycomb coil in the position shown be of any help in removing this? Should the copper foil ground be grounded? Where? Would better results be obtained if the variable condenser was removed from the front of the panel by placing wooden blocks between the condenser and the panel? Should the leads be insulated by spaghetti or rubber tubing? Would lining the cabinet with copper foil be of any benefit in removing the body capacity effect?—J. L. McNabb, 826 Ann Street, Columbus, Ohio.

Placing the coil in the position shown in the sketch you send would probably help it a little. You should ground the panel shielding to the ground post of the set. It would probably help if the condenser is mounted as suggested, but in that case a non-metallic rod would have to be used to manipulate it, as otherwise the mounting would not have any effect as the use of a metal rod would carry the body capacity to the set through the metal just the same as if you did not mount it in the manner described. It is not absolutely necessary to insulate the leads except where they cross at extremely close quarters, and in that case they should be insulated. Lining the cabinet in the manner suggested would obviously help in the elimination of the disturbing capacity effect. In this case the entire cabinet should be grounded, but take extreme care that no part of it touches the shielding.

* * *

In RADIO WORLD *for April 21 you describe a double-control switch in connection with a circuit by Arthur Gordon. I note that the negative B battery is connected to the negative A lead, and have had my connection on the positive A lead. Which is correct?—E. V. R. Harris, Woodstock, N. B., Canada.*

The circuit will work either way. Better results are sometimes had with the connection you mention, but it is a matter of experiment, and can easily be determined which works best by simply shifting the leads of your A battery.

* * *

In connection with the combined transmitting and receiving circuit published in RADIO WORLD *for May 19, what is the capacity of the grid leak? Would better results be had by the use of a power tube in this circuit?—William T. Deasy, 74 Quericus Avenue, Willimantic, Conn.*

The grid leak should be 1-5 megohms resistance. A variable one will suit the purpose. You can use a power tube with this circuit if you wish. This will allow you to use more power in your plate circuit and consequently reach further.

* * *

I constructed the Cockaday receiver according to your description and circuit diagram in RADIO WORLD *for May 12, but find that I cannot get anything but a dull hum or click. This is more pronounced when I turn the tube off. Could this be caused by using a faulty socket?—Herman C. Menes, 4 Otisfield Street, Roxbury, Mass.*

The fact that you get a dull hum or buzz in your circuit is an indication that you have a break somewhere in the circuit. This could be caused by a faulty socket, the prongs making poor contact with the nipples of the tube. Go over your circuit very carefully, testing out each connection, to see if there is not a faulty contact. Examine all your movable contacts, such as tap leads, and you will probably find your trouble.

* * *

Is the enclosed circuit a good one? Will a tube detector be more efficient than a crystal detector? Is it possible to use two variometers, coupler, etc., with this circuit instead of the loop and condensers? Where can I purchase resistances of 500 to 2,000 ohms?—E. L. Mason, Essex, N. Y.

The circuit you enclose is the reflex circuit used in the De Forest D7 set. It is possible to use a tube detector with this circuit, but better and clearer reception will be had if the crystal is used. The tube will add but little to the operating sensitivity of the set, and the signals will most probably be much distorted when it is used. Stick to the diagram. You cannot combine this set with a variometer and coupler, though you can use a coupler as a tuner with an antenna and ground, but the variometers are useless in this circuit. Write to any of the radio supply houses advertising in RADIO WORLD.

* * *

Kindly publish a correct circuit diagram of the De Forest D7 loop set. In RADIO WORLD *for June 2 you published a ship receiver using the Grimes inverse duplex reflex receiver. Can I use U. V.-200 tubes with this receiver? Can I use dry-cell tubes? Is it advisable to use a three-stage amplifier in connection with the De Forest? They are to use dry cells.—Walter H. Spieler, 19 Mystic Avenue, Somerville, Mass.*

For the De Forest reflex we refer you to the Answers to Readers column in our issue for June 23, where you will find the circuit requested. It is not desirable to use U. V.-200 tubes with this circuit as the tubes have to perform the work of amplifiers. The last or detector tube can be a soft tube, but otherwise use the amplifying tubes. It is possible to use the dry-cell tubes with this circuit, but results will not be as good when these tubes are used as when the regular large plate surface tube is employed.

There should be no need for adding more amplification to a set of the De Forest type. You will obtain three steps of radio and two of audio-frequency amplification with such an outfit, which is all that is necessary. More than this will distort the signals, and the added expense is not warranted. More than two steps of audio-frequency or three steps at the most tend to rob the signals of their clarity, and you will obtain nothing but a lot of noises.

* * *

Kindly advise me where I can get a diagram of a three-circuit set using two variometers and a coupler in connection with a panel diagram and two stages of audio-frequency. Is it necessary to shield the panel? Does it make any difference if the two variometers are of different makes?—William J. Watt, 104 Commercial Street, Rochester, N. Y.

We refer you to RADIO WORLD for June 30, where you will find the necessary data for the construction and operation of a regenerative set for which you ask. For proper operation the set should be shielded, preferably with copper foil or screening. It should not make much difference if the two variometers do not vary too greatly in size. The smaller one, or the one with the least number of turns, should be put in the grid circuit.

* * *

I constructed the Stockleburg Pup Set described in RADIO WORLD *for May 5, but cannot seem to get any regeneration. Kindly explain why I can only get results when tapping the coil at the eleventh turn.—E. Cutris, P. O. Box 718, City Hall Station, New York City.*

You should tap your coil at the inside of the honeycomb. Start at the inside and count the turns, not the layers, as otherwise you will not get the correct amount of wire in your plate circuit. This accounts for the fact that you have to tap it at the eleventh turn. It will give you plenty of regeneration when tapped right.

* * *

Please send me the correct hook-up for the set described by Orthcrus Gordon that appeared in the January 20 issue of RADIO WORLD.*—C. W. Gildner, Pittsburgh, Pa.*

The hook-up as it appeared is correct.

Using the MAGNAVOX

IT is the Magnavox owner who gets the utmost service from Radio.

While the Radio enthusiast constantly strives to better his receiving equipment, Magnavox Reproducers and Power Amplifiers are units which no other apparatus can replace.

The only correct principles of sound reproduction and amplification are embodied in Magnavox construction.

Magnavox Reproducers and Power Amplifiers can be used with any receiving set of good quality. Without Magnavox, no receiving set is complete.

Magnavox R2 Reproducer and 2 stage Power Amplifier (as illustrated) **$115.00**

R2 Magnavox Reproducer with 18-inch curvex horn: the utmost in amplifying power; requires only .6 of an ampere for the field **$60.00**

R3 Magnavox Reproducer with 14-inch curvex horn: ideal for homes, offices, etc. . . . **$35.00**

Model C Magnavox Power Amplifier insures getting the largest possible power input for your Magnavox Reproducer.

AC-2-C, 2-stage, $55.00
AC-3-C, 3-stage, $75.00

Helping to Keep the "Stay-at-Homes" happy

RADIO has banished that dull, lonely evening idea once and for all—the "stay-at-home" nowadays can choose his own brand of entertainment from a number of programs practically every hour.

But a Radio set is only as good as its *reproducer* — make sure you have the Magnavox (electro-dynamic) Reproducer Supreme.

Magnavox products can be had of good dealers everywhere. Send for copy of unusual booklet.

The Magnavox Co., Oakland, California
New York: 370 Seventh Avenue

Radio Literature Wanted

Manufacturers of and dealers in radio apparatus and accessories are notified that literature and catalogues describing their products have been requested, through the Service Editor of RADIO WORLD, by the following:

Burke Hennessy, 30 Fifth Avenue, New Rochelle, N. Y.
H. R. Whaley, 220 North Tod Avenue, Warren, O.
Tom Kolonsh, 607 North Eighteenth Street, Omaha, Neb.
Charles Glatz, 850 Stebbins Avenue, Bronx, N. Y. (Makes sets to order.)
H. Adams, 27 Converse Street, Wakefield, Mass.
A. S. Diehl, Box 154, Lake Arthur, La.
Elden Peterson, P. O. Box 95, Winthrop Harbor, Ill. (Consumer and retailer.)
Frederick James Hellmer, E.E., 6211 Toledo Avenue, Detroit, Mich. (Builds and designs sets.)
J. L. Bostian, 8 Hammond Place, Elmhurst, L. I., N. Y. (In market for home set costing $150 to $200.)
H. B. Helein, 526 Church Street, New Britain, Conn. (Makes radio sets.)
H. D. Burrall, care U. S. Forest Service, Magdalena, New Mexico.
Ervin F. Schubel, R. 2, Lake Beulah, Wis. (Possibly may become a retailer.)
Bernard S. Shay, 3016 Holmes Avenue, South, Minneapolis, Minn. (Will soon open radio store and shop. Wants first-class parts.)
G. A. Fassnacht, 5616 Second Avenue, South, Minneapolis, Minn.
R. O. Lamb, 18 Trenton Avenue, Swissvale Station, Pittsburgh, Pa. (Neighborhood supply dealer.)
J. J. De Back, 38 Arbutis Street, Rochester, N. Y. (Interested in both receiving and transnitting.)
Marks Bros., 2312 Eighth Avenue, New York City. (Dealers.)
F. Elphick, 706 Hudson Avenue, Secaucus, N. J.
Simplex Radio Supply Co., 1806 Lafayette Avenue, St. Louis, Mo. (Wholesale and retail mail-order house.)
R. J. Russell, 5013 Baltimore Avenue, West Philadelphia, Pa.
L. Seltzer, 272 Saratoga Avenue, Brooklyn, N. Y.
Essex Mfg. Co., 117 Mulberry Street, Newark, N. J. (Jobbers and dealers.)
W. A. Wynne, 120 South Salisbury Street, Raleigh, N. C. (Dealer.)
W. F. Kuhn, 2209 South 39th Street, St. Louis, Mo.
Dr. F. M. Cooper, 14 South Weber Street, Colorado Springs, Colo. (Soon be in market for parts for one or two portables.)
Tillman Products Co., 473 Hudson Avenue, Brooklyn, N. Y. (Manufacturers. In market for molded rheostat bases, sockets and crystal detector bases only.)
John Logan, 1955 Morengo Ave., South Pasadena, Calif.
W. Gilbertson, Hickson, North Dakota.
Dean French Taylor, 43 Black Rock Turnpike, Bridgeport, Conn.
L. A. Wallace, Engineer's Office, Beaufort County Road Commission, Washington, North Carolina.
C. W. Thomas, Huntingdon, Quebec, Canada.
Swain Solon, Shenandoah, Iowa. (Dealer.)
Michael Moss, 2275 Morris Ave., Bronx, N. Y.
J. Lawton Ellis, Jr., electrical engineer, Allendale, South Carolina. (Radio service.)
Wm. Messenger, 238 Eighth Ave., N. E., North St. Paul, Minn.
John L. Heath, Box 395, Derby Line, Vermont. (Builds, repairs and installs sets.)
H. B. Phinny, 310 West First Street, Oil City, Pa.
W. H. Burnham, 727 Tremont Street, Boston, Mass.
George Kotz, 5534 Pemberton Street, West Philadelphia, Pa.

The first of these names were printed in Radio World dated April 21, and have continued in each issue since. Any copy 15c. Any 7 copies for $1.00 Radio World, 1493 Broadway, N. Y.

Investigates Broadcasting in England

M. C. RYPINSKI, vice-president of C. Brandes, Inc., and chairman of the radio section of the Associated Manufacturers of Electrical Supplies, returned from Europe last week on the "Homeric."

Before the British Broadcasting Society he explained American broadcasting methods and will shortly give talks in New York, Pittsburgh and Chicago, over radio, on British broadcasting methods.

Mr. Rypinski says that the opportunity to investigate the British broadcasting situation was most helpful and interesting.

The British public have been quick to take the idea, and as this public numbers fifty million or more their interest in radio broadcasting is bound to be fraught with important developments.

M. C. Rypinski, of New York City, who investigated broadcasting in Great Britain

He was also impressed with the unified control over broadcasting vested in the British Broadcasting Company, which is an association of about 500 radio manufacturers (membership open to any bona fide British manufacturer), acting under the supervision of the Postmaster General. This unified control obviates duplication of expense, minimizes interference and should develop a very high standard of broadcasting program and operation.

Radio Trade Opportunities

PROSPECTIVE purchasers of radio equipment in Riviere du Loup, Quebec, Canada, have filed inquiries with the Department of Commerce, Washington, D. C., as to exporters in the United States. The names and full data are available upon application under Trade Opportunity 6888. Other inquiries on radio parts have also been received from London and may be referred to as No. 6908.

No. 6,862 refers to an agency for radio equipment and apparatus desired in Newcastle, Australia.

New Radio and Electric Firms

Electro Company, New York, has increased its capital stock from $4,000,000 to $4,750,000.

Consolidated Telegraph and Electrical Subway Co., New York City, will issue 37,500 shares preferred stock and 442,500 shares common stock, both of no par value.

Ceasar Electric & Radio Corp., New York City, $50,000; P. Dicesare, W. H. Grote. (Attorney, F. S. Marsell, 154 Nassau St.

Albany Radio Corp., Albany, N. Y., has increased its capital stock from $10,000 to $50,000.

Berling Magneto Co., Buffalo, N. Y., $40,000; W. J. Daetsch, W. E. Barrett. (Attorney, N. C. Kropp, Buffalo).

American Broadcasting Corp., New York City, $5,000; C. Tepper, S. H. Gore. (Attorney, I. M. Sackin, 152 West 42d St.)

The Plateau Valley Light & Power Company, Colbran, Colo.; capital stock, $100,000; Clarence L. Fenn, George Bullock and M. R. Groves.

The Cambridge (Ohio) Light & Power Company; capital stock, $75,000; Frank M. Taylor, Robert S. Ashe and Wilfred Jessup.

R. V. English Electrical Co., Buffalo, N. Y.; $10,000; J. M. Mead, R. V. English, E. W. Hartung. (Attorney, H. P. Miller, Buffalo.)

Ambrose Diehl Electric Co., Uniontown, Pa., has increased its capital stock from $150,000 to $275,000.

Sprague Electrical Supply Co., 39 Spring Street, Waterbury, Conn. (Wholesale.)

Arrow Supply Co., 107 North 7th Street, Philadelphia, Pa. (Wholesale.)

W. M. Rosenthal, 726 Atlantic Avenue, Atlantic City, N. J.

Edward S. Peacock, 215 West Washington Street, South Bend, Ind.

Allison Cash Hardware Co., Allison, Ia.

Meredith Hardware Co., 721 West Grand Avenue, Des Moines, Ia.

E. C. Harkness, 1630 North Capital Street, Washington, D. C.

UNITED STATES DISTRICT COURT, SOUTHERN DISTRICT OF NEW YORK:
No. 34404 In Bankruptcy.
C. HYMAN BATNER, Bankrupt.
TO THE CREDITORS OF THE ABOVE NAMED BANKRUPT:

Pursuant to Southern District Rule 22 you are hereby notified that the Receiver, Attorney for Receiver and Petitioning Creditors, and the Appraisers herein, have filed petitions in writing for allowances for services rendered the estate of the above named bankrupt, as follows:

GABRIEL I. LEWIS, receiver's commissions $30.26
Allowance to ARCHIBALD PALMER, attorney for Receiver..... 60.52
Disbursements 1.00
BERNARD J. McCORRY, appraiser.... 10.00
ARTHUR C. SMITH, appraiser..... 10.00
CLIFFORD G. LUDVIGH, appraiser.... 10.00

YOU ARE HEREBY NOTIFIED that the said applications for services rendered said estate, will be brought on for hearing before me as Referee, at my office, No. 2 Rector Street, City of New York, on July 12th, 1923, at 1 P. M., at which meeting the said matter will be heard and such recommendation made as may be just and proper.

SEAMAN MILLER.
Referee in Bankruptcy.
Dated, June 25th, 1923.

Dry Cell Tubes Increase Portability of Radio Sets

By Gerald McSweeney

A YEAR ago the idea of taking a radio receiving set on one's vacation was usually regarded as very impractical and somewhat inconvenient. The ordinary crystal receiving set was not satisfactory and the tube set was bulky and inconvenient. Now, however, the developments of the past year not only make it possible but advisable to carry a radio set to camp or summer resort.

As a result of the application of the single dry cell battery such as the WD-11 it is now possible to use a vacuum tube set in places remote from storage battery charging facilities such as the isolated farm, the seashore and the summer camp.

There is no limit to the lengths we may now go. The disciple of Izaak Walton can take his outfit with him to some shady nook, and if the fish are not biting well, he can while away the hours listening to the soothing strains of music a la radio from a broadcaster miles distant, or he can take in a lecture on how to fish, or hear a discussion on the fall styles in evening wear, not to mention the baseball scores. The portable transmitter, installed at the camp, will insure that he does not miss the dinner bell.

The canoe, the motor boat, the automobile, and even the motorcycle of the ambitious camper will this summer be equipped with a radio receiver, and no matter where you go, you will be within easy range of one or more broadcasters.

No argument is necessary to convince the reader, well informed on radio matters that the messy 6 volt storage battery is poorly adapted to portable radio sets on account of weight, bulk and the necessity of having to provide frequent charging means. The actual weight reduction is approximately 40 pounds—lesser weights are often the determining factor in the selection of camp equipment.

Most of the interference handicaps usual to cities and congested centers due to steel structures and power lines are dissipated in the great open spaces and with the exception of intense summer static conditions splendid results may be expected due to the high sensitivity of the vacuum tube receiver. Through processes recently developed the Westinghouse WD-11 and WD-12 dry cell tubes has been perfected to the point where if not mistreated its life is in the neighborhood of 1,000 hours.

The characteristics of WD-11 and WD-12 are identical the only difference being WD-11 is equipped with special base for which it requires an adapter for use in standard sockets. WD-11 is equipped with standard base.

In constructing these tubes the tungsten filament is replaced by a platinum filament coated with salts that will allow greater electron omission with less battery capacity—this development has made possible a tube having all the desirable qualities of an untreated tungsten filament tube which can be operated from the power supplied from a common dry battery. The WD tubes are exhausted to an extremely high vacuum and they do not depend on enclosed gas for their detecting properties. They are thus not critical in any adjustment either to filament, current, plate voltage or to the constants of the circuit in which they are used.

Another advantage is that the dry cells necessary to operate the tube can be purchased for about forty cents and they are rarely difficult to procure even in the smallest of villages or country stores. Therefore, if your power runs out it is very easy, cheap and convenient to replenish.

The farmer now can enjoy with his suburban and city brother the daily weather, time and market reports as well as the many entertaining and instructing features provided by more than 600 broadcasting stations.

The research laboratories devoted to the radio field have concentrated on broadcasting receiving apparatus in an endeavor to broaden the field of application. It remained for Westinghouse to improve the mechanical features of the dry battery tube set and to make it a commercial success.

The outstanding advantage of the tube set is that it uses the antenna current to control relatively large amounts of energy supplied by a local battery while the crystal set is directly dependent on the received energy. The advantage of a set equipped with WD-11 or WD-12 tubes is its adaptability to a convenient and compact source of energy.

Dubilier's Annual Report

THE Dubilier Condenser and Radio Corporation, New York City, for the year ended April 30, 1923, reports a balance of $63,588, after expenses, taxes, preferred dividends and sinking fund reserve, which is equal to 48 cents a share earned on the 131,000 shares of common stock outstanding. The income statement for the year shows sales of $516,058; operating expenses, taxes, etc., $425,938, and net operating profit, $93,588. The corporation's total surplus stands at $73,588.

The Accuratune Micrometer Control Dial

A NEW micrometer control dial manufactured by the Mydar Radio Company, Newark, N. J., embodies several novel and helpful features that will prove of advantage to the owner of a set who desires fine tuning. The dial proper is of aluminum-finished brass with an extra large knob for coarse tuning. On top of this larger knob there is a smaller one. By an ingenious arrangement of gears located inside the larger knob it is possible to get extremely fine tuning, as one complete turn of the micrometer control only moves the dial a hair line, and it is therefore possible to get an adjustment that is impossible by the usual methods. This will prove to be a great help in a set that needs fine controls, and, inasmuch as it is handsomely engraved and constructed, should be a welcome addition to any set.

Will a *Reliable* Wholesaler Please Reply

Editor, RADIO WORLD: We carry a general side line of radio supplies, we are buying and selling for cash, but so far have not found a reliable wholesaler that does business in a regular, dependable manner. They either ask prices that are too high or the product is poor. Can you suggest a way to overcome this condition?

Where can we obtain a list of reliable *wholesalers only?* We would be thankful to you for the above solutions.

JOS. C. HEINTZ.
12 Sixth Street, New Dorp, N. Y.

Coming Events

AMERICAN RADIO EXPOSITION, Grand Central Palace, New York City, October 6 to 13, 1923. J. C. Johnson, general manager.

ANNUAL HOME AND CITY BEAUTIFUL EXPOSITION, featuring radio exhibits, Atlantic City, N. J., June 16 to September 8, 1923.

Broadcasting Post Cards

THE Pacific Screw Company, 645 N. E. 53rd Street, Portland, Oregon, dealers in radio supplies, have prepared two postal cards for use in acknowledging receipt of broadcasts and for replies to enable receiving stations to know what their outfits are picking up. The forms adopted seem to fulfill the purposes intended. The cards are supplied by the dozen or in quantities.

Radio Improvements in Mexico

THE Mexican Government intends to change the apparatus used in its wireless stations from spark to continuous wave, according to information reaching the Department of Commerce. With the present spark sets, it is reported that the Mexican stations can communicate only with two European stations; one at Nauen, Germany, and the other Lafayette, at Bordeaux, France. Equipment for four modern transmission stations of continuous-wave type have been ordered from Germany at a cost of $200,000. They will be installed at Mexico City, Merida, Vera Cruz and Tampico. The old spark stations will be transferred to the Islas Marias; LaPaz, Lower California; Guadalajara, Jalisco, and Acapulco, Guerro.

Radio Committee of Supply Jobbers' Association Reports

AT a general meeting of the Electrical Supply Jobbers' Association, held at Hot Springs last month, the following recommendations were presented by the Radio Committee and unanimously adopted by the association:

That manufacturers of radio material supply their distributors with standard size 8½ by 10 inch price and data sheets.

That defective tubes and radio material returned to manufacturers, where such returns are permitted, be credited rather than replaced, in the interest of economy, by the elimination of handling small shipments, as in most cases the distributor has already made replacement or adjustment with the dealer.

That all portions of inside of instruments depending on the strength of panel for support be reinforced by extra individual support of such unit so mounted to prevent breakage by rough handling.

That manufacturers pack and ship receiving sets in individual cartons or crates of sufficient strength to permit reshipment in original package.

That all manufacturers of receiving sets of a value of $25 or over supply these sets with a serial number to facilitate the tracing of lost or stolen sets, and that the serial number and catalog number appear on the outside of the container, where it will appear to the best advantage in stocking on distributors' and dealers' shelves, and further recommends that manufacturer, distributor and dealer use serial numbers on their invoices.

That the present practice of allotting radio material on which the demand exceeds the supply be changed to conform to the practice of manufacturers of other lines handled by distributors, thereby rewarding distributors who create business and placing supplies where the demand is most urgent.

KELLY WAVE SUSTAINING COIL

Eliminates Aerials, Loops and Danger from Lightning

Fit Inside Set

The Kelly Wave Sustaining Coil will work perfectly in any tube set. The coil being sealed under a vacuum, it eliminates STATIC and all interferences.

Price $4 Each

Makes It Portable

Simple to connect. One lead to terminal marked aerial, the other to A or B battery—That's all.

Dealers, write for special terms.

Manufactured by

JOS. GELB COMPANY, 250-258 West 54th Street, New York

"B" BATTERIES

Depleted "B" Batteries are usually the cause of your trouble in receiving. Eliminate it. Buy your "B" Batteries direct from Manufacturer. No old stock batteries, but fresh tested batteries, with a 100 per cent. efficiency, at the following low prices, which are 50% less than list price.

	Large	Medium	Small
22½ Volt plain	$1.25	$1.00	$0.70
22½ Volt variable	$1.38	$1.13	$0.75
45 Volt plain	$2.50	$1.75	—
45 Volt variable	$2.75	$2.00	—

Any other type of battery made to order. Send Money Order or Order for C.O.D.

ROSENDAL & CO., 2 Stone Street, New York

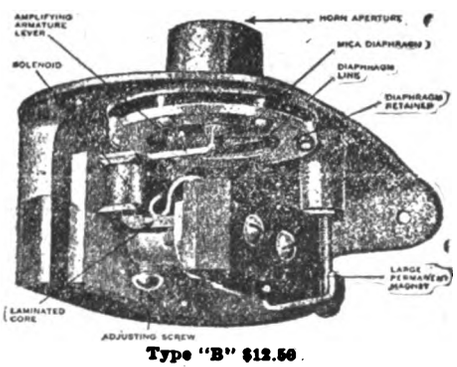
The Trinity Loud Speaker

TYPE "A1"

$25.00

21-in. Fiber Horn

The only device of its kind in the Radio field



Type "B" $12.50

Study the illustration carefully and you will understand why it produces full, clear, natural tones with perfect reproduction of all vocal and instrumental music. May be used with phonograph. No storage battery required.

The Trinity Loud Speaker is an instrument that combines the best qualities of a phonograph reproducer in combination with electro magnetic principles best fitted for radio amplification. Absolutely perfect reproduction of all music and speech without distortion. The volume may be regulated from that required for a room in your home to a tremendous output that can be heard hundreds of feet out of doors by simply increasing "B" battery voltage. No storage batteries required. The instrument is of a heavy duty type and is guaranteed fully by the manufacturers.

Ask your dealer for demonstration—if he cannot we can.

Milwaukee Radio Amateur's Club

MUCH interest in the Zenith receptor has been aroused among members of the Milwaukee Radio Amateurs' Club, Inc. Several have built models according to the specifications given before a recent club meeting by R. H. G. Mathews, 9ZN, engineer of the Chicago Radio Laboratory, and have reported favorably on the receiver's merits. Among these were E. T. Howell, Sc.M., vice-president, and the club's recently appointed assistant treasurer; F. W. Catel, 9DTK, some time an operator for the now defunct United Wireless Telegraph Company.

A good share of one of the season's last meetings was taken up with a discussion of the super-heterdyne receptor, with E. T. Howell, 9CVI, and H. F. Wareing, pre-war 9AEX and president, leading.

At the final meeting for the season of 1922-23 Business Manager L. S. Hillegas-Baird read Dr. D. B. McMillan's parting message to A. R. R. L. members. This statement was prepared by Dr. McMillan shortly before he left for the Arctic regions, taking an A. R. R. L. member and radio operator with him.

Regular weekly meetings on Thursday evenings will be resumed by the society about the middle of September. The club's directors and officers will hold several midsummer meetings, at which plans will be formed for the fall membership campaign. A society consisting of 100 per cent of the local radio amateurs and members of the American Radio Relay League, Inc., is the goal to be set in the membership drive. The club's office, to which all general correspondence should be addressed, is 601 Enterprise Building, Milwaukee, Wis.

Broadcasting in 1874

RADIO broadcasting is a development of the past three years but the broadcasting of music goes back a great many years. George S. Pierson, a consulting engineer of Kalamazoo, Mich., writing to WGY, the Schenectady, N. Y., station of the General Electric Company, acknowledging his enjoyment of many programs, tells of a broadcasting stunt enacted by the students of Union College on a frosty March night in 1874.

The generator, he explains, was what is commonly known as a horse fiddle, a great wooden box on the main floor of a circular building, now the library, then in course of construction and roofless. The top boards of the box were well resined and a plank 38 feet long used as the fiddle bow was also resined. With six men standing on the plank, the bow was drawn back and forth across the edges of the box. No one in Schenectady slept that night and the terrifying notes of the mammoth fiddle were heard five miles away.

Mr. Pierson also describes, as a parallel to the progress of radio, a demonstration of the telephone which was made in 1874 in a Schenectady church. An admission fee was charged. A telephone line was strung from pulpit to gallery. The audience was invited to listen into the wonderful invention, but, according to Mr. Pierson, no two people were able to agree on what was said over the wire.

Station WDT Reopens in New Quarters

Station WDT is now located in new quarters at 510 West Twenty-third Street, New York City, under the direction of Vaughn De Leath. This broadcasting station is operated by the Ship Owners' Radio Service, Inc., and the Premier Grand Piano Corporation. It is planned to produce WDT programs of unusual merit

IMPORTANT NOTICE

While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

Rubber in Tremendous Demand

TO make the thousands of various rubber articles, the majority of which are essential to public convenience, more than 250,000 tons of crude rubber are required to supply the world market. Since rubber must be taken from certain tropical trees in the form of latex, or sap, which is more than 60 per cent water, it takes 224,000,000 gallons of the milky fluid to produce the tonnage required to supply the rubber manufacturing industry.

The rubber latex or milk is not an emulsion, as is commonly supposed, but a fluid in which are suspended microscopic particles of solid rubber matter. These particles are so numerous and their powers of adhesion are so great that one gallon of the white rubber-tree sap contains enough of the rubber globules to form a minute thread 372 miles long.

On the rubber plantation the tree milk or latex is treated with a dilute acid solution as soon as it is brought in by the tappers. The acid serves to dissolve the properties which hold the rubber particles suspended in the fluid. This brings the rubber to the surface, where it can be skimmed off just as cream is skimmed off milk.

The value of the plantation rubber to the industry has been tremendous. Scientific care of plantations and extensive study of methods for handling the latex have produced a dependable rubber which the manufacturer can study and compound with the assurance of more uniform service results in the product he makes from it.

"Leviathan" Establishes Marine Radio Records

In addition to making world speed records during her recent trial trip, the "Leviathan" established three marine radio records for volume of traffic, range of transmission and reception and for operation of duplex telegraph and telephone system. Under the personal supervision of David Sarnoff, vice-president of the Radio Corporation of America, and G. Harold Porter, general superintendent, the radio operators received and transmitted an estimated total of 750,000 words, or 15,000 a day, the greater volume press dispatches. Mr. Sarnoff, himself an expert operator, frequently sat at the key in facilitating the quick transmission of press dispatches.

"On this trip," Mr. Sarnoff said to a New York *Times* correspondent, "there were more messages sent and received daily on the ship than are handled every twenty-four hours between the United States and any one European country. On Saturday, the last day at sea, everything known in radio science was employed to handle the tremendous volume of business, and the transmission was expedited by the use of the duplex simultaneous sending and receiving apparatus so that four operators were working at the same time.

"Due to the position of the ship in tropical waters and the heat wave along the coast, the static was abnormal, in fact during all my experience as an operator prior to becoming an executive I never have listened to static of such force and intensity. As a result, for the first time in the history of marine radio, was it necessary to use the Cape Cod station and divert it from European communications to the 'Leviathan.' The power and wave length of reception was then increased from 2 kilowatts and 1,600 meters to 200 kilowatts and 16,000 meters. The effect of nature-static was thus overcome by the inventive genius of man."

Mr. Sarnoff said that in diverting the European service of the Cape Cod station to another station, the Radio Corporation had placed at the command of the "Leviathan" radio facilities on land costing approximately $2,000,000.

From the first night out of Boston the radio office was swamped with personal, official and press messages. E. N. Pickerill, chief radio officer, and John R. Irwin, Anthony Tamburino and R. J. Green, operators, worked in four-hour shifts at the keys. In the tropical waters, where the static interfered the most and messages were heard indistinctly on land, Mr. Sarnoff directed three stations to listen in. With more than a hundred correspondents on board, the passengers, among them some of the leading business and financial men of the country, yielded to the press on the question of order of despatch.

"We did not have a single kick from the passengers who were informed that their messages would be delayed in order for the correspondents to get their messages to land," Mr. Sarnoff said. "They felt, as I did, that the newspaper men should be given precedence because they were talking to the American public, which naturally was interested in the performance of the ship."

RECHARGE YOUR OWN BATTERIES

WHY pay out good money constantly for recharging batteries when the Ohio Motor Generator will do it quickly at a slight expense. This inexpensive home charging outfit keeps your Radio in service all the time and pays for itself—by charging your neighbors' batteries. It is noiseless, gives no trouble, and will even recharge totally exhausted batteries quickly.
The set is made up of the celebrated Ohio A C motor and D C generator wound for 6-10 volts. The motor and generator have ball bearings and are of the highest grade construction. It has none of the troubles common to cheap charging sets and will last a lifetime. It will charge quickly any three cell automobile or Radio "A" battery. Furnished complete on a substantial base with ammeter and field rheostat to adjust the charging rate from one to twenty amperes. The motor is for 60 cycle, 110 volt service and is complete with ten foot cord and attachment plug ready for instant connection and operation. Full instructions provided.
Motor and generator can be specially wound to charge six cell batteries or other unusual conditions.
Price $38.50 f. o. b. Cleveland. Ship by Express C. O. D., weight sixty pounds. Send your order today and stop paying good money for recharging. Your money back quick if not satisfactory.
NOTE:—If your service is other than 60 cycle, 110 volt, ask for special price.

Explanation of Radio Time Signals

FROM many inquiries received at Station WOC, Davenport, Iowa, it is evident that the average listener does not understand how to make use of the time signal as transmitted at eleven o'clock each day from the Davenport station. The following explanation has been prepared by the director of WOC:

The series of dots which you hear at that time represent the Government time signal received direct from the Naval Observatory at Washington, D. C., by Western Union, and are broadcast for the purpose of giving all listeners the correct time each day.

By observing the following instructions you will be able to make use of this service:

The time signal is transmitted in a series of dots, each dot representing a second. Beginning, usually, at three minutes before eleven o'clock (Central Standard Time), 29 dots are transmitted, representing the first 29 seconds of that particular minute, and the 30th second is omitted; 25 dots are then transmitted, which represent the first 25 seconds of the last half of that particular minute, and the last 5 seconds of the half minute are omitted. The next minute is transmitted in exactly the same way—that is, 29 and skip 1, 25 and skip 5. On the last minute of the hour, the first half minute is sent the same, that is, 29 and skip 1, and the last half minute is sent out 20 dots and the last 10 are omitted, although in some instances you may hear 21 or 22 dots with 8 or 9 omitted, as the case may be. At the end of this 8 or 9-second interval you will hear a long dash, which represents the exact time, eleven o'clock (Central Standard Time). By watching the difference above noted, you can tell when you are listening to the last minute of the hour rather than any of the others.

The code which follows the final dash is simply a station call.

DYNAMO BUILDING FOR AMATEURS—Or How to Construct a Fifty Watt Dynamo.—By Arthur J. Weed. A practical treatise showing in detail the construction of a small dynamo or motor, the entire machine work of which can be done on a small foot lathe. Dimensioned working drawings are given for each piece of machine work, and each operation is clearly described. This machine, when used as a dynamo, has an output of fifty watts; when used as a motor it will drive a small drill press or lathe. It can be used to drive a sewing machine on any and all ordinary work. The book is illustrated with more than sixty original engravings, showing the actual construction of the different parts. Price, $1.00. THE COLUMBIA PRINT, 1493 Broadway, New York City.

SUPER-SIMPLICITY CIRCUIT—1,000 to 1,500 miles on one tube, one control, 150 to 25,000 meters. Some Good DX Records

Some Crystal Record—Look Out, You One-Tube Fans

From Guy Simmons, Jr., 515 Clifton Street, Conway, Ark., Radio 5WW.

I HAVE been interested in the DX NITE OWL section for some time, especially in those who use a crystal. I am sending you a list of stations which I have heard in about two months' time.

Station	Distance Miles	Station	Distance Miles
KSD	285	WFAA	300
KLZ	750	WLAJ	370
KFAF	750	WAAP	325
KDKA	800	WPE	310
KLW	550	WHAS	450
WOC	475	WLAG	700
WOS	260	WCAL	670
WHB	310	WMAJ	310
WSB	470	WOAW	475
WGM	470	WBAY	1,070
WBAF	330	WEAF	1,070
WDAF	310	WLW	525
WDAJ	470	WMC	150
WWJ	725	WOAI	550
WCX	725	WAAW	475
WSY	350	WDAP	550
WGY	1,130		
WJZ	1,050	Total	18,880
WWAC	370		

A total of 35 stations.

I attribute all my success to a good aerial and ground and to GOOD connections. Let's hear some more crystal records. Will be glad to correspond with anyone interested in crystal work.

His Second Appearance—A Full-Fledged Owl

From Willis Nye, 310 E. Sonoma Ave., Stockton, Cal.

I'VE appeared in your column once before, and thank you for your recognition and privilege to join the DX Nite Owl fraternity. Here is some fairly good dope. Will try to do better next time.

Local DX—KGO, Los Angeles, Cal.; KJS, Los Angeles, Cal.; KOG, Los Angeles, Cal.; KFCL, Los Angeles, Cal.; KSL, San Francisco, Cal.; KLB, Pasadena, Cal.; KUY, El Monte, Cal.; KDPT, San Diego, Cal.

Medium DX—KMO, Tacoma, Wash.; KDZQ, Denver, Colo.; KDZR, Bellingham, Wash.; KDZL, Ogden, Utah; KFAU, Boise, Idaho; KFAJ, Denver, Colo.; KFDL, Denver, Colo.; KDYS, Great Falls, Mont.; CFAC, Calgary, Canada; KFHR, Seattle, Wash.; KFBL, Everett, Wash.; KDZE, Seattle, Wash.

Real DX—WMAQ, Chicago, Ill.; WOAI, San Antonio, Texas; WDAF, Kansas City. Mo.; WGAQ, Shreveport, La.; WFAY, Independence, Kan.; CFCA, Toronto, Canada.

Also get "oodles" of amateurs on 200 meters. On 800 the commercial stations crash in and rattle my diaphragm. Will answer all cards.

Not Half Bad—? Eh?

From Thornton Higgins, 7313 St. Lawrence Ave., Chicago, Ill.

I AM an interested reader of RADIO WORLD, especially the page devoted to the DX fans.

To date I have heard stations in 26 states and 2 in Canada. The set I am using is homemade, with one step of audio-frequency. The following are the stations heard:

CFCA, KDKA, KFDL, KLZ, KOP, KSD, KYW, WAAF, WAAP, WAAS, WAAW, WAAZ, WBAD, WBAH, WBAP, WBU, WBZ, WCAH, WCAE, WCAS, WDAJ, WDY, WEAB, WEAC, WEAF, WEAJ, WFAA, WFAY, WGAN, WGAK, WGAS, WGF, WGM, WGR, WGY, WHAK, WHAO, WHAS, WHAZ, WHA, WHB, WIAC, WIP, WJAX, WJAZ, WJZ, WLAG, WLAL, WLK, WLW, WMAQ, WMB, WMC, WMU, WNJ, WOAW, WOC, WOR, WOS, WOZ, WPAD, WPA, WQAA, WSAH, WSY. WSB, WTAS, WWAY, WWJ, WIAO. 2XI, 3XW, 9AB, 9AGN, 9BBG, 9BU.

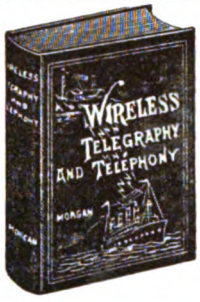
Radio Books for Your Vacation

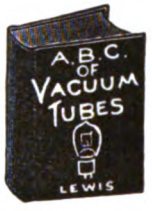
Telling How to Operate a Radio Set—How to Build a Set—Principles of Vacuum Tubes and Other Radio Problems



Wireless Telegraphy and Telephony Simply Explained

By ALFRED P. MORGAN

One of the most complete and comprehensive treatises on the subject ever published. A study of its pages will enable one to master all the details of the wireless transmission of messages. The author explains in simple language the theory and practice of wireless telegraphy and telephony. 154 pages, 156 engravings.....PRICE $1.50

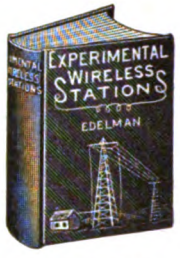


The A B C of Vacuum Tubes Used in Radio Reception

By E. H. LEWIS

Assoc. I. R. E., and Radio Instructor

Written particularly for the person who "knows nothing about radio," but who would like to gain an understanding of the elementary principles of operation of vacuum tubes and various circuits in which they are used for the reception of radio-telegraph signals and radio-telephone music and speech. Illustrated.....PRICE $1.00



Experimental Wireless Stations

By P. E. EDELMAN

Tells how to make apparatus to not only hear all telephoned and telegraphed radio messages, but also how to make simple equipment that works for transmission over reasonable long distances. Then there is a host of new information included. The first and only book to give you all the recent important radio improvements, some of which have never before been published. 392 pages, 167 illustrations....PRICE $3.00

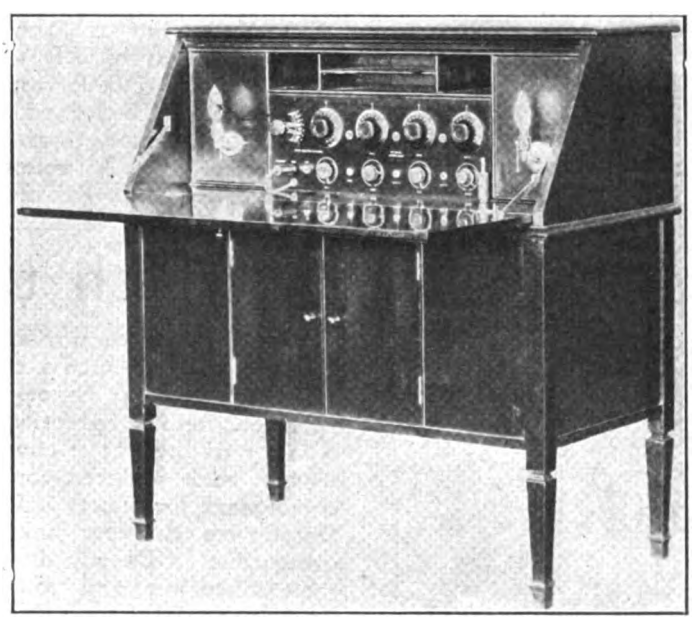
Tuned Radio-Frequency Amplification

By Leon W. Bishop, 1XP

RADIO-FREQUENCY amplification has been the subject of much discussion for ten years, but it is only in the last four years that we have been able to get good results on the shorter wave bands.

Fully 90% of the radio-frequency circuits employ transformers of fixed ratios for a given wave band and in some instances use iron to broaden the range. No matter what method you use to broaden the band with a fixed ratio transformer you still have one narrow band that is favored while the efficiency drops off rapidly on either side. Now that the broadcasting wave band has been widened we must turn to tuned radio-frequency amplification for real results which is the only logical method.

There is no need of a double circuit tuner when several stages of tuned radio-frequency are used and where a slight amount of regeneration is present. In Fig. 1 let the dotted line represent a given wave length and point A the tuning point of the single circuit. Now if the first tube is tuned to this exact point regeneration will occur, but a place on either side of A will be found where no regeneration occurs and the amplification is normal. The point C represents the tuning peak of the second tube and it may be seen that the relative positions of B and C may be reversed so as to minimize interference from local sources. The third stage is shown by D and is not critical of tuning due to the great amount of amplification delivered to it by the first two stages. However, a wide range of selectivity may be obtained by using this stage in connection with the second.



Set employing tuned radio-frequency, as described in the accompanying article, built for Mrs. F. A. Ball, of Athol, Mass., daughter of the late L. S. Starrett, tool manufacturer.

Fig. 2 shows one tuned stage of radio-frequency and detector. The variable condenser C is .0005 mfd. (23 plates). The tuning inductance L consists of 60 turns of No. 22 wire wound on a four-inch tube and tapped every 10 turns. V is a variometer and should be free from shellac on the windings. The success of this circuit depends upon the grid leaks and for that reason it is best to use a variable grid leak. The first grid leak GL is about one megohm, and the second or detector grid leak GL1 is about one-half megohm. The grid condenser C2 is of the mica type and .0005 mfd.

The high vacuum type of tube is best for the radio-frequency circuits while the standard type of detector tube is best adapted for the detector circuit. The B battery for the first radio-frequency tube should be from 45 volts up, and the detector voltage should be that amount recommended by the manufacturer.

The grid leak should be adjusted to the point where only a small path of regeneration occurs when tuning the variometer. A variometer may be used in the plate circuit of the detector tube with increased amplification—also increased tuning troubles.

Fig. 3 shows three tuning stages and detector. The aerial circuit is the same as that described in Fig. 2. The fixed condensers C1 are .001 mfd. and of the mica type. The grid leaks on the first and second tubes should be capable of adjustment as low as 10,000 ohms. A 300 or 400 ohm potentiometer P is connected across the A battery and the negative B battery returned to it. A separate tap is provided for the first stage of RF while the second two stages are connected to the same point on the positive B battery. As much B battery as possible should be used on the radio-frequency tubes up to about 130 volts. The proper amount is determined by trial. The phones should be shunted with a .002 mfd. condenser.

For those interested in power amplification Fig. 4 shows three stages of radio-frequency and two stages of audio-frequency amplification. The radio-frequency part of the circuit is the same as that shown in Fig. 3. The fixed condenser C3 is .002 mfd. The point X should be connected to the negative side of the filament and not to the negative side of the A battery.

Fig. 5 shows a neat and inexpensive charging arrangement for any panel. Care should be taken to use metal covered cable for the AC circuits.

(*Concluded on next page*)

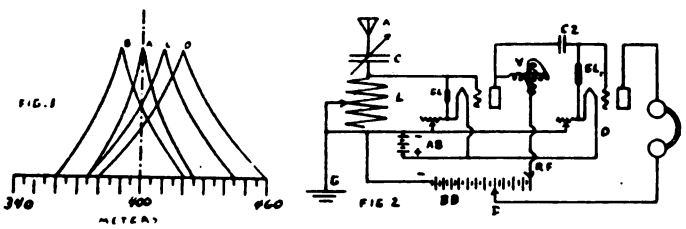
Digitized by Google

(*Concluded from preceding page*)

Fig. 6 shows an outline of the panel which is 28 x 8 inches for those wishing to follow the design.

The results obtained with this circuit depend upon two points—first, the adjustment of the grid leaks; and second, your knowledge of tuning.

201-A tubes are the best for all of the amplifiers, and may be used for the detector but the old standard detector tube with proper plate voltage seems to give the best results. When distance (DX) is the object the tap on the first RF tube should be lowered but when volume is desired this tap should be moved up on the B battery.

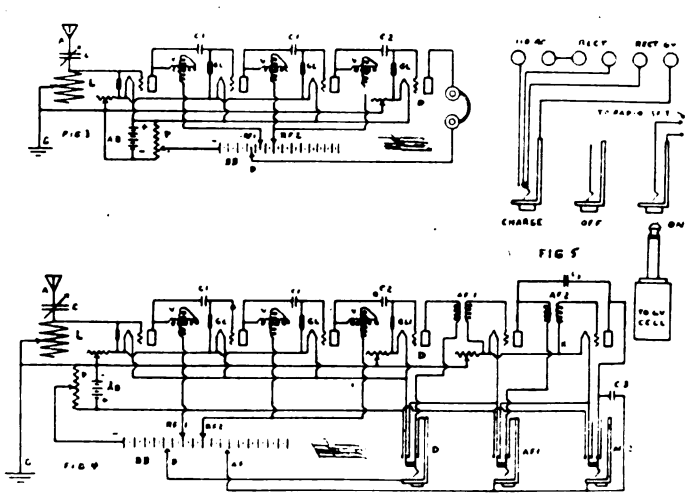


Figs. 1 and 2. Showing the advantage of using tuned radio-frequency and circuit diagram of a two-tube set employing one stage of tuned radio-frequency amplification with tube detector.

The dials should be set to correspond with the variometers; that is, the dial should be at zero when the variometer is at minimum as readings obtained on various stations have a meaning and the same station will always appear at a given point providing the values of the grid leaks have not been changed in the meantime.

As much B battery as possible should be used on all tubes up to about 140 volts for maximum results.

When the circuit is first used regeneration will run wild, but this can be controlled by decreasing the grid leaks. The leak on the second tube is most critical and is always the lowest, sometimes in the order of 10,000 ohms. As the leaks are decreased tuning becomes broader but it is advisable to have a path of regeneration on the first variometer. When regeneration enters into this circuit it comes on with a bang and all signals stop. The greatest signal strength is obtained on either one side or the other of this regenerative point.



Figs. 3, 4 and 5. Sets employing three stages of tuned radio-frequency amplification with detector, and also with two stages of audio-frequency. A neat panel charging device is also illustrated.

Once a rough setting of the grid leaks is obtained the third variometer dial can be set at 75 and the second dial at 40, tuning the first variometer and aerial condenser to a given signal using both hands in the operation. The tuning may be finished up by a final setting of the second and third variometers.

The most active part of the first variometer dial is the first eighth of the dial; the second variometer the middle half and the third is active over the last half. This is a given normal condition but many variations may be tried that are more selective.

Wherein points of regeneration may be found in this type of tuner it must be remembered that it is not classed with the common species of renegerative set that produces untold interference in the neighborhood.

This circuit is taken from old British practice of reactance capacity coupling and remodeled to suit our present broadcasting reception.

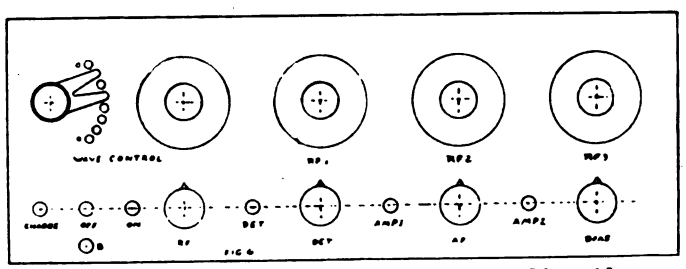


Fig. 6. Panel layout suggested for the sets described herewith.

This circuit is designed for use with a loud speaker on distance reception as well as local. Stations 1,500 to 2,000 miles away may be reproduced in the loud speaker with wonderful volume and no distortion.

Indoor types of aerials may be used with success and loops for local work.

This set greatly reduces interference (QRM) from local stations as well as static (QRN).

The following are the references covered in the diagrams: A aerial, AB A battery, AF audio-frequency, BB B battery, C .0005 variable condenser, C1 .001 fixed condensed, C2 .0005 fixed condenser, C3 .002 fixed condenser, D detector, G ground, GL grid leak, GL1 detector grid leak, L tuning coil, P potentiometer bias, RF radio-frequency, V variometer.

Watch the Details

IN the construction of a receiver the builder is generally in such a rush to get the set made and working that he neglects to think of minor details that help in reception. Do you ever think of the polarity of the phone connections? Do you ever stop to test each soldered connection? Do you test your condensers for shorts before putting them in the set? Do you see that your jacks and plugs are perfect before using them? Do you do a hundred other little things such as brushing and blowing the little filings and chippings out of your condensers and wiring? Think it over, and don't blame the set when you have to hunt for "Old Man Trouble."

A Handy Hint

CONDENSERS like everything else that is subject to much use, occasionally lose their friction control and will not stay set, but slip around. If you attempt to tighten them by the use of the friction screw there is a liability of shorting the plates. If instead, you remove your dial and put a washer of felt or cork between the dial and the panel, fitting it carefully over the shaft, you can get any desired amount of friction—and you won't have to bother with tightening any screws.

A Crystal Set—Cheap, Compact and Efficient

By Kenneth Malcolm, A. I. R. E.

THE person who lives in the vicinity of a transmitting station can reap the benefits of radio broadcasting without any great outlay of money. The solution of the poor man's radio is found in the crystal set. Of course, the crystal set has its limitations, but it also has advantages that are too often ignored by the present generation of fans, and the popular magazines. But here and now it might be mentioned that the crystal detector is the most efficient detector used, when it is considered that there is absolutely no local or battery current employed in its operation. Crystals are not very sensitive, comparatively, and they are sometimes difficult to keep in adjustment; but notwithstanding this, they afford a simple and effective means of bringing the broadcast concert into the homes of those of moderate means, who cannot consider any great expenditure.

The set to be described can be made at home, with little trouble and small cost, and will operate very efficiently for a set of its type. The writer operated such a set in Brooklyn, N. Y., and brought in all the local stations, including those in New York City and Newark, very distinctly and with considerable volume.

There are not many parts to buy, so it would pay to buy the very best; for the improved results will surely be commensurate. Apart from the set itself, the receivers, or 'phones, are a very important item. Try and get the most sensitive that you can afford.

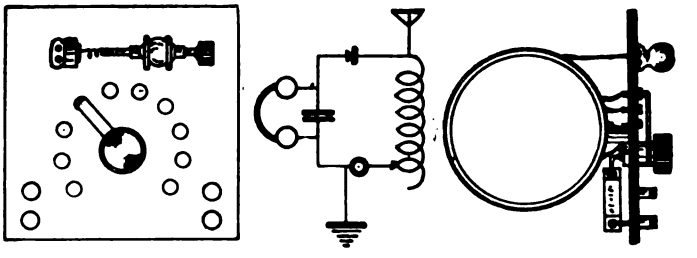
The panel is 5½ inches square and ⅛-inch thick, and of some of the recognized insulating materials. The parts for the detector may be bought at some radio store or supply house, or else they may be detached from the base of a mounted detector. The tube for the tuning coil may be of cardboard that has been impregnated with insulating varnish, vulcanized fibre, hard rubber, or one of the phenol condensation products—preferably the latter; and 3½ inches long and 3½ inches in diameter. About a half pound of No. 24 cotton covered wire is needed for the winding. Procure a small rotary switch of some sort and ten contact points or taps. A fixed condenser of .001 or .002 mfd. capacity is necessary for use across the phone terminals. In buying this it is best to be on the safe side by getting one with a mica dielectric; for the paper dielectric type are in many cases unsatisfactory, on account of their hygroscopic qualities and their changeable capacity, varying with pressure. The difference is not noticed so much, however, in this particular point of operation as in other parts of a circuit. A cabinet, connecting wire, and four binding posts, complete the list of necessary materials.

If your panel has a glossy surface, and you wish a dull finish, it is best to rub it down before mounting the instruments. Some very fine sandpaper, or better still, steel wool, will soon take off all the shine. Do not use a criss-cross or circular movement in rubbing, but rub back and forth in one direction. After the panel has been laid out, and the instrument holes drilled, the final finish of a rich dull lustre may be given by a rubbing with a piece of cotton waste, or an ordinary rag, dipped in machine oil, the superfluous oil being rubbed off with a dry cloth.

Now accurately lay out the panel for the various holes for the switch arm, taps, binding posts and detector. If the panel is to be mounted in a cabinet, holes should also be drilled for the fastening of screws. It might be well to first lay out the different points on a piece of paper of the exact size of the panel; when complete and satisfactory, transferring them direct to the panel. A sharp center punch should be used in marking the points for holes, serving both as a marker and as a guide for the drill tip.

The tube may be mounted to the panel by means of two little brackets made of brass strip, or by means of a small brass tube passed over a long screw, as shown in the drawing; one tube and screw is used on each end of the tuner.

Before being mounted, the tube is given a coat of insulating varnish, and 80 turns of the No. 24 wire is smoothly wound on. There will be about a half-inch left at each end of the winding. Taps are taken from every eight turns. If the wire has been wound tightly enough, the coil will not need another coat of varnish; it is really better without it. Short flexible leads should be soldered to each of tapping points.



Front view of the completed crystal set, circuit diagram and side view, showing the method of fastening the tube to the panel and the arrangement of the leads.

The instruments may now be mounted on the panel. Before the tuner is permanently attached, it is best to solder all the little leads to the switch points. All the other joints should be soldered, also, for every effort should be made to preserve the minute currents that are available in a receiving set. A soldered joint in time means the saving of having to take your set apart nine times in the future.

Except for the tap leads, the connections may be made with rigid wire. No. 14 bare aerial wire is good for this purpose, and ordinary annunciator wire will do in a pinch. If bare wire is used, make sure that there is no possible way for crossing wires to touch and cause a short-circuit; and if a wood box is used, try to keep the bare wires from making a direct contact with the wood.

With a good crystal in the detector, the set is now ready for operation. As a personal preference I would choose galena. For, though it is not always stable, it is very sensitive; that is, providing it is a good piece, for specimens of all crystals vary considerably in their rectifying properties.

The binding posts at the left of the panel are for the aerial and ground connection, and the two posts on the right are for the phones.

The operation of the set consists simply in locating the sensitive spot on the crystal, and moving the switch over the various switch points until the station wanted is obtained.

Radio Signals of Standard Frequency to Check Wave Meters

THERE is given below a schedule of standard frequency signals to be transmitted from the Bureau of Standards at Washington (station WWV). These signals should be of interest to all station operators who transmit on frequencies above 425 kc as they may be used for checking wavemeters and adjusting transmitting and receiving apparatus. Their accuracy is better than three-tenths of one per cent. Information regarding the use of these signals was given in February, 1923, issue of the Radio Service Bulletin. More detailed information is given in Bureau of Standards Letter Circular No. 92 which may be obtained on application to that bureau.

Commercial and ship stations should be especially interested in the 425, 500, and 600 kc waves. The 425 kc wave is the new frequency assigned by the Department of Commerce for commercial ship traffic. The remainder of the schedule includes the frequencies used by broadcasting and amateur stations. The transmission on the morning of October 7, is especially for amateur stations and includes only frequencies used by them. It will be helpful if amateur operators will stand by while the standard frequency signals are being transmitted on this date, so there will be as little interference as possible with their general reception.

In the schedule below the "general call" is given by voice during the first half of the four minute period and by continuous wave telegraph during the second half; this call is given to enable listeners to tune in WWV. The "standard frequency signals" consist of the station call letters WWV repeated with very long dashes intervening and are transmitted by unmodulated continuous waves. The "announcements" are made by voice during the first half of the period and by CW telegraphy during the latter half. The general call and the announcements are made on the same frequency as the standard frequency signals and may be used for some measurement purposes, but it is recommended that accurate measurements be made on the standard frequency signals only. With highly sensitive receiving apparatus it should be possible to receive these signals anywhere east of the Mississippi River.

Schedule of Standard Frequency Transmission from WWV

Eastern Standard Time	Signal	Kilocycles (wave length in meters) July 17	Aug. 15	Sept. 13	Sept. 28
10:55 to 11:04 p.m.	General call	425	425	425	500

Radio Amateurs Aid Victims in Oklahoma Flood

SAND SPRINGS, Oklahoma.—Sticking to their radio sets for three days and nights during the unexpected rise of the Arkansas River, radio amateurs in this vicinity recently maintained communication between here and Tulsa when floods swept a large section of Tulsa County. Fully 500 people were driven from their homes and thousands of dollars damage was caused by the high water which put wire lines out of commission.

The towns are connected normally by an electric interurban road, four telephone lines and the telegraph line, but all were down except the latter and one telephone line. Most of the flood victims, whose homes had either been destroyed or made uninhabitable, were housed temporarily at a park here and fed until the water began to recede. Meanwhile scores who frantically besieged local telephones had to wait three hours before they could get a call although the distance is only seven miles.

Halton H. Friend, a member of the American Radio Relay League, offered to send messages through by radio, also bulletins on the rise of the river for the daily newspapers at Tulsa. He got in touch with Raymond U. McKinney, 5SG, John B. Lewis, 5WX, at Tulsa, and Earl W. Abrey, 5GA, at Osceola, Ark. The first night they kept fifteen minute schedules until 2 A. M. and the next two nights forty minute schedules until after midnight for the emergency.

Scores of personal messages were sent relieving the minds of relatives of those who had lost their homes. Amateur stations were also utilized by newspaper reporters who were unable to use wire lines on account of the limited service.

Important but Neglected

MANY single circuit sets could be improved over 50% by the use of a potentiometer in the filament-grid circuit. The control of the set is made a little more difficult, but the results gained will more than pay for the added trouble.

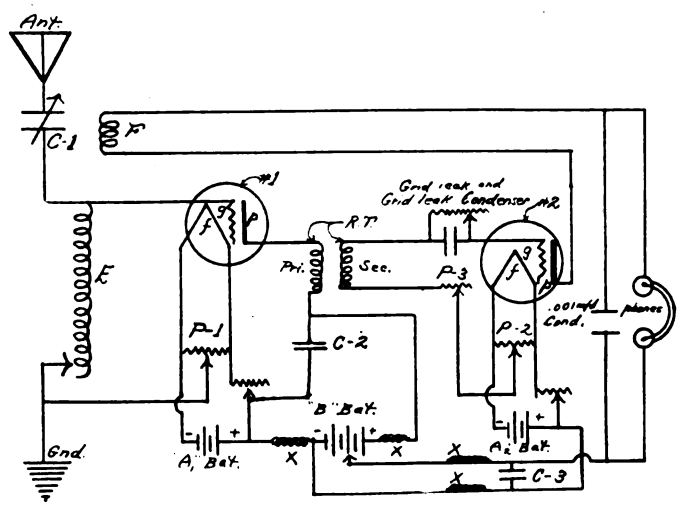
Radio-Frequency and Regeneration Combined

By C. White, Consulting Engineer

RADIO-FREQUENCY amplification and regeneration is going to be just as popular in the near future as the single circuit regenerative tuner is today. For the past year radio-frequency amplification and regeneration have only been considered as two separate and distinct methods of radio reception. The former was considered ideal since it was very quiet, but the latter proved to be more efficient and popular because more could be done with one tube using regeneration than by any other known method. It has been a battle of smooth and quiet operation versus economy and compactness. No one ever thought of combining the two on a commercial scale nor did any amateur ever think it was advisable to tackle; it either meant that he would have a radio-frequency outfit or a regenerative receiver, and not a combination of the two. But conditions have favorably changed on the radio market and parts which were not readily obtainable for amateur use are now to be had at almost any radio supply store. These parts are namely large size paper condensers, often called telephone condensers, and radio and audio-frequency choke coils. The coming of the UV199 tube has materially aided the accomplishment of the feat since it is now possible to operate a multiple tube outfit much cheaper than it was to operate one of the older types of tubes. Then again, with the past year we have changed some of our hard and fast ideas in regard to detectors and, in reality, it is this change of ideas that has made it possible to use low filament current tubes. Heretofore we have considered a soft or gaseous tube as the only one that was capable of use as a detector. Still the gaseous tube was not only more difficult to manufacture with uniform quality but required quite a high consumption of power to operate its filament at the correct temperature. It was also very erratic and critical requiring quite a bit of skill to handle it successfully. This idea has been thrown to the winds for all the new series of tubes are hard or high vacuum tubes. These tubes when used correctly in a circuit give very much clearer and louder volume than the old type of detector, but they must be used correctly.

The circuit illustrated herewith is the old reliable and simple single circuit regenerative receiver with one stage of radio-frequency amplification. The choke coils X are absolutely essential to the correct operation of the set. These choke coils which are .1 henry inductance act together with the bypass condensers C-2 and C-3, thus forming a sort of filter arrangement that effectively blocks out radio and audio-frequency currents from passing through the common "B" battery, thereby preventing serious leakage and coupling. The condensers C-2 and C-3 should be paper condensers of 1.0 micro-farad capacity apiece. The potentiometers P-1, P-2 and P-3 should have a resistance of 400 ohms apiece, and, in order to prevent noise in tuning it is better to get the carbon pile resistance units, since wire units do not make it possible to smoothly vary resistance from a minimum to a maximum. The condenser C-1 must be a well insulated 23 plate air variable with a vernier attachment or plate. The main tuning coil and tickler feed-back coil is the unit E-F which is a good 180 degree coupler, using the coil F as the rotor and the coil E as the stator tuning inductance. Failure of the circuit to regenerate properly will most likely be due to the fact that the tickler is connected in the circuit backwards, which condition is easily cured by reversing the wires connected to the terminals of the tickler coil. The other parts of the receiver are self-explanatory and can be ascertained from the standard symbols used on the schematic diagram. For portability and economy of operation I recommend the new radiotron UV199, although the circuit will operate with almost any type of hard amplifier tubes.

This receiver is especially designed for the amateur who has already in his possession a single tube regenerative receiver and wishes to add some radio-frequency amplification as well as make some changes



Schematic diagram of a circuit combining the old reliable single circuit regenerative receiver with one stage of radio-frequency amplification.

in his outfit. There are several special features on this receiver that will appeal to the advanced amateur; namely, the use of potentiometers rather freely. It might appear to be a waste of apparatus to do so, but if you will stop to consider the trouble that it prevents the outlay is readily justified. By the practise of adjusting these potentiometers you can readily learn to get maximum volume without causing the tubes to oscillate or spill over at the most sensitive spot. After tuning in you can always improve volume as well as quality by carefully turning these potentiometers. Do not use a high "B" battery potential on the detector tube (No. 2) because its action is very much better even when less than 20 volts is employed. But, on the amplifier (No. 1) as high as 80 volts can be used without impairing quality. A good make of radio-frequency amplifying transformer (R. T.) is used. The builder of this receiver is warned not to have too many turns on the rotor or tickler coil F. In fact, when this type of regeneration is used with radio-frequency you cannot critically feed-back as though no radio-frequency were employed. Connect the movable plates of the condenser C-1 to the antenna, and use a variable grid leak with a grid leak condenser of .00025 mfd. capacity.

It is, of course, rather difficult to guarantee any definite mileage for this receiver, but on try-out using only a small 20 foot indoor aerial 2,000 miles was obtained with ease and clarity that was truly remarkable.

An Extra Super-Sensitive Receiver

By A. E. Herron

THERE has been much said and written about super-selective and super-sensitive receiving sets, but nothing has really developed as yet that would eliminate the carrier waves, noticed as whistles and squeals from one station when listening to another when the two stations are on nearly the same wave length.

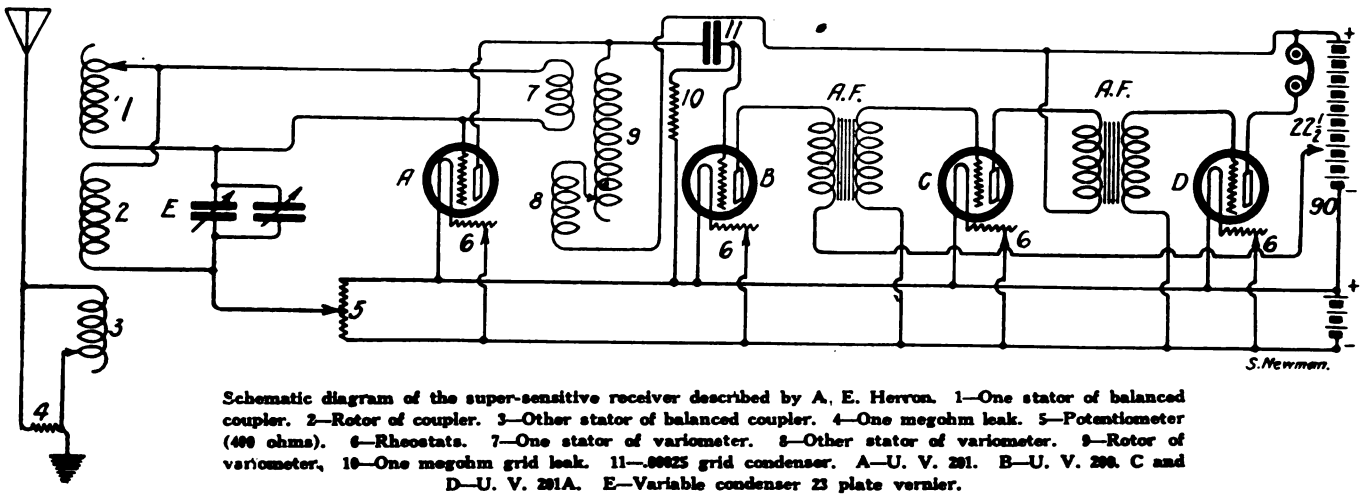
Of course, many times, especially in the cities, squeals or whistles will be heard which are due to some local receiver oscillating. These cannot be eliminated without the help of the operator of the oscillating receiver.

Whistles and squeals caused by stations being almost on the same wave lengths can be eliminated, provided there are at least four meters difference, and if both stations are not locally situated.

Every circuit imaginable was tried out (except the super-heterodyne) and none proved as selective as the one shown, which was so selective that with but one degree of variation on the coupler dial the loudest station could be completely tuned out. Even with the two plate vernier condenser a station could be tuned completely out with but two degrees on the dial. The best parts obtainable were used in making this set.

It is absolutely necessary that the windings of the variometer and coupler be connected correctly or else the set will not function properly.

The top binding post which connects with the left hand stator of the coupler is connected to the ground and the aerial connection is taken off at the switch arm. The top post of the right hand stator of the coupler is connected to the upper post of the rotor and also to the top post of the left hand variometer stator. The lower post of the left hand variometer stator is connected to the grid of the radio-frequency tube and also to one side of the variable condenser and the lower stator post of the right hand coupler. The lower post of the coupler rotor is connected to the opposite side of the variable condenser and also to the potentiometer. The lower post of the variometer rotor is connected to the plate side of the radio-frequency tube. The upper post of the rotor is connected to the lower post of the right hand variometer stator. The upper post of the right hand variometer stator is connected to the positive side of the amplifier "B" battery. The rest of the connections are simple and are made according to the diagram.



Schematic diagram of the super-sensitive receiver described by A. E. Herron. 1—One stator of balanced coupler. 2—Rotor of coupler. 3—Other stator of balanced coupler. 4—One megohm leak. 5—Potentiometer (400 ohms). 6—Rheostats. 7—One stator of variometer. 8—Other stator of variometer. 9—Rotor of variometer. 10—One megohm grid leak. 11—.00025 grid condenser. A—U. V. 201. B—U. V. 200. C and D—U. V. 201A. E—Variable condenser 23 plate vernier.

This set has been in operation aboard S. S. "Collingwood" on the Great Lakes for some time. The set is absolutely noiseless in operation—in fact if it were not for the sight of the glowing tubes one would think it was a crystal set he was listening with.

Tuning of this set is very simple once the action of it is understood. When first tuning the condenser is left at about twenty degrees, then the rest of the tuning is easily done by means of the coupler and variometer using the vernier condenser for fine adjustment. Both variometer and coupler must be varied at the same time when tuning. The coupler and condenser are used for varying the wave length and the variometer and potentiometer are used for controlling the volume. The variometer must be left at the point where a click is heard in the 'phones. If left any distance from the click it will tune broadly or the station may not be heard at all.

A vernier rheosat should be used in the detector and radio-frequency tubes although not absolutely necessary.

If a series condenser is used in the aerial circuit a one megohm leak should be connected across the aerial

(*Concluded on next page*)

The parts necessary for the construction of this set are as follows:

One Kellogg variometer, one Kellogg variocoupler, one 23 plate vernier variable condenser, two Federal audio-frequency transformers, two C. H. rheostats plain for U. V. 201 A, two C. H. rheostats vernier, one C. H. potentiometer, two double sockets, one grid leak and condenser, three Federal jacks, two switch arms and knobs, three dials, 6″x23″x½″ base board, one 8″x24″x¼″ Bakelite panel, two brackets.

U. V. 201 Radiotrons were found to be better than the new U. V. 201 A as radio-frequency amplifiers. A U. V. 200 was used for detector and two U. V. 201 A tubes were used for audio-frequency amplification; 90 volts were used on the plate on the amplifiers and from 16 to 22½ on the detector.

The writer used a Kellogg variometer and variocoupler in this set, with an extra binding post added on top of the variometer and coupler so that the wires which connect the two stator coils could be separated and the end of each could be brought to a separate binding post. By doing this both stators could be used separately as shown.

An Improved Turnbull DX Loop Receiver

By A. D. Turnbull

AFTER having received many letters from fans and friends as to the wonderful results obtained by the use of my circuit published in RADIO WORLD for May 19, and quite a few questions relating to whether or not this circuit could be accommodated to a loop I finally decided to evolve one for them with the results shown below.

Before giving information as to the construction of the receiver, a few words as to the tubes used will not be amiss. I have done all my work with the Canadian R-215A tubes, which are dry cell tubes similar to the popular dry cell tubes that you are accustomed to using. I have found that as good results could be obtained with these small tubes as with any others—if the set is properly tuned. Contrasting the work of both the six volt tubes and the 1½ volt tubes the difference if any is so slight that I myself could not detect it unless I measured it with resistance bridges and galvanometers, and even in that case there was but very little variation. This goes to show that the important thing in the operation of a set is not the tubes used, but how the set is tuned and how the operator constructs his set.

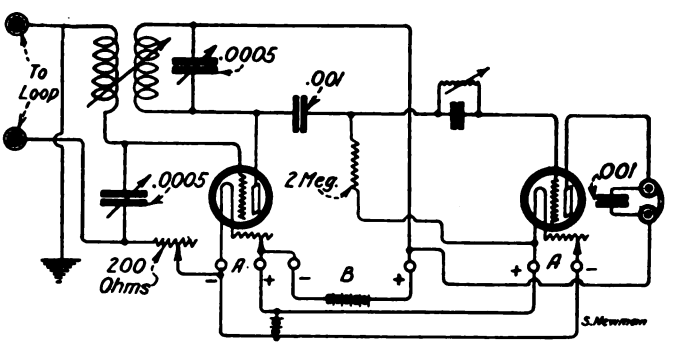
By looking at the present set and comparing it with the original diagram, but little difference can at first be noted. The technical points of the circuit remain intact except for some few changes, such as a potentiometer in the filament-loop lead, which acts as a stabilizer and permits very fine control of the regeneration and tuning. Of maximum importance is the coupler. It is much better to have a coupler that is capable of fine tuning than to get one of the bank wound type that will cause you no end of trouble through distributed capacity and dead-end losses.

The condenser capacities in the plate grid lead of the two tubes are of major importance and no other capacity will give the proper results. Of particular importance also is the two megohm grid leak in the grid circuit of the second tube, leading from the filament side of the tube to the plate-grid condenser.

When tuning in the set it will be noted that super-regenerative action ensues when the coupling of the tickler is tightened, and when this reaches a certain point, the amplification is enormous, but this must be done very cautiously, otherwise the set will howl like a cat that has been trod on. On account of this it is best to have the rotor of the coupler wound with coarser wire than is usually the case, and about 35 or 40 turns at the most.

A good ground to the grid lead side of the loop is essential to the proper operation of the set, and as queer as it may seem the reception and tuning will improve 100% when a good ground is connected. For those who do not happen to have a coupler handy, good results may be had by the use of honeycomb coils. For this purpose a coil of 50 turns for the primary and 35 turns for the secondary will do. If lower waves are desired, a 35 and a 25 turn coil can be used.

With this set operated properly and the tuning systematically done wonderful results will be accomplished, but the builder will have to become acquainted with his circuit before he obtains the best results, but as the tuning controls are quite simple it should not prove a difficult circuit for the fan to handle.



The original Turnbull receiver adapted to loop reception. Note the ground connection to one side of the loop.

As to distances that this receiver will work over, it can be said that stations 2,200 miles distant were received with perfect clarity and freedom from noise, all of course depending upon the existing conditions at the time of reception.

(Concluded from preceding page)

and ground. This will prevent the aerial from charging if a transmitter is used as it will discharge through the leak instead of sparks jumping the condenser. This leak will not have any effect on the signal strength. When constructing the set be sure to buy the best material obtainable. Be sure that every connection is properly soldered. Tinned bus bar wire should be used for connecting the different instruments. A very great percentage of the efficiency of the set depends on the tuning. If it is thoroughly understood what each part is for no difficulty will be experienced in getting good results but even the very loudest stations will be missed if it is not tuned slowly. Take your time in tuning, and in a short while you will understand the action of the set and tuning will be very simple.

Any one undertaking to build this set will be amply repaid for his patience and trouble as, when properly constructed and operated, it will give marvelous results both in selectivity and long distance reception.

Think This Over

COULD you go out and get an automobile and learn to run it in a day by means of a book of written instructions? No—unless you were a super-man. Could you lay bricks without the knowledge of how it is done? Could you learn from printed instructions? No.

Then why do you think you can learn to tune your set by merely reading about it? Go to it and learn by experience. Your set may be turned out in hundreds from a factory, yet it has its own little twists and twirls, and individuality. You have to get the feel of it first and it may take a week or two before you can even tune in the local stations correctly.

Therefore do not get impatient and yell for assistance. Go to it and learn by doing. If you find out that your set works best when the potentiometer is at 50 and the printed instructions say that it should be at 75, leave it at 50, and consider that you have put something over on the maker of the set.

New Regulations Benefit Amateurs

WASHINGTON, D. C.—The Department of Commerce has authorized a broader band of wave lengths for general and restricted amateur radio stations, and created a new class of amateur operator's license to be known as Amateur Extra First Class. The new regulations sent to all District Supervisors of Radio read:

Supervisors of Radio and Others Concerned:

Licenses will be issued permitting the use of any type of transmitter (CW, Spark, AC-CW, ICW, unfiltered CW and phone) with the restriction that when using pure CW they are authorized to use wave lengths from 150 to 200 meters and when using spark, AC-CW, ICW, unfiltered CW and phone the wave lengths from 176 to 200 meters only can be used. The types of transmitters must be specified in the application and the license.

Special Amateur Radio Station Licenses will be issued permitting the use of pure continuous wave transmitters only, authorizing the use of wave lengths from 150 to 220 meters.

For the purpose of application to amateur stations, pure CW is defined as follows: A system of telegraphing by continuous oscillations in which the power supply is substantially direct current as obtained from (1) a generator, (2) a battery, or (3) a rectifier with an adequate filter. (A filter is not deemed adequate if the supply modulation exceeds five percent.)

General Restricted and Special Amateur Stations are not permitted to use a transformer input exceeding one kilowatt, or equivalent of this power based upon watt input to plates if tubes are used. (When input rating of tube is not specified by manufacturer this rating will be considered as double the manufacturers output rating.)

On licenses issued for amateur stations you will include the following: "This station is not licensed to transmit between the hours of 8:00 and 10:30 P. M., local standard time, nor Sunday mornings during local church services."

Special Amateur stations must be operated by persons holding an extra first grade amateur operator's license, or a commercial first class operator's license, or a commercial extra first class operator's license. Applicants must also meet the requirements of Regulation 63.

A new class of amateur operator's license is hereby established to be known as "Amateur Extra First Grade." Licenses of this grade will be issued to persons passing the required special examination with percentage of at least seventy-five and code speed in sending and receiving at least twenty words a minute, five characters to the word; who have had at least two year's experience as a licensed radio operator; and who have not been penalized for violation of the radio laws subsequent to the date of these regulations.

Respectfully,
A. J. TYRER,
Acting Commissioner.

Approved:
S. B. DAVIS,
Acting Secretary of Commerce.

The Radio Woman

THE Editor has shown me a letter from Miss May Clough, of New York State, who encloses a check for a renewal of her subscription for RADIO WORLD and in which she says: "I appreciate the paper very much and greatly enjoy keeping up with the new developments and news of radio. I have constructed the Sorensen set, described in your issue of January 20, using a U. V. 199 tube, and it proves very satisfactory. Your last number gives me an idea and I am going to replace the variocoupler arrangement with a coil mount to facilitate changing coils."

This is a fine letter and I'm tickled to death to hear from a woman radio enthusiast. I would like every woman who has built a set to write and tell me her experiences.

* * *

Granny Tector recently made one of her long-promised trips down from the farm to see us. I guess it is nearly four years since she was here last, and she is the dearest thing ever. Even though four score and seven years old, she boasts the fact that she has never missed a single Sunday at church. Out where she lives it is a two hour ride in the "buggy" to church, but that doesn't detain that dear old lady. Seeing as how we were getting ready for a picnic in the woods that afternoon, we thought that we would take our church via radio, and accordingly made our plans. Granny prettied up and waited patiently for us to start, and when we told her that we were going to church by radio she was all a-flutter, but later on after she had sat through the entire service with a pair of phones on her ears she remarked in a quavering voice, "Well, I never! I often heard tell of 'tending meetin's' by proxy, but this is the first time I ever thought of being in church by turning on a light."

* * *

That afternoon we went out in the woods, of course, taking our set along with us, and turned on the beautiful organ music from one of the big broadcasters. She listened intently, often following the well known strains by humming in a high pitched voice, and after we had turned it off and started back home, she insisted that we must take her out and get one of those. "It'll be such a help to pa now. You know he still has rheumatics, and that two hour ride to church doesn't help him digest his Sunday dinner any—and I suspect that he sleeps in church anyhow, and this will keep him from sleeping, 'cause I can set right opposite him and keep him 'wake."

Try This on Your Set

SOME time or other in the life of the average radio fan, he hears some little weak station which is just beyond the range of audibility. He knows it is there and can very faintly distinguish music or voice but he cannot bring it in. He fiddles, fusses, fumes and curses, getting gradually hot under the collar. Eminent scientists tell us that getting mad is very injurious to the liver and should not be indulged in.

The next time that you hear one of those "whispering stations" instead of getting sore, just place a crystal detector in your grid lead between your grid condenser and the tube, then turn on your tube, find a sensitive place on the crystal and try and get him again. You will be surprised to find the station that whispered before is plainly audible now. You may not notice much change in volume in local stuff, but for distance it is just the thing.

Transformers in Theory and Practice

By Charles Byrnes, A. I. R. E.

TO the uninformed mind, transformers are little double coils with or without an iron core, that are put in the circuit because the diagram calls for them. Some people credit them with amplifying signals, and others have gone even so far as to accuse them of changing an alternating current to a direct current. In reality they do neither, but serve to change an alternating current from a higher to a lower or from a lower to a higher voltage. In the first case the current is increased, in the second case the current is decreased, and each in direct proportion to the decrease or the increase of the voltage.

A transformer usually has two distinct windings which are not connected to each other in any way, except through magnetic lines of force. The resistance of the magnetic circuit is reduced, in low frequency work, by the presence of an iron core. Transformers for very high frequency, however, have no cores other than air. The winding at which the current to be transformed enters is called the *primary* and the other winding is called the *secondary*.

The theory of the transformer is based on the theory of coils of wire in a changing magnetic field. In a given field, the greater the number of turns of wire the higher the voltage and the lower the amperage will be across the terminals. If one coil, energized by an alternating E.M.F., is allowed to act upon another coil within the field, it will be found that the voltage and amperage of the second coil will be in direct proportion to the number of turns which it includes, in relation to the number of turns in the first coil.

As an illustration let us assume that the primary coil is wound with 100 turns, and the secondary coil with 1,000 turns, or ten times as many turns as are in the primary. We exert an alternating pressure of 10 volts on the primary with a current strength of five amperes. If the transformer was 100 per cent. efficient we could expect a current of .5 of an ampere at a pressure of 100 volts in the secondary. If the number of turns was reversed and there were 1,000 turns on the primary and 100 turns on the secondary, we could expect a voltage of one, and an amperage of 50 at the secondary.

To impress the relationship more clearly we can find an analogy in mechanics that is first rate. Let us belt together two pulleys, as shown in the accompanying drawing, the larger pulley to be just twice the diameter of the smaller. If a turning force of 10 pounds is applied to the large wheel, which revolves at the rate of 100 revolutions per minute, a turning force of five pounds may be had from the small wheel, but at a rate of revolution of 200 a minute. That is, of course, assuming that the belt transits the entire enery without loss.

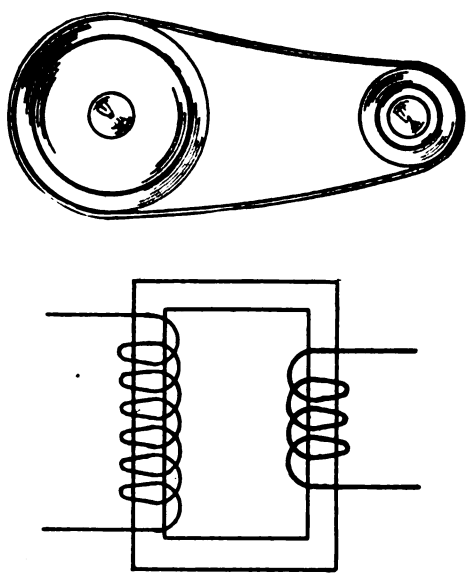
If we now link turning force with voltage, and revolutions with amperage, we have a parallel in the action of a transformer and the action of belted pulleys. The larger the wheel, in proportion, the greater the turning force and the lesser the speed. The greater the number of turns, the greater the voltage and the lesser the amperage; and vice versa.

In transforming energy of any kind 100 per cent. efficiency can never be attained; and this also applies to electrical transformers. One form of loss is called copper loss, which is occasioned by the resistance of the wire. Another is core loss, or *hysteresis*, which results from the inability of the molecules of iron exactly to follow the rapid alternations of the current to which a transformer is subjected. Ninety per cent. efficiency is considered very good in actual practice.

Transformers are usually used in receiving work in connection with vacuum tube amplifiers. They do not act as amplifiers themselves, but merely step up the voltage of the plate circuit of the preceding tube, or in some cases act simply to create two separate circuits, dividing the detector from the amplifier. Where the step-up principle is used, the increased voltage applied to the grid of the amplifier tube controls a relatively larger current in the amplifier plate circuit.

Practically the same action takes place in the radio-frequency air core transformers. Loose couplers and variocouplers are forms of air core transformers. Also, high frequency coils of the Tesla and Oudin types work on the same principle.

Larger iron core step-up transformers are used in spark transmitting stations to produce the high voltage necessary to jump the gap and charge the condensers.



Analogy between two pulley wheels of different diameters and the two coils of a transformer.

Still larger ones are used on alternating current transmission lines. By this means the voltage can be boosted and the amperage reduced with the result that a very large power can be sent out over comparatively small wires. There are step-down transformers at certain distributing centers, where the voltage may be cut and the amperage boosted for local consumption.

Step-down transformers are sometimes used in radio receiving work, to cut down the house current before going into the rectifier which supplies the current for vacuum tube filaments. Step-up transformers are used in the same manner to supply the plate current for transmitting tubes.

Beware of Oil Cloth!

Do not use oil cloth as a covering for your radio cabinet or as a cover for the table on which the set stands. Oilcloth holds atmospheric charges and will cause numerous clicks in your set. Silk has the same properties and should not be used to clean rubber panels or cabinets. The best material for this purpose is a soft woolen rag duster or feather duster.

Radio and the Traveler of 1930

By Solon Crane

IT is the year 1930. Our home is in New York. We are about to take a trip around the world.

There is not the usual excitement and flurry preceding the date of sailing as steamship passage, stateroom accommodations and the many other attendant details have all been arranged beforehand by radio. Our passport has been secured on unusually short notice, due to verification and endorsement from Washington via the ether waves.

Wireless power transmission has been achieved. Our ship carrying us across the ocean is electrically propelled—receiving its power from a mammoth transmitter located on the mainland. We are guided safely past rocks and shoals by the warning signals sent out from radio-controlled sirens and lighthouses.

The second day at sea we receive a message stating that reservations have been made for our accommodation in a Paris hotel. The equipment of the vessel permits us to carry on telephonic conversation, en route, with friends in London, Paris, or New York. This is most convenient, as little matters of unfinished business may be consummated very satisfactorily; in many cases saving a disagreeable loss, both in time and money. The great expanse of water surrounding us does not disconnect us from the life of our home country, for news is constantly coming in over the invisible waves.

The evenings on the boat offer all the livelihood of the city and there is entertainment for all classes. To the aesthetic group comes the opera, "Pagliacci," as it is being broadcast from the Metropolitan Opera House. The young folks get the dance music from an orchestra conducted by a Vincent Lopez or a Paul Whiteman located somewhere in the Big City. The old fellows who refuse to leave their business at home stand around a horn from which pours an endless string of stock quotations and market reports. Others listen to lectures on their favorite subjects.

After passing the half-way mark on the ocean, things begin to pour in from the continent. The Europeans are wide awake regarding the possibilities of the radiophone as an instrument for the dissemination of propaganda. Politics fly everywhere. Oh, what a conglomeration of jargon—English, French, German, Spanish, Russian, Greek, Italian—all trying to impress their views on the newcomers. The French conduct one commendable policy—that of offering a short speaking course in their language, for the benefit of tourists. It sounds queer to go into a room and hear a large group of people repeating, over and over, and each in his own way, "comment allez vous" "tres bien, mercie," and "Oui, monsieur," according to the instructions coming from the mouth of a tin horn.

Landing at Cherbourg, we take the first train to Paris. The trains now are not the slow, stuffy affairs of the past, but attain a truly creditable speed due to their electric motors supplied by radio power, and the air is kept in circulation by electric fans supplied from the same source.

During our stay at the French capital we have occasion to use our pocket receiving sets; and while walking the streets we can pick up time signals, announcements of the various features of current interest in the city and other reports, all being broadcast from the Eiffel Tower.

In most of the towns on the continent we notice a marked progress. This is chiefly due to the success of wireless power transmission. Electricity is found in the small hotels, and even in some of the peasants' quarters, with its accompanying light, heated rooms and warm water.

We leave Europe for a little sight-seeing trip to Egypt. Even at Gizeh, in the shadow of the pyramids, a spot representative of silence and mystery, we are still sitting on the door-step of the world. While an aged muezzin in a towering minaret in Cairo calls the followers of his faith to prayer, we listen to the strains of a violin in the hands of a master of the period, being hurled to the extremities of space.

After a delightful trip down the Nile, we arrive at Khartoum; only to find to our dismay that we had miscalculated the expenses of the journey and are without money. A radiogram from Cairo extends our credit.

We learn that a trip down through the center of Africa, from Alexandria to Cape Town, is now perfectly safe. Radio "land-marks" have been set up at determined distances, and by the aid of a small receiving set, it is almost impossible for an explorer to get lost. However, we reserve that trip for another time, and start on our way for Suez.

The trip across the Syrian desert is no longer shrouded with terror, for the bandits are rather shy of the wirelessly equipped military airplanes that may be summoned on very short notice. So, light of heart, we take this route over to Bagdad.

Despite some modernizations, the city of the Arabian Nights has lost but little of its charm. However, the great arm of radio is in evidence. By its aid, modern entertainment is obtainable at numerous places. At one time, when listening in on our pocket receiver, we are astounded to hear a disciple of the Prophet calling the familiar "There is no God but Allah."

Proceeding on our journey we reach Bombay and go inland through the Indian jungle. One day we become separated from our guides and are apparently lost. Our pocket receivers again prove of value, for upon listening we hear the party sending instructions that will guide us to safety.

At Darjeeling we learn from returning travelers that Everest has been conquered—with the assistance of radio. Exploring and mountain climbing parties had kept in touch with each other by means of these all-pervading ether waves, and had worn electrically heated suits receiving their energy from radio power.

In China, by the messages flying through space, we learn that the nations of the world are disputing their rights to each other's claims in this country. In one province we are held, pending the radio visa of one of the consuls. The government weather reports are very useful, as the conditions at the present time are uncertain.

For several days after leaving the Hawaiian Islands the air continues to vibrate with the strumming of the ukeleles and guitars of those balmy isles.

Our ship is guided into the port of San Francisco by waves emanating from a submerged cable. Someone is taken very sick, before the boat docks, and the attention of a specialist is at once secured via radio.

After once more putting our foot on native soil we proceed by radio-controlled conductorless train to our home city, our friends learning of our arrival by radio, before the train has completed its journey.

Once more in New York, we sit down and ponder. We have travelled around the world, but our home and friends were always with us. We are now at home, but, thanks to radio, the world is at our door.

Safety in the Use of Terminal Blocks

By Arthur S. Gordon

WHENEVER a panel is in danger of being overcrowded, the thing to do is to shift the battery terminals around to the rear of the receiver. This is done by employing a small strip of hard rubber or other insulating material drilled so as to take the number of binding posts necessary, which is usually four in the case of a single tube receiver and five in the case of multitube outfits. This strip is known as a "battery terminal block" and is generally screwed on the rear edge of the baseboard, either in an upright or horizontal position. It is usually upright when the instruments are not to be enclosed in a cabinet, and horizontal when they are to be so enclosed. Fig. 1 shows the two applications of the terminal block idea, A and B, the latter sketch also indicating the manner in which a cabinet may be built over the block.

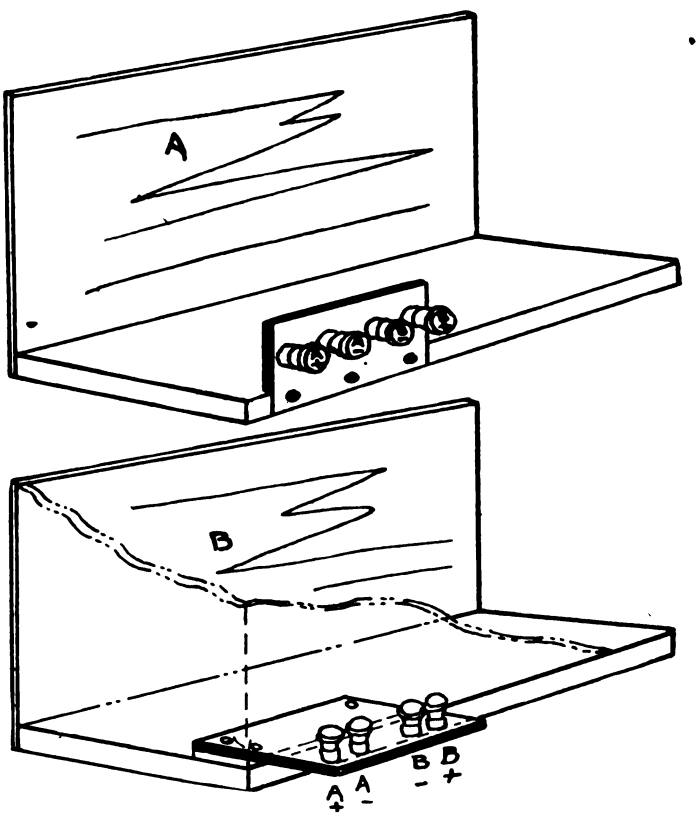

Fig. 1—Two methods of using a terminal battery block on your panel. It simplifies connections and keeps unsightly wires and connectors from the front of the panel.

The advantages of having the battery connections go to a terminal block in this manner are many. Not only is the panel simplified, but the task of wiring the set is made much easier. The leads are shorter, for one thing, and for another the grand mixup of wires rushing to eight terminals on the face of the panel is somewhat cleared out. This shortening and separating of leads makes for greater efficiency. Moreover, the appearance of the receiver is enhanced because the battery leads approach the set from the rear, instead of from the front. Because of these points the use of the terminal block is especially recommended for amplifier units, where there is a limited panel space and where there is need for a device of this sort to lessen the chance of a wrong connection.

While on this subject of A and B battery connections, some radio enthusiasts may have noticed with surprise that some of their more advanced radio friends use three binding posts instead of four. Most hookups call for four binding posts, and the majority of sets use them, but as a matter of fact, only three are necessary. (See the single circuit regenerative hookup, Fig. 2) *The extra binding post, while not needed at all, is added to minimize the chance of burning out your tube by wrongly connecting the B battery terminals to the A battery binding posts.* In the case of only three binding posts, this can be done very easily by merely touching the A+terminal with the B+lead, provided, of course, that the rheostat is turned on. Amateurs who disregard the safety check afforded by the fourth binding post do so at a risk that most of us do not care to take.

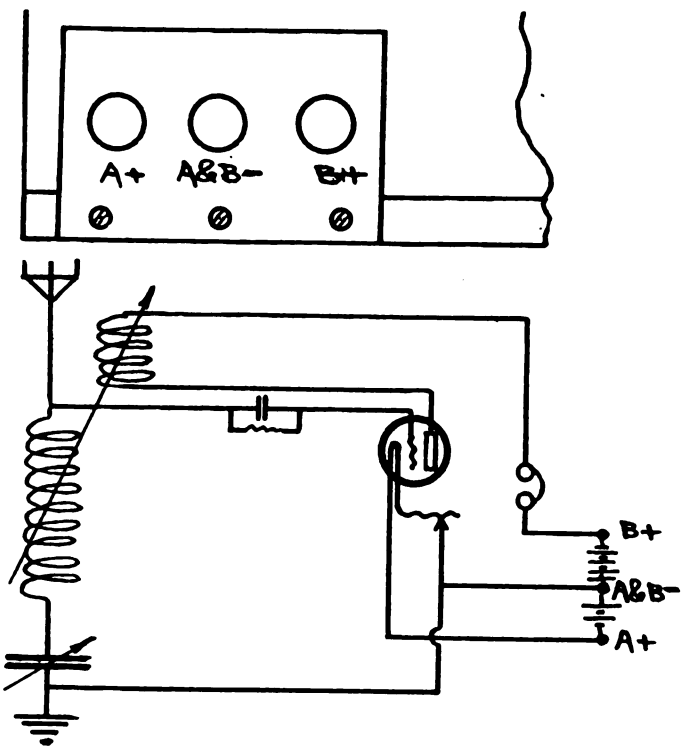

Fig. 2—Suggested method of using the terminal block. Note that one binding post serves for both the A and B minus.

Watch Out!

MANY constructors intend using the new U. V. 199 tubes but do not take into consideration that a six ohm rheostat will not efficiently operate these tubes. The resistance should be 30 ohms —not 6, and care should be taken that not over three dry cells in series are used.

A Little Now and Then

DO not forget to occasionally oil the moving parts of your set. Shafts of the rheostats, couplers, variometers and condensers need oil, and a drop of light machine oil sometimes adds to the ease of working these parts and keeps them in good working order.

RADIO PRIMER

For the New Army of Radio Beginners

By Lynn Brooks

SOLDERED CONNECTIONS: In radio circuits all connectors should have as low resistance as possible. Therefore large sized wire is used in connecting and all connections are soldered. You not only assure yourself of low resistance joints where this is done, but you prevent any of the connections working loose or corroding.

Few people know how to solder correctly, and while it is an art in itself it is simple if it is once understood. In order to correctly work with a soldering iron, certain apparatus is necessary. The first is a well tinned soldering copper. For radio work this should be a light iron, as it is often necessary to get in small corners, and the regulation tinner's iron is incapable of doing this. Therefore if you cannot obtain an electric soldering iron, of the kind specially made for radio work provide yourself with a four ounce copper one.

The next important accessory to a successful soldered job is a good non-corrosive flux. Do not make the mistake of using an acid base flux, for if you do, it will corrode the copper wire and cause you no end of trouble. About the best flux for radio work is a resin base flux, with powdered resin as a close second choice. As the iron will have to be tinned before it will flow solder properly into a joint, it is next necessary to tin the iron. Place some of the flux, or resin on a tin plate. Heat the copper until it begins to show green flames around the edge. Do not make the mistake of burning the iron by letting it get red hot. When it is sufficiently hot take a piece of solder (wire solder is best as it is easier to work with) and rubbing the iron gently in the flux, melt the solder and rub the iron around in it until the solder coats the surface. When all four sides of the tip of the iron have a nice coating of solder you are ready to solder any joint.

Before soldering a connection, see that all the surfaces are clean and free from any grease or dirt. It is best to scrape the surface of each piece with emery paper to make sure. Then apply a light coat of the flux. Do not use much, but just enough to allow the solder to flow freely. If too much is used it will spread and cause a dirty looking connection and dust and dirt will stick to it. Have the soldering iron hot (*not red hot*) and apply the tip of it to the joint, to allow the parts to get warm. Then still holding the iron to the joint, apply the solder. When a small amount of solder has melted and run to the joint, remove the solder and leave the iron there a few seconds until the solder runs into every crevice and a nice smooth joint is made. If the iron is not hot enough this will not happen, and a dirty lumpy joint will be the result, but never let the iron get so hot that it burns the tinned surface off.

The iron should frequently be scraped with the emery paper and retinned. A connection should never be attempted unless the surface of the iron is bright and shiny with a good coating of solder.

SOLDERING OUTSIDE WIRES: Where work has to be done in the open, such as soldering the outside wires of an antenna, it is best to use a gas torch and a special paste. Because of the fact that copper dissipates heat quickly, a soldering iron will not hold the heat long enough to properly solder it. Therefore make up a paste of your regular soldering paste and pour plenty of finely filed solder into it. Mix enough of this to make a thick lumpy material, and when ready, place it all around the connection and apply the heat of the torch until it melts and flows into the joint.

Amateur Gets First News from Arctic Ship

HARTFORD, Conn.—Old IZE, the amateur radio station operated by I. Vermilya of New Bedford, Mass., who is claimed to be the first transmitting amateur in the United States, was the first to receive an authentic press report from the MacMillan Arctic expedition after the schooner "Bowdoin's" departure from the Maine coast.

The previous day a personal message was sent by Donald H. Mix, radio operator on the schooner, to Mr. Vermilya, who is manager of the New England Division of the American Radio Relay League. This radiograph, telling how the New Bedford station's signals were received, read:

"We are now in Boothbay and expect to leave for Sidney. Your signals very strong, will reach Pole easy. The MacMillan Arctic ship spent the day preparing for sea, adjusting compass, lashing deck cargo, etc. Captain MacMillan expects to put out to open sea."

The first message from WNP received by any amateur station was picked up by 1CKP, at South Manchester, Conn., owned by George H. Pinney of that place and operated by Charles A. Service, assistant secretary of the A. R. R. L. Mr. Pinney was thanked for a gift of silverware.

These are two of the most powerful amateur stations in New England and both owners expect to maintain constant communication with WNP. Mr. Vermilya is so anxious to have his transmitter reach the "Bowdoin" that he has sought permission of the management of the New Bedford hotel to erect a "super-antenna" on the roof of the building.

He maintains an experimental license, IXAL, which enables him to operate with extra high power. His station will be equipped eventually with four 250 high tubes, giving it a total power of 1,000 watts. With this outfit he believes it is an easy jump from New Bedford to the North Pole.

RADIOGRAMS

WORLD NEWS HAPPENINGS BRIEFLY PHRASED FOR OUR BUSY READERS

Major General James G. Harbord, president of the Radio Corporation of America, sailed for France last week on the "Paris."

* * *

The maximum daily light requirement of an average American home is 460 candles, or eighteen times that of a century ago, and the cost is only two-thirds of what it was then.—*Floyd W. Parsons.*

* * *

Increases in wages of deck and engineer officers, radio operators and members of the stewards' department on Shipping Board vessels ranging from $7 to $20 a month are announced by Vice-Chairman T. V. O'Connor of the board. The increases are effective immediately.

* * *

Every up-to-date ship in the bootlegging fleet in "rum row," off the New Jersey and Long Island shores, is said to be equipped with a wireless set, which is used for both entertainment and business purposes.

* * *

The recent radio fair held in Mexico City aroused considerable interest, and there has been an increase in sales of radio telephone apparatus. Some low-priced German equipment is now coming on the market, the Department of Commerce has been advised.

* * *

David Sarnoff, vice-president and general manager of the Radio Corporation of America, is famous as the man who, eleven years ago, received in New York, from the S.S. "Olympic," 1,400 miles at sea, the message confirming the sinking of the S.S. "Titanic."

* * *

The Shipping Board receiving station at London reports that, for the past two years, they have had much heavier static in winter than in summer, and that, although heavy static has been experienced during the past winter, receiving conditions have now greatly improved.

* * *

Radio and the phonograph are not really competitors, but complement each other in the public's purchasing mind, according to a phonograph sales manager. He claims that neither is a substitute for the other as far as public or household entertainment is concerned. In the case of a prominent after-dinner speaker the phonograph will not enable the public to hear him, but radio will. If a musical composition by a favorite performer is desired at a specific time the phonograph record is ready to reproduce it. The sales manager says his company is erecting a new record-making building, which he hopes will enable him to catch up with his demands.

Radio communication between Singapore and Christmas Island was established recently, a report to the State Department advises.

* * *

During a single day, May 25, 1923, the Navy Department Communication Office handled a total of 858 messages. This was the "high mark" in two years' service.

* * *

The United States has in nightly service nearly twice as many electric lights as the people of the next seven most important countries combined, according to the New York State Committee on Public Utility Information.

* * *

Henry A. Stone, of Roselle Park, N. J., since 1909 chief electrician of the New York Stock Exchange, died last week in the Bonnie Burn Sanitarium at Scotch Plains, N. J., aged 57. He was one of Edison's early electrical lieutenants.

* * *

Arthur T. Nelson, commissioner of the Missouri Board of Agriculture, informs RADIO WORLD that Station WOS, owned by the state of Missouri and operated by the State Marketing Bureau, Jefferson City, Mo., has changed its wave length from 360 to 441 meters, or 680 kilocycles. The station's slogan is "Watch Our State."

* * *

Leonard E. Curtis died at his home at Colorado Springs, Colo., last week at the age of 75. He was born at Norwalk, Ohio; was graduated at Yale College and practiced law in New York City till 1896, when he removed to Colorado. He was distinguished as an electrician. He was author of a volume of world-wide travel and reminiscences of Edison, the Maxims, Westinghouses, Tesla, and other electrical notables.

* * *

James H. McGraw, president of the McGraw-Hill Company, publishers of New York City, has presented to Princeton University a valuable library of 3,000 volumes on the French Revolution. The books were assembled by the late William D. Weaver, of Charlottesville, Va., a naval and electrical engineer who was for many years editor of the *Electrical World.* In making the donation Mr. McGraw said that he was prompted by his high regard for Mr. Weaver and "to show my appreciation of what Princeton University has done for the higher education of young men of our time, including three of my own sons."

General Gouraud Addresses America Over Radio

(C. Photonews)
General Gouraud, the one-armed hero of France, who recently spoke to the radio audience through Station WJY, from the 69th Regiment Armory, New York City, where he reviewed the veterans of the Rainbow Division. As the General does not speak English, it was necessary for his aide-de-camp to translate the speech. The General was amazed at the enormous strides we have taken in radio, and was duly impressed when told that hundreds of thousands of unseen but intent listeners were hearing his praise of the American troops that were under his command during the war.

Radio Public Hears President Harding's St. Louis Speech

(C. Underwood and Underwood)
Last week the entire country was enabled to be a part of the vast audience that heard President Harding speak from the St. Louis Post Dispatch Radio Station KSD. Whereas you formerly had to wait for the papers and despatches in order to keep in touch with the activities of the President, you now can be right at his elbow by means of your radio set. Never before has the President been able to keep in such personal contact with the people of this nation as since the advent of radio. The illustration shows President Harding standing beside the two microphones that picked up his every word that it might be heard in the four corners of the United States.

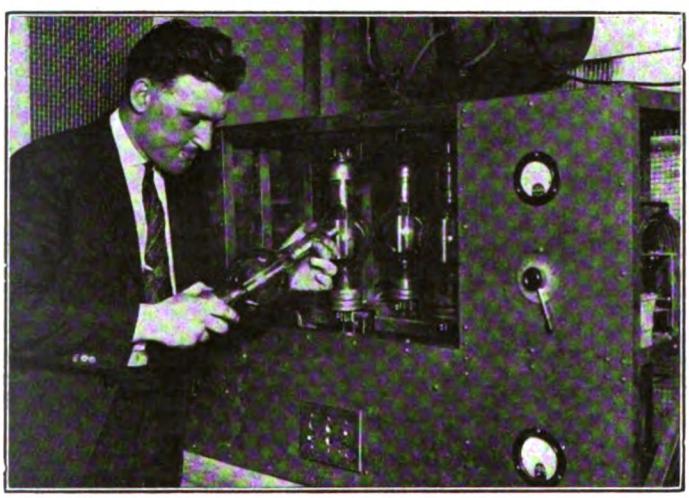
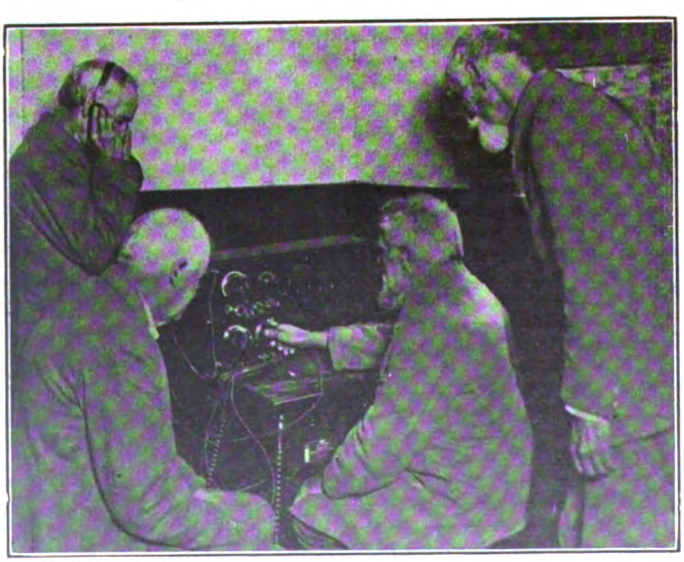
(C. Kadel and Herbert)

There are two ways of taking golf lessons, it would seem. One is by quite expensive instruction and the other method is by radio. The illustration shows three fair exponents of the game learning the gentle art of putting by means of a local broadcasting station and professional golfer, who is giving instructions via the ether waves. Wonder if instructions are necessary as to what to say when you muff one?



(C. Kadel and Herbert)

Many broadcast listeners will remember old Station WDT, the broadcast station of the Ship Owners' Radio Service. The illustration shows the new transmitter that is being used since the station has reopened and is operating on its new wave length. With the new equipment, this station radiates over ten amperes and is expected to establish some new distance records.



(C. Acme Service)

It was a great day for these grizzled Confederate Veterans when they were able to hear the decoration day servics that were broadcast over Station WSB, the Atlanta "Journal's" broadcasting station. These old war horses were given a brand new radio set and shown how to operate it, and the first program that they tuned in was the reunion services from that famous Southern station.

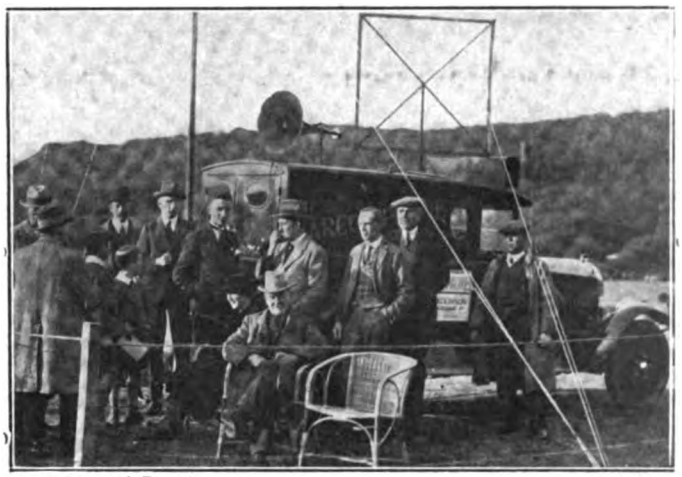
stations that it was considered impossible for fans on the east coast to hear.

As every contest nowadays seems to run along the lines of endurance, it is not impossible for this record to be beat if you possess the "stick-to-it-iveness" necessary, but you must not record a station more than once, and even at that you will have to go some to beat the record of these feminine enthusiasts.

Now, Radio Golf Hounds, come on in and see if you can't give these girls a run for their money. Let some of you that have been asking about super-regenerative and six-tube radio-frequency amplifiers see if you can't make them step. It sounds pretty hard, but if they could do it, you can, too; so go to it and "let 'er rip."

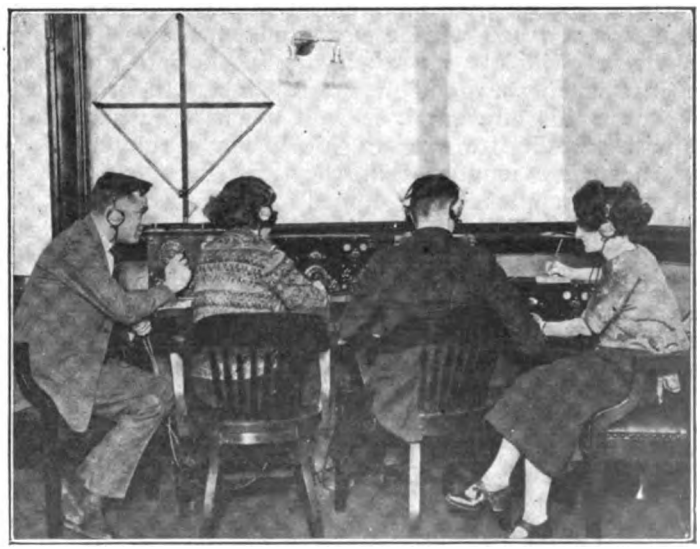


(C. Topical Press)

In order to popularize radio in England, the Marconi Company of Great Britain has equipped several motor cars with broadcasting equipment and is touring the countryside showing the people how easy it is to receive broadcast programs. The photograph shows one of the cars located at Peasholm Park, Scarboro, England, with an interested audience listening to the program on a loop receiver.

(C. Kadel and Herbert)

Mme. Marguerite Namara, American opera star, and her six-year-old daughter, who are touring France in a motor bungalow, listening to a radio program while traveling in their luxurious motor car. A loop antenna is used with a set using radio-frequency amplification and wonderful results are possible with this type of apparatus. Radio equipment is only one of the modern luxuries of this wonderful traveling home, which is as fully equipped as any modern bungalow.



(C. Kadel and Herbert)

The Federal Telephone and Telegraph Company staged a novel radio golf contest between employees of their several offices. Using the various types of sets that the company makes the employees set about to get the most stations. The contest was limited to one hour, and the winner was J. B. Ritchey, 90 Alexander Square, Newark, N. J., who won by copying 28 stations with a total mileage of 3,800 miles. Mr. Ritchey, the winner, is the man with the dark suit.

Paris Has Boulevard Radio Concerts

By Carl H. Butman

THE well-known Parisian daily, *Le Matin*, is operating a concert radio receiving set in front of its office on a popular boulevard, where crowds gather to listen to news, concerts and statistics from fourteen amplifying horns. The amplifiers are sufficiently loud to be heard over the terrific traffic noises, Consul Ives reports from Paris.

The public listening-in station was installed by the Societé Francais Radio Electrique which broadcasts two concerts daily on 1,780 meters. Other broadcasting is done by the Eiffel Tower on 2,600 meters, and the Superior School of the Telegraph and Telephone Service of the Government on 450 meters.

No provision for a royalty to broadcasters has been made in France, beyond the payment of an annual fee of ten francs to the French Postal Service by owners of wireless receiving sets. The Eiffel Tower radiations are sent out for the general public, and the Superior School broadcasts are carried on in the interest of education and experimentation. The Societé Francais Radio Electrique, however, states that it obtains its remuneration by the sale of the Radiola receiving sets adapted to the broadcasting system used by the Societé, explaining that in order to receive its wireless concerts properly it is essential that a Radiola set be used. The assertions of the company are borne out by private set owners who say that other receiving sets are unsuitable for the company's broadcasts, concerts being heard very indistinctly with other sets if at all.

Listening-in is becoming popular in France, it is reported, although not as extensively as in the United States. Anyone may own a receiving set there, but transmitting outfits must be licensed by the Government. French receiving sets are advertised for sale as low as 250 francs each. No specific import duties are prescribed for complete radio receiving sets, but the different parts are dutiable separately.

Most of the French broadcasts are on long wave lengths, except those of the Superior School. It was learned recently, however, that the French military authorities are experimenting in broadcasting on the 45 meter wave.

Summer Tips to Summer Fans—No. II

By R. L. Dougherty

Another little point that will cause no end of trouble to the inexperienced fan who is radiovacationing is the dew. This is not meant as a pun or joke. A heavy fall of dew in the evening can practically ruin the receiving range of a receiver. The dampness will soak through the set and form numerous little short circuits. It will collect on the panel, between the switch points, on the coils of the rheostat, around the grid leak, and in fact every place that it is possible. Make sure when you take the set away with you that you have ample facilities to keep it dry. A good heavy cover the inside edge of which is lined with felt or rubber will suffice—if the cover is clamped on when the set is not in use. The dew will also spread over the insulators and coat them with a goodly layer of moisture which will short the insulator and you will be surprised when you find that your set will lose its sensitivity in the late evenings, just when the good programs start. In order to overcome this bugbear it is well to coat the insulators with paraffine, or even to shield them if they are strung in such a manner that they can be shielded. Good heavy wrapping paper dipped in oil or paraffine, formed into a tent-like shape and hung over the insulator will keep the insulator dry and serviceable, even through a heavy rain. When shielding it do not make the mistake of using something for a shield that will short the antenna itself. Tin or metal should not be used. Don't run your antenna through leafy trees or foliage.

As a hint to fans who take away crystal sets it will be well to caution them to carry plenty of spare crystals that have been tested for sensitivity, as well as an extra set of catwhiskers. While on the matter of crystal sets it would be well to tell the crystal fan to lightly oil all moving parts, such as sliders, with a good watch oil or sewing machine oil. Don't bathe the parts with it, but just use enough to keep them lightly lubricated and keep them from corroding or rusting.

One of the important details in a set is cleanliness, and this should not be neglected in the set that you take on your vacation. Dust will collect easier on a portable set in the country than on one that is left on the table and constantly cleaned. Do not let dust collect between switch points, binding posts or any other place. A light brushing every morning or evening with a fine brush will keep your set clean and you will not be hunting for trouble.

Finally, as an added caution if you intend taking a tube set with you it will be well to provide some method of keeping the tube safe. A box lined with cotton, and the tube carefully placed in this is the safest method, unless you desire to "chaw up the atmosphere" after a hike or ride when you find that your tube is "gone galley west." In line with this, it would also be well to incorporate an extra dry cell and small B battery as reserve supplies. Strange things happen to batteries in different climates, and in places like the seashore or mountains when it is extremely warm or hot in the day and cool in the evening you are liable to find your batteries die on you very quickly, or else they will get lumpy and "start shootin'" out of the cover. If you have an extra on hand which you have kept dry you will not have to miss an evening's fun just because you have to send to the city or the nearest town for a new one.

Newsdealers, Attention!

Many newsdealers have found that there is a constant demand for back numbers of RADIO WORLD. If you have a copy or two of current issues over from week to week, keep them in stock and you will find that your customers will want them.

Back numbers of RADIO WORLD contain a wealth of information for everybody interested in radio.

Ringing Over Multiplex Transmission Channels

No. 1,454,150: Patented May 8, 1923. Patentee: L. Espenschied, Queens, N. Y.

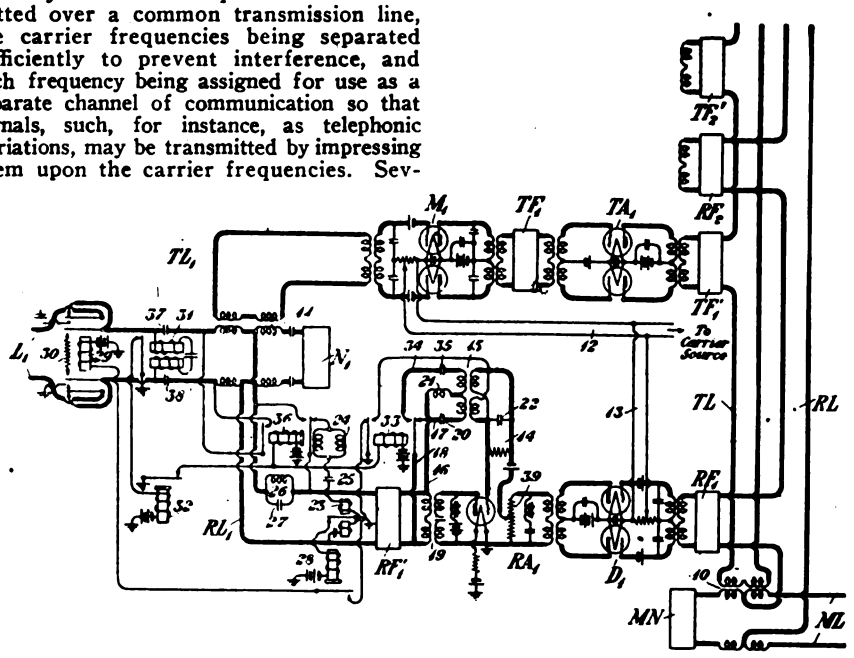
This invention relates to transmission systems and more particularly to multiplex transmission systems employing carrier currents. The present application is a continuation as to common subject matter of applicant's prior application, Serial No. 314,074, filed July 29, 1919.

Where multiplex transmission is attained by the use of carrier currents a plurality of carrier frequencies are transmitted over a common transmission line, the carrier frequencies being separated sufficiently to prevent interference, and each frequency being assigned for use as a separate channel of communication so that signals, such, for instance, as telephonic variations, may be transmitted by impressing them upon the carrier frequencies. Several channels may thus be superposed upon a common transmission line and each channel performs the functions of an ordinary telephone transmission line.

In ordinary telephone transmission it is customary to transmit over the line, in addition to the telephone currents, ringing currents or other signaling currents, for the purpose of signaling between operators in establishing connections. In order to obtain practical telephone service over each carrier communication channel, it is desirable that the channel be utilized for the transmission of such ringing or other signaling currents as well as for the transmission of ordinary telephone currents.

This invention, therefore, concerns means whereby ringing and other signals may be transmitted for each carrier channel.

The invention likewise has reference to the provision of a transmission system having included therein a vacuum tube which normally acts to produce one desired result, but which under other conditions, operates as a generator of oscillations.



Espenschied's method of duplex telephone transmission.

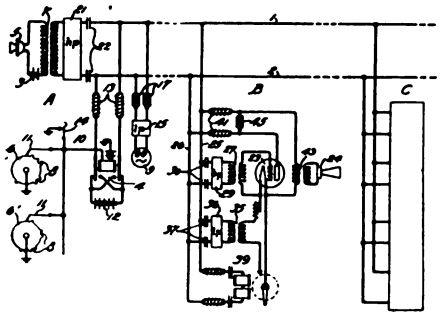
Energization and Control of Vacuum Tubes

No. 1,456,528: Patented May 29, 1923. Patentee: Herbert E. Shreeve, Wyoming, N. J.

THIS invention relates to the control and energization of vacuum tube amplifiers, and aims to economically effect such control and energization from a distance.

Any or all of the quantities (*a*) input electro-motive force for the tubes, (*b*) plate current, and (*c*) filament current, may be supplied from a point remote from the tubes over a wire system being simultaneously used for intelligence communication purposes; and the amplifiers may, if desired, be selectively rendered operative and inoperative by means of impulse selectors or the like controlled over the same wire system.

The invention is especially useful in selective signaling systems, such, for instance, as train despatching systems employing loudspeakers at various stations along the right of way, and is disclosed hereinafter with particular reference to such systems. However, the invention obviously may be employed in connection with other systems where distant control or energization of vacuum tubes is desirable without departing from the spirit of the invention or the scope of the appended claims.



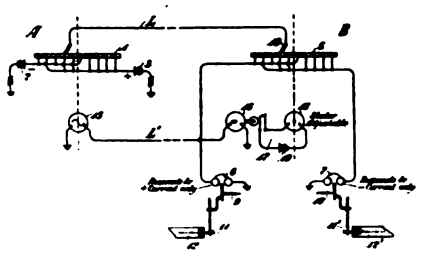
Method whereby filament and plate current can be transmitted from a distant source.

With a large number of stations distributed over a long railway line, to supply batteries at the stations for energizing the amplifiers would be unduly expensive, especially since there are ordinarily no battery charging plants at the stations. According to this invention the undue expense is obviated by supplying energy to a number of such tubes from a distance, and using the signaling wires along the right of way to transmit this energy. Further, in accordance with the invention, the operation of the tubes is controlled from a distance by selectively controlling the filament current of the tubes, for instance, and the signaling wires along the right of way are employed for effecting this control.

System for Measuring Distortion

No. 1,455,843: Patented May 22, 1923. Patentee: Maclean Kirkwood, East Orange, N. J.

THIS invention relates to telegraph systems and more particularly to the measurement of the distortion in telegraph signals due to the transmission over the line. Heretofore it has been customary to judge the quality of telegraph signals by ear, an expert operator being able to distinguish between good and "clippy" or "heavy" signals; but the results of such tests are uncertain and unsatisfactory. It has also been proposed to make a record of the undistorted signal as sent out and a record of the distorted signal as received and to compute the distortion by comparing the lengths of corresponding spacing or marking impulses. It is the object of the present invention to provide means for indicating directly the distortion itself.

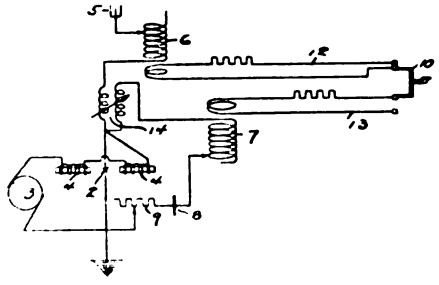


System by which it is possible to visibly measure distortion in telephone and radio signals.

Radiotelegraphy

No. 1,454,630: Patented May 8, 1923. Patentee: H. F. Elliott, Palo Alto, Cal.

The invention relates to radio telegraphy signalling systems and particularly to single wave signalling systems, in which the source of oscillations is connected to the antenna circuit and to a local oscillating circuit, the electrical constants of the two circuits being such that the oscillations may be caused to prefer one circuit to the practical neglect of the other. Systems of this nature are particularly advantageous in continuous undamped wave signalling, in which the source of oscillations is an arc or other continuous undamped wave generator.



New system for the control of local oscillations.

Answers to Readers of Radio World

Can Erla radio-frequency transformers be used in a two-tube reflex circuit in conjunction with Jefferson audio-frequency transformers? My set uses these transformers, and I get nothing but loud beat notes and squeals. Can the use of definite transformers cause this?—Jules F. Lavalette, Box 287, Lenox, Mass.

These transformers (both audio and radio) can successfully be used in reflex circuits. Be sure that you have the right connections, and that your transformers do not interfere with one another. A method of preventing this interstage coupling is to separate them a sufficient distance and, if possible, shield them by means of foil or screening. In the audio-frequency transformers it is sometimes helpful to ground the cores of each transformer to the ground post, but extreme care should be taken first in finding out whether the cores of the transformers are not used to make one of the connections. Go over your connections very carefuliy and make sure of all of them. In reflex circuit construction it is best to solder each connection.

* * *

Will the circuit shown in the January 20 issue by Arthur Gordon work a loud-speaker? Can a Flewelling circuit be made with two steps of audio-frequency amplification, and where can I obtain the circuit diagram for the additional two steps? I have been thinking of trying the G. W. May circuit, in the February 17 issue. Can that circuit be accommodated to a loud-speaker? —G. W. Archer, Tabernash, Colo.

If you add two steps, or one step and a power amplifier, to these circuits they will all operate a loud-speaker. A suitable two-stage audio-frequency diagram for all of them appeared in RADIO WORLD for March 31 in answer to a question similar to yours. If the circuit is to be used with anything but a Flewelling it will be necessary to remove the grid leak that is hooked across the primary of the first transformer. If you desire to construct a power amplifier we refer you to RADIO WORLD for June 9, where you will find a suitable description and diagram by C. White, consulting engineer. This power amplifier, in conjunction with one stage of straight amplification, will allow tremendous amplification, and will suit your needs.

* * *

In the use of a loop antenna, is it possible to tune out two stations when they are both on the same wave length? Will a loop antenna work on a crystal detector and one stage of audio-frequency amplification?—C. J. Dickenson, West New York, N. J.

When two stations are on exactly the same wave length it is not possible to tune either one out and get the other without interference. It is generally the case that, if the set is detuned a bit, or the loop turned at right angles and the set manipulated correctly, the stronger station will be heard the clearest; but the elimination of the other station entirely is impossible. It is not advisable to use a loop antenna on a crystal set as the results are so poor that it is just wasted energy in putting it up.

* * *

Kindly inform me where the transformer T2 shown in RADIO WORLD for Feb. 27, in connection with the power amplifier of C. White, may be purchased.—E. K. Seibel, 317 Broadway, Hannibal, Mo.

Address a letter to the writer of the article, care of RADIO WORLD and re-state your question.

I have constructed a three circuit Armstrong regenerative set with two steps of audio-frequency amplification. I am continually bothered with a squeal. The apparatus is laid out as shown in the accompanying sketch. I do not have to throw the antenna switch to get the squeal started, as all that is necessary is to turn on the tubes. The detector and one step works quite well, but I cannot get any results out of the second stage.—Donald Edwards, Box 12, Callicoon, New York.

From your description and the sketch it is very easily seen that your transformers are entirely too close. There should be quite a bit of space between the first and second stage transformers and they should be placed at right angles. You state that you placed them close to save space. This is wrong. Suggest that you separate them at least six inches and place them at right angles. The trouble you are experiencing is due to magnetic coupling between the transformers. The trouble you notice when you place your plate variometer at zero is due to the fact that the set is oscillating. This will cause a howl because the set is tuned wrong. Re-wire your amplifying circuits and run your leads so that those of the first and second stages do not interfere, or run parallel for any distance. If possible it is good practice to ground the core of the second stage. When doing this, be careful that the metallic part of the core is not used as a connector for some part of the winding.

* * *

Kindly explain how I can use the outside light wires as antenna. I notice that the Flewelling published in RADIO WORLD *is different from one that I saw in another publication. Yours uses three condensers and the other one called the "Flivver" used but one. Which is the best?—Geo. Read, 1224Plainfield Ave., Grand Rapids, Mich.*

It is never advisable to use outdoor light wires as antenna. Where lighting wires are strung on poles, it is always best to leave them alone. They may be high tension and serious injury if not death will ensue if they are tampered with. Run your antenna away from them and take care that your antenna does not cross them. The circuit you mention is an adaptation of the original Flewelling as published in RADIO WORLD. It has been found that the circuit will function without the bank of three condensers, although not as much volume will be produced.

* * *

Would the U. V. 201A tubes work as efficiently as the U. V. 199 in the Grimes inverse duplex circuit? Where can I get a blue print of this set in order to enable me to build it?—F. H. Gripp, Penokee, Kan.

These tubes will work in the circuit you mention. We do not carry blue prints of circuits or panel layouts. You do not need blue prints to build this set. Follow the diagram and plan your own panel layout. Care should be taken, however, to see that it is done correctly or the good results possible with this circuit will not be obtained. Follow the diagram exactly.

* * *

I would like to know if I need a permit to operate the combined receiver and transmitter as shown in the accompanying sketch.—Jos. Rossi, 302 West 55th St., New York City.

A license is required for any transmitting station and you will have to obtain a license before you can operate such a set.

Will a WD-11 tube operate on a loop antenna in a house? Will it operate on a light socket antenna? Would there be any advantage gained in the use of both of them together? Kindly inform me of a good audio-frequency transformer to cost around $5.00. What size and how much wire should wind on a good home-made loop?—A Constant Reader, 242 Mountain St., Montreal, Canada.

With a properly designed circuit it is possible to get a WD-11 tube to work on either a light socket antenna or a loop. A single tube reflex circuit with crystal detector is best adapted for this purpose. There would not be any decided advantage gained in the use of both together. See our advertising columns. There are several advertised. We cannot give the name of any make of competitive apparatus through this column. For the construction of a homemade loop about 10 turns of either stranded light cable, or No. 18 wire on a three-foot square frame will do for broadcast work.

* * *

Can I construct the power amplifier described by C. White in RADIO WORLD *for June 9, by the use of regular audio-frequency transformers hooked up as per sketch? If possible should I use the ratio as shown in the sketch? (Two low ratio and two high ratio). Can a Ford ignition coil be used for the purpose?—Edward H. Bitner, 1510 Catherine St., Harrisburg, Pa.*

It is impossible for you to use transformers for such a purpose as you suggest. The transformer which has to be used is a special transformer made especially for that purpose, and the use of any other type will not be satisfactory. If you attempt to use two transformers hooked in series as shown you will generate a double frequency which will cause terrible howling, as the two transformers will virtually buck each other.

* * *

I have the three circuit regenerative set as shown by the enclosed diagram. I cannot get any distance out of it, and it does not give me very good volume. The furthest station that I have received as yet is KDKA, and I have a hard time getting that. What can I do to improve my set? —Leslie Baverstock, 654 Humboldt St., Brooklyn, New York.

The three circuit regenerative set is somewhat tricky to manipulate and it is best to get thoroughly acquainted with it before trying for distance. You might put a 23 plate condenser in your secondary circuit which will help your selectivity somewhat. Outside of that there is nothing that can be done but getting used to the control and tuning of it. Make sure of your connections, and see that they do not run too far parallel, and that they cross at right angles.

* * *

I recently purchased a set incorporating what was said to be a "German Mercury" tube. After about a week of use the tube did not work, although it lights very bright. Can anything be done to restore the sensitivity of the tube?—Carl Spangerberger, Woodstock Manor, Kansas City, Mo.

We have no knowledge of the tube you mention. If it is a make of tube imported, we advise you to get in touch with the party who sold it to you and make your report. There is no reason for a tube to stop rectifying as long as the tube lights up, unless you have injured the plate or grid by rough usage.

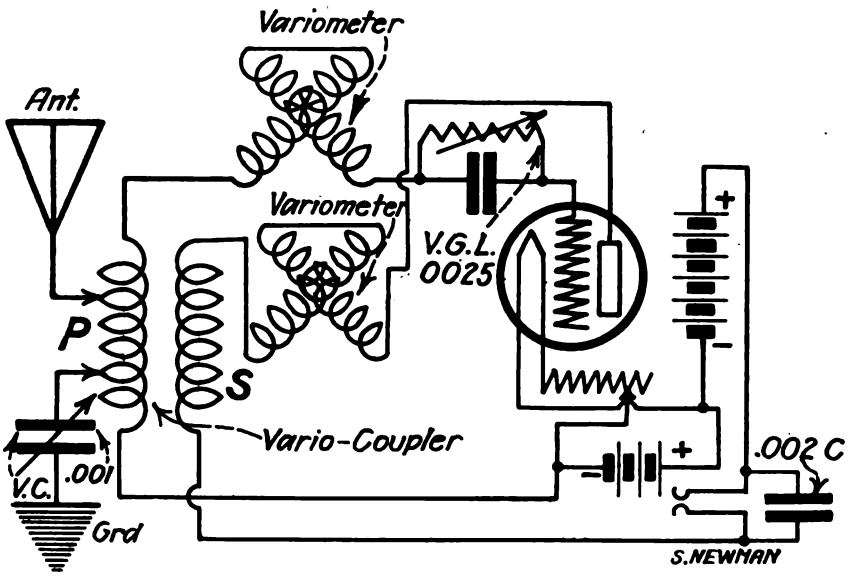
An Extremely Selective Single Circuit One Tube Set

By A. Clapholtz

SINCE the allocation of new wave lengths in broadcasting, the interference between different stations has been almost entirely eliminated. At the same time there are a lot of single circuit receivers that are still bothered with interference. Owning one myself, and being able to hear the powerful broadcaster WEAF over the whole range of my coupler on account of the fact that I live but a half mile from that station, and desiring to tune him out, I tried to develop a single circuit regenerative tuner that would enable me to get DX and at the same time hold the volume of the original circuit.

With this point in mind I thought of combining the three circuit and the single circuit, using the selectivity of the triple circuit and the volume of the single circuit. I finally hit on the circuit described, and if a fan wants real selectivity and volume on one tube, the added expense of rebuilding his single circuit will be amply repaid the first time he turns on his tube and tunes in. For selectivity it can't be beat.



Extremely selective circuit as described by A. Clapholtz.

The only changes that will have to be made in any single circuit receiver that uses the rotor of a coupler as a tickler, will be to add two variometers, one in the grid circuit and one in the plate circuit.

The only change that will be noticed is the manner in which the set will be tuned. In tuning in a station with this new variometer single circuit, both variometers are placed at 100, and the rotor of the coupler turned to about 35 or 40. At this point, a squeal will be heard in the phones, and the grid leak is here used to diminish the squeal. When it is done, leave it alone, because the grid is then set, and does not need to be touched any more. Then setting the primary circuit into approximate resonance with the station desired (you can use the same setting that you do when using the regulation single circuit), rotate the plate variometer until the carrier wave of the station is heard. You will hear two squeals. It is directly between these two that the station is. When you have your receiver quiet, except for a frying spatter resembling fat in a pan, turn the plate variometer until it snaps out with a click. Then go back with the plate variometer and tune in until it is just below this point, and the music will be heard nice and loud, without any interference from any station. I can listen to WGY and not be bothered by any interference once the set is properly tuned, and because of the fact that the rotor of the coupler does not have to be bothered with much, the tuning is practically all done with the plate and grid variometers.

A word about capacity effects on this set would not be amiss. When shielding this set, I have found that better results have been obtained by grounding the shielding to the minus side of the A battery. The set should be shielded with either copper foil or gauze, because it is much easier to obtain good contact on copper than tin foil as tin foil corrodes quicker and good contact is harder to make.

Spread of Religion by Radio

SCHENECTADY clergymen whose services have been broadcast now look upon the radio station as a powerful gospel missionary. Words spoken in a church in the presence of a small group of people are given wings and travel to thousands of homes reaching the aged and the infirm and many who, but for the radio, would not hear a church service. Village churches, locked because of a shortage of ministers or inability to provide for a pastor regularly, now open their doors and the congregation worship with the Schenectady church membership via radio.

After every service letters reach the pastor from all parts of the country. One clergyman was recently told of two elderly women, too feeble to go to church, who dress each Sunday in their best finery and sit at their radio set, hats and gloves on, and devoutly listen to the service. During the scripture reading they follow the pastor in their Bibles and at the offertory they solemnly place a modest offering in a plate at their side. At the end of the service the money is sent to the pastor who has been speaking to them.

A lumberjack recently wrote one of the Schenectady ministers that he had heard a church service for the first time in eleven years, and that it had taken him back to his "Sunday School days."

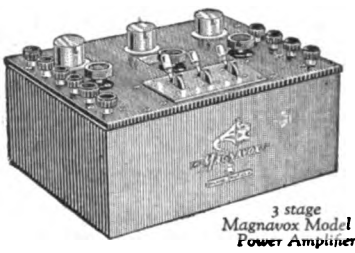
Radio Products



The Power Amplifier for your Magnavox Reproducer

The Magnavox Power Amplifier Model C, as illustrated, is a true *Power* Amplifier, and free from elements of distortion.

Switching from stage to stage is made easy by master switches. Any standard amplifying tube can be used.

Without Magnavox equipment, no Radio receiving set is complete.

Magnavox R3 Reproducer and 2 stage Power Amplifier . . . **$90.00**

R2 Magnavox Reproducer with 18-inch curvex horn: the utmost in amplifying power; requires only .6 of an ampere for the field **$60.00**

R3 Magnavox Reproducer with 14-inch curvex horn: ideal for homes, offices, etc. . . . **$35.00**

Model C Magnavox Power Amplifier insures getting the largest possible power input for your Magnavox Reproducer.

AC-2-C, 2-stage, $55.00
AC-3-C, 3-stage, $75.00

Magnavox Radio products can be had of good dealers everywhere. Write for copy of our new booklet.

Ford Building Big Broadcasting Station

A PRESS dispatch from Detroit says that at Dearborn, Mich., the largest radio broadcasting station in the world is being erected.

Henry Ford, still declining to parley with Ford-for-President clubs beyond formal acknowledgment of their letters, and put into a bad humor by newspaper stories of the boom, has made up his mind, it is understood, to talk straight to the American people in the future.

A well-defined report has it that Mr. Ford is going to put up a new kind of Presidential campaign. He is not going to tour the country and make speeches or give interviews in the newspapers. He is going to use the air instead of special trains and printing presses, so it is said.

His radio broadcasting station will put him in direct touch with every part of the country, and he will tell the voters himself, the report continues, when the great moment arrives. From then on he is expected to wage his battle for the Presidency by wireless.

Westinghouse Wins Over De Forest—Latter Guilty of Contempt of Court

IN a decree recently handed down by the United States District Court of the Southern District of New York the De Forest Radio Telephone and Telegraph Company was found to have been guilty of contempt of court in further infringement of the Armstrong regenerative patent. This decree is as follows:

1. That the De Forest Radio Telephone and Telegraph Company, the defendant herein, has been guilty of contempt of court in that it, after due notice of the injunction herein of May 27, 1921, prohibiting infringement of the Armstrong Patent No. 1,113,149, has committed, without license or authority from the plaintiffs, or either of them, the following acts of direct and contributory infringement of the said patent; namely:

(a) Defendant has sold radio-receiving sets, adapted and intended by it to infringe said patent, such sets containing variometers made and sold to the defendant by the Chicago Radio Laboratory, a licensee under the said Armstrong patent.

(b) Defendant has sold radio-receiving sets, adapted and intended by it to infringe said patent, such sets having been purchased by it from the Cutting & Washington Radio Corporation, a licensee under the same Armstrong patent.

(c) Defendant has sold radio-receiving sets, described as Type B in the order to show cause of April 19, 1922.

(d) Defendant has sold radio-receiving sets, described as Type J in the order to show cause of April 19, 1922.

2. That the De Forest Radio Telephone and Telegraph Company shall pay to the plaintiffs the sum of $9,250 to reimburse plaintiffs for expenses connected with the presentation of said violations, and shall also pay to the plaintiffs the sum of $750, which has been paid by the plaintiffs to the master as one-half of his fee.

According to the Westinghouse Electric & Manufacturing Company the above mentioned types—B and J sets—were non-regenerative as sold, but were made by the De Forest company in such a manner that they were adapted to be changed into regenerative sets, and, it is alleged, were sold by it with the intent that they be so changed.

Mogul Electric Company Enjoined Under Armstrong Patent

ON June 13, 1923, the Westinghouse Electric & Manufacturing Company, owner of the Armstrong regenerative or feed-back Patent No. 1,113,149, brought suit in the United States District Court for the Southern District of New York with application for preliminary injunction against the Mogul Electric Company, of New York City, the infringements complained of being the sales of certain radio-receiving sets made by the W. B. L. Radio Company, of Newark, N. J., which had been non-regenerative when obtained by the Mogul Electric Company, but were changed over by it to regenerative sets in violation of the Armstrong patent.

After the filing of the suit the Mogul Electric Company submitted to a decree enjoining it from further infringement of the patent.

Radio Trade Notes

R. F. YATES, former radio editor of the New York *Evening Mail*, has been appointed sales and advertising manager of the Electrad Corporation, 428 Broadway, New York City.

* * *

John C. Mitchell, 121 West 77th Street, Portland, Ore., has opened a manufacturing and distributing concern. He would like to represent eastern manufacturers on the Pacific Coast.

* * *

Sicon Radio Mfg. Company, 19 South Wells Street, Chicago, Ill., is said to be ready to buy anything required in the making of crystal sets.

* * *

General Supply Company, 144 North 13th Street, Lincoln, Neb., is reported as being in the market for tubes and loop antenna.

A. E. Hancock Co., 908 Congress Avenue, Austin, Tex., now a radio retailer, will open a jobbing business next month.

Injunction Secured Against Radioceive Company

THE International Electrical Supply Company, 29 Broadway, New York, has secured from Vice-Chancellor Badres an injunction against the Radioceive Manufacturing Company, 368 Jelliff avenue, Newark, N. J., prohibiting the latter from selling radio headsets in New England, New York and New Jersey. The New York company alleges that the Radioceive Manufacturing Company contracted, on April 27, to permit it to handle exclusively this territory.

Next Program of WGY Is a Good One

WGY, the favorite radio station in the great vacation grounds of the Thousand Islands, the Maine coast and woods, the Adirondacks and the Catskills, has a good program to offer for the week of July 15.

Sunday morning and evening, July 15, the services of the First English Lutheran Church of Schenectady will be broadcast. The sermons will be delivered by the Rev. Herbert D. Shimer.

The Troy Music Study Club will offer the program for Monday night. Ruth Don, a concert pianist; Everett T. Grout, tenor, and Alice Clough-Wilsey, violinist, will give the Tuesday program, July 17.

The Salvation Army Band of Schenectady, N. Y., a favorite organization with WGY listeners, will give a concert Thursday night, July 19. Samuel Slater is the director. The band will be assisted by Mme. Chantemerle, reader, who will give readings from "Les Miserables" in French.

Two concerts will be broadcast by WGY Friday evening, the first at 7.45 and the second at 10.30, Eastern Standard Time. The early program will consist of piano, soprano and baritone solos. At the later concert the Solka Orchestra will give a program of Polish music. Miss Ethel Thomas, soprano, and James Early, pianist, will assist.

Mail Service Radio Changes

THE Air Mail Service, Post Office Department, has ceased to utilize the radio circuit between Reno and the naval radio station at San Francisco, a leased wire service having been inaugurated by the Post Office Department between those points. In discontinuing use of the radio circuit the Air Mail Service expressed its thanks to the Navy Department for the efficient service rendered them for the past three years. Air Mail Service traffic previously handled by the naval radio station at Chicago has been taken over by the Post Office Department station at Maywood, Ill.

Wired Wireless in Germany

EXPERIMENTAL work in wired wireless is progressing in Germany, Consul Richardson advises the Department of Commerce. Recently communication was effected between Berlin and Stolp on the Baltic coast over a 400-kilometer line. This high-frequency telephone line has been turned over to the federal post authorities by the firm of Lorenz A.-G. Three calls at a time were put through successfully—one on the normal wave length, another on a 45-kilometer wave and a third on a wave of 25 kilometers. Instead of cathode tubes a special high-frequency generator was used.

Spielman Company Moves

THE Spielman Electric Company, Inc., New York City, are moving into larger and more convenient quarters at 311 West 59th street. The move was necessary because of the greatly increased demand for the firm's line of Seco radio products. A new set is the latest addition to their line of specialties. M. H. Spielman is president of the concern, and John J. Monahan is sales manager.

What Radio Enthusiast Is Going to England?

RADIO WORLD would like to get in touch with a radio enthusiast, professional or amateur, who intends to visit England this summer. Please address Editor, RADIO WORLD, 1493 Broadway, New York City.

Give It to the Sick Veterans, Doctor!

DR. DONALD M. GILDERSLEEVE, a radio enthusiast, of 169 Prospect Park West, Brooklyn, N. Y., informs RADIO WORLD that he has a six-tube receiving set which he is willing to donate to a worthy cause.

RADIO WORLD suggests that the doctor present the set to the Veterans' Mountain Camp, Paradise Point, Big Tupper Lake, N. Y. This is a hospital home for veterans of the World War who have incurred disability since their honorable discharge from the army, and, due to government red tape, are barred from treatment in government hospitals. The Veterans' Mountain Camp movement was started by several posts of the American Legion, and is sponsored by them. It is now a going outfit, and is doing great good to men who otherwise would have to suffer in silence. Radio supplies, clothing, books, magazines, sweaters, etc., will be received with gratitude by the doctors in charge for the use of their patients.

For the information of Dr. Gildersleeve and other readers of RADIO WORLD donations should be addressed as follows: Veterans' Mountain Camp, Horseshoe Station, N. Y.

"Leviathan's" Shore Telephone Service

THE S.S. "Leviathan" includes in her remarkable electrical equipment a three-position private branch exchange switchboard capable of serving 600 telephones placed in the cabins and at convenient points about the vessel. When the big ship is moored to her New York dock those on board may communicate with all points covered by the Bell System, which is nation wide.

The telephones will be placed in service as soon as the vessel is moored to her pier, and they will not be disconnected until the order comes to cast off. The New York Telephone Company explains that, while telephone connections have been made heretofore between shipboard and shore, nothing quite so elaborate as the apparatus on the "Leviathan" has ever before been attempted.

Help for Charley Barrett

A LETTER signed Charley Barrett and bearing the address of 36 Broadway, Saranac Lake, N. Y., was published in Radio World for June 30. Mr. Barrett, who is living at Saranac Lake because of tubercular trouble, requested that some one donate to him a radio set outfit in order to make life more interesting.

Theodore Seebach, of 53 St. James Street, Elmhurst, Long Island, N. Y., telephoned Radio World just as it was going to press saying that he had a radio set that he will contribute if some one will supply three tubes for it.

Now let us see if we can't get Charley Barrett in a happy mood right away.

Coming Events

AMERICAN RADIO EXPOSITION, Grand Central Palace, New York City, October 6 to 13, 1923. J. C. Johnson, general manager.

ANNUAL HOME AND CITY BEAUTIFUL EXPOSITION, featuring radio exhibits, Atlantic City, N. J., June 16 to September 8, 1923.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEER, Pacific Coast convention, Del Monte, Cal., Oct. 2-5. F. L. Hutchinson, 33 West 39th St., New York.

Manufacturers, Here's An Itinerant Salesman!

EDITOR, RADIO WORLD: I am contemplating traveling by auto from here, going west and return. Having had all kinds of experience with radio outfits and instruments I believe I am well qualified to sell the same to retailers. Here is my plan: I make no city over 50,000 inhabitants down to 1,000. With my auto I stop on the street of a city at night, light my lamps and demonstrate the set I sell and the parts, too. I also give a lecture on radio. When I am through I take the names of prospective buyers and turn the same over to some retailer who handles the parts I sell. I then go to the next town and repeat the above. I expect to start the first week in August. I have the backing of the Bureau of Standards here, as well as recommendations from the best business men in this city.

What I want you to do is to get my name before reputable radio manufacturers.

I am a great booster for RADIO WORLD, which I have taken for over a year. I still have every issue, and would not take a fortune for same unless they could be replaced.

Faithfully yours,
FREDERICK BUTTS.

604 Q St., N. W.,
Washington, D. C.

Mr. Hovey, of Oklahoma, Says Business Is Good

MR. O. H. HOVEY, manager of the Southern Radio Supply Company, Perry, Okla., got out a circular last week. It was printed in two colors on letter-size sheets. It carried Mr. Hovey's dignified portrait and this bald assertion:

"It would make a cat laugh to hear some of the radio manufacturers and dealers joining in the song 'Business is going to be good this fall after the static and hot weather is over.' Oh, hell! Business is good right now if you have any 'pep' and know how to use it. Right now I am selling and installing more radio outfits each week than any other one man in the state of Oklahoma. The reason? Because I advertise right."

And to prove the last assertion Mr. Hovey is sending out copies of the Perry *Republican* carrying two ads from his firm—one of them six inches, three columns wide.

New Radio and Electric Firms

Quinplex Radio Corp., New York City, $500,000; M. L. Lewis, A. Wellman, M. Christeleit. (Attorney, C. Milliken, 36 West 44th St.)

Consolidated Radio Call Book Co., New York City, has changed its name to Conrad Co.

The Shiloh Light & Power Company, Statesville, N. C., has been incorporated with a capital stock of $10,000 by H. M. Morrison, G. W. Nash and S. G. Caugill.

The Bancroft Light, Heat & Power Company, Ltd., Bancroft, Ontario, Canada, has been incorporated with a capital stock of $1,000,000. Donald L. Cameron is director.

Don't Try It!

Mr. D. F. Hamm, Cor-sur l'Andouillette, Kan., inquires:

Q. 1. I have read in your columns of using a transformer instead of batteries. There is a transformer on the electric light pole back of our house. If I connected my set to this would it carry farther?

A. 1. Fine dust from the eruption of Mount Krakatoa fell 3,000 miles at sea.—*De Forest Stand-By.*

IMPORTANT NOTICE

While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

Sweden's Strong Position in Telephone Industry

AN illustration of Sweden's strong position in the telephone market of ten countries is provided by the annual report of the L. M. Ericsson Telephone Company and affiliated concerns. This gives the net profits of the parent company for 1922 as approximately $600,000 and a dividend of 5 per cent. was declared.

Among the subsidiary concerns the British company declared a dividend of 8 per cent. and the Finnish, 15 per cent. The plant in Petrograd has been nationalized and is still in control of the Soviet. In Austria and in Hungary the Swedish telephone industry has been particularly active. In Vienna the capital stock has been increased from 3,000,000 Austrian kronen to 150,000,000, and last year's dividend on the new capital was 50 per cent. on the old capital.

The Warsaw company has increased its equipment to 37,000 instruments, and last year's business showed good returns. The Ericsson-Mexico system now has nearly 17,000 subscribers, and the dividends were 12 per cent., the net profits amounting to more than $180,000. In Buenos Aires and in Entre-Rios, Argentina, the two newly organized affiliated concerns, while showing excellent prospects, have not been operating long enough to bring any great profit. The profits of the Dutch company have been added to the reserves, while the companies in France and America have been holding their own.

WGY Players Reach Tremendous Audience

By C. D. Wagoner

A TURN of the dial gains you admission to the radio drama. Tune your radio set to station WGY and at least one evening a week you will hear an entire play, sometimes a comedy drama, a farce or melodrama.

For nearly a year now the General Electric Company station at Schenectady, N. Y., has been offering dramas by radio one night a week and during that period the little group of actors making up the WGY Players has had the largest audience ever before accorded dramatic offerings. Just how large that audience is is difficult to estimate. There are at least 2,000,000 radio sets in the country and of that number 1,500,000 are almost nightly within range of WGY. Many of these sets have loud speakers or extra phones enabling groups to listen-in. The number of people who have heard the WGY Players in the continuous run of 43 weeks is anybody's guess.

Edward H. Smith and a half dozen actors were engaged about a year ago to produce Eugene Walter's play "The Wolf" at WGY. It was something entirely new; it was contended by many that the radio audience would be unable to follow the play with any degree of interest because of the absence of scenery and because they could not see the players. Voice alone, it was contended, would not be sufficient to put over dramatic climaxes.

From the very first the radio drama was a success. Letters veritably poured into the station asking for more. Mr. Smith, formerly an actor and director on the professional stage, was engaged to produce one show a week.

This work was undertaken in a serious and thorough manner and for months many of the greatest successes of the stage have been going into the air reaching untold thousands who, but for radio, would never have had an opportunity of hearing the plays. During the past winter when farmers in many parts of the country were snowed in, cut off from the mails, the village and in many cases their nearest neighbors, radio programs went out to relieve their loneliness. The farmer, the woodsman, the keeper of the lighthouse along the Atlantic coast, were enthusiastic in expressing their appreciation of the dramas.

Mr. Smith and his players have pioneered in the art of the radio drama; they have had to develop a new technique. It was found necessary to make occasional changes in play manuscripts especially where a climax depended upon sight for its appreciation. The entrance to or departure from a room by one of the characters had to be indicated by sound, as a closing door. A bell helps somewhat in announcing a newcomer to the invisible stage. Various sound devices were created to produce atmosphere. A telegraph key and an imitation of an engine whistle were simulated by devices similar to those used on the stage.

The performer was greatly handicapped at first because he had depended a great deal upon the presence of his audience. Facial expressions were no help in interpretation; strong emotion could be conveyed only by vocal tone. To help the performer to a realization that his work was heard and appreciated WGY requested the radio audience to write their "applause" and this they have done by the thousands. The radio actor now "sees" his audience but an audience made up of all conditions of men, and finds inspiration for his work in applause, not of hand-clapping but words written.

A group of employees at the plant of the General Bakelite Company, Perth Amboy, N. J.

Interesting Broadcasting Coincidence

WITH nearly 600 radio broadcasting stations in the air, many of them at the same time, it is not unusual for an operator to pick up two or three stations at the same time. Then begins the delicate task of tuning out all but the desired station, a task frequently impossible and always trying to the temper.

It is most unusual, however, for a fan to secure dual reception and discover that both stations are playing the same tune in the same key and tempo.

This occurred Tuesday evening, May 22, at 8.21 o'clock. A Providence, R. I., radio fan recently wrote WGY, the Schenectady station of the General Electric Company that he had heard the Radio Four sing "Dixie" from WGY at the same time that WEAN, the station of the Shepard Company in Providence, was sending out a phonograph record of "Dixie," a banjo solo with piano accompaniment. Part of the letter follows:

"Just once you faded out and WEAN was playing a banjo solo with piano accompaniment, 'Way Down South in Dixie.' What was our surprise to hear your minstrels come in on the same song, in the same key and same tempo and together, the two companies so many miles apart, finished the verse and chorus."

The log of WGY showed that the Radio Four had sung "Dixie" on the night and at the time given by the correspondent and R. F. Shepard, vice-president of the Shepard Company has reported that his station broadcast the same number at that time.

Special Church Services from WGY

WGY will provide special Sunday evening religious services from the studio in Schenectady, N. Y., during the months of July and August when few churches are holding evening services. The speaker Sunday night, July 8, will be the Rev. W. E. Compton, pastor of the Mont Pleasant Reformed Church. At 9:30 o'clock in the morning the services of the First Methodist Church will be broadcast.

Dr. Sigel Roush, lecturer, journalist and traveler, will give another of his series of travelogues. His subject Monday, July 9, will be "A Trip Through India." The lecture will be divided into three parts.

Two one act plays, "A Wall Street Romance" and "A Minuet," will feature the program of July 10. Thursday night will be farmers' night at WGY. W. W. Norton, of Hartford, N. Y., will give an address on "The American Farmer and His Problem." At 10:30 o'clock, the late Friday evening concert, talent supplied by the Dolgeville Exchange Club, of Dolgeville, N. Y., will appear.

Fifty-two issues for $6.00. Subscription Department, RADIO WORLD, 1493 Broadway, New York City.

Radio and the Movies in Canadian Rockies

IN addition to being the first motion picture company to use aeroplanes in an actual story woven around the Canadian North Woods, the Cosmopolitan company, making the motion picture "Unseeing Eyes," has the distinction of having introduced radio in the Canadian Rockies. During the filming of scenes in the rugged country around Banff, Lake Louise and in the Selkirk Range members of the company were kept in contact with the outside world through the medium of radio.

When Director Griffith left for location in the Canadian Rockies he arranged for the transportation of a powerful heterodyne set. Through it messages were received from as far off as Los Angeles. Lionel Barrymore, Seena Owen and other members of the company soon became great radio fans, and listened in every night.

According to Director Griffith messages were received from KHJ, Los Angeles; KSD, St. Louis; WOR, Newark, N. J.; WJZ, Newark, N. J.; CFAC, Calgary, Alberta, and many other sections of the United States and Canada. "Unseeing Eyes," adapted to the screen by Bayard Veiller from Stanley Weyman's famous romance, is rapidly nearing completion.

Memorial Scholarship Man Takes First Honors

ARTHUR MARTENS, whose eligibility for entrance to Carnegie Institute of Technology at Pittsburgh was questioned because he had never attended High School, was graduated as honor man at the recent commencement. He stood first among 120 students who received enginering degrees.

His entrance application was accepted only after a special plea of C. S. Coler, manager of the Educational Department, Westinghouse Electric & Manufacturing Company at East Pittsburgh, his preparatory work having been under Mr. Coler in the Westinghouse Technical Night School.

The University of North Carolina reports that another Westinghouse scholarship man, H. C. Klingenschmitt, stood No. 1 in seven studies and No. 2 in one study for the year just closed.

Both of these men attended college as a result of being awarded War Memorial Scholarships by the Westinghouse Electric & Manufacturing Company. Several such scholarships are awarded every year to company employees and members of their families.

Subconscious Code Practice

LEARNING the code while you are sleeping may be perfectly simple for some one that is a good sleeper, but how in Tut's Treasures is a man who is a victim of insomnia ever going to learn the code that way?" was a question asked by one of our readers.

That's easy compared with a man who is a somnambulist. He would have to have a portable set strapped to his back.

MERRY CHRISTMAS!

We are installing eight tube superheterodyne: following new receiving sets, at thirty percent off, for immediate disposal:—

(a) **Melco Supreme:**—4 tubes. Magnificent.

(b) **Davidson:**—5 tubes. Quality with terrific volume.

EVERY RADIO FAN should have these two books, "101 Receiving Circuits" and "Six Successful Receiving Sets." By M. B. Sleeper. They are the most up-to-date radio books for the fan who likes to make his own, and will help you out and save you many times their cost. Both books are full of illustrations. Price, 50c. each, with 10c. extra for postage, or both for $1.00 sent postpaid. COLUMBIA PRINT, 1493 Broadway, New York City.

DYNAMO BUILDING FOR AMATEURS—Or How to Construct a Fifty Watt Dynamo.—By Arthur J. Weed. A practical treatise showing in detail the construction of a small dynamo or motor, the entire machine work of which can be done on a small foot lathe. Dimensioned working drawings are given for each piece of machine work, and each operation is clearly described. This machine, when used as a dynamo, has an output of fifty watts; when used as a motor it will drive a small drill press or lathe. It can be used to drive a sewing machine on any and all ordinary work. The book is illustrated with more than sixty original engravings, showing the actual construction of the different parts. Price, $1.00. THE COLUMBIA PRINT, 1493 Broadway, New York City.

Construction of New Type Transatlantic Receiving Sets

By M. B. SLEEPER

Fully Illustrated. Price 75 Cents

IN addition to the listening to ships and broadcasting stations on short wave lengths there is a peculiar fascination about listening to the high-power telegraph stations of England, France, Germany, Russia and Italy as well as those located in the Pacific Ocean and the Oriental Countries. It is much easier to do this than most people imagine. The sending is very slow, a feature of assistance to the beginner in telegraphy. Several types of receiving sets for this task are described. Detectors, amplifiers, oscillators, etc., for long distance reception are also described. Suggestions for the operation of relays by the signals and the reproduction of them on a phonograph are given. In addition there is some valuable data on home made wavemeters for testing and experimenting.

RADIO BROADCASTING MAP

FOR the benefit of those interested in Radio and those who are becoming interested, Rand McNally & Company have prepared a publication containing a wealth of information of greatest value. It shows, in the most comprehensive way, the location of the broadcasting stations, gives their classification, the call letters, wave lengths, ownership, etc., of each.

The Rand McNally Radio Map of United States is 28x30 inches in size. The locations of broadcasting stations are shown by distinctive symbols. The call letters of each station are given, also the wave lengths of each. The Radio Districts with numbers are shown in red and the Radio Relay Divisions are in blue. Time zones are included. Alphabetical lists of stations and alphabetical lists of call letters are in the margins. Convenient pocket form with cover.

ABSOLUTE TUNING PRECISION with

ACCURATUNE

MICROMETER CONTROLS

An accurate tuning instrument ten times more efficient than any vernier device. Micrometer control within the dial itself permits hair splitting adjustments never before possible. Operates every plate of condenser and eliminates necessity for vernier plate. Fits any standard 3/16" or 1/4" instrument shafts. Attractive and durable. Silvered dial with neatly engraved graduations. Black or brown bakelite knobs. If your dealer cannot supply you send $3.50 direct to us for this wonderful instrument. Fixt-Post Inductance switch and Rheostat dials to match.

Radio Enthusiasts Tie Up French Wire Service

"Listeners in" who daily hear the concerts broadcast by the Eiffel Tower wireless are accused of adding to the already great confusion and disorganization of the telephone and telegraph service of France, according to a press despatch.

Officials of the Telegraph Administration assert as an excuse for the irregular service that wires are being grounded everywhere by amateur wireless enthusiasts who do not know better than to connect their listening apparatus to telegraph and telephone wires.

The result, the officials state, is grounding and endless trouble for the Telegraph Administration. There is talk of issuing an order requiring everybody applying to the Administration for permission to install a wireless outfit to keep the official wires free.

American Radio Exports

DURING April, radio manufacturers shipped $224,195 worth of apparatus to foreign countries, an increase of $31,000 over March exports, according to compilations of the Department of Commerce. The total volume was over 64 tons, most of which went to Quebec and Ontario. These two provinces lead, receiving $65,325 worth, while the Virgin Islands stood second with $42,448 worth of apparatus. England was third and Mexico and Cuba followed. Thirty-four countries purchased radio equipment in the United States during the month, varying in value from $11 upward.

A report from the Netherlands shows that that country imported $59,280 worth of radio goods against imports valued at $27,300 during the first quarter of 1923. The trade in radio materials and equipment in the Netherlands has increased both in imports and exports over the first quarter of 1922 by several thousands of dollars.

"Jimmie" Listens In

(C. Fotograms)

"Jungle Jingles" were made expresely for this particular audience, who is shown heartily laughing at a joke cracked by one of the members of the Anti-Saloon League at a banquet of the Master Brewers' Association on the advent of the repeal of the Mullan-Gage Law. The illustration shows Jimmie all decked out in his best Sunday suit. He has two—his Sunday suit and his birthday suit.

Effect of the Weather on Radio

AS the warm days of summer come you will probably notice that some of the stations you have been hearing at a distance will come in weaker, and perhaps you will cease to hear some of them for a time. Like some of us poor mortals, says the director of Station WOC, the radio waves do not travel so far on the hot, sunny days as they do on the crisp, cool ones, and they prefer travel by night rather than by day. You can make an interesting study and at the same time contribute something to the knowledge of radio telephony if you will keep a record of the weather on days when your reception is exceptionaly good or when you have difficulties. Such a study, continued for a considerable length of time, may lead to the solution of some of your difficulties. It should be worth trying.

Try This Next Time

A READER has written a nice little note to us, telling us that we may read it and publish it at our own discretion. He states that he will not be responsible for the consequences, and will absolutely refuse to pay our hospital bills in case we come in personal contact with any of our readers. We never did like to take a dare—from any one; so here goes!

". . . And, furthermore, I have found out that if you start to chew on celery or a nice, hard apple while receiving a church sermon that you will not be bothered by any interference. As a matter of fact the sermon will not bother you either—if you chew vigorously enough."

Radio World, 52 issues, $6.00.

Subscribe direct or through your news dealer. $6.00 a year, $3.00 six months, $1.50 three months. Radio World, 1493 Broadway, N. Y. C.

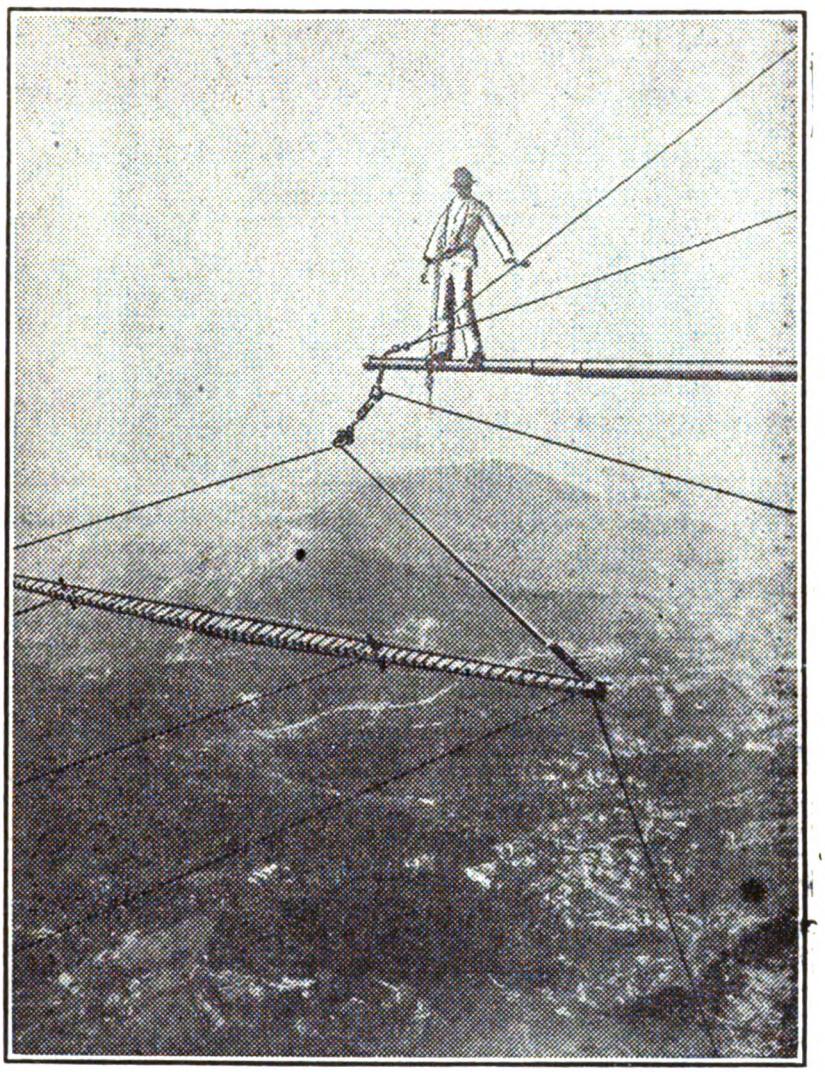
The Highest Radio Station in the World



One Antenna Spreader of Station SPC

SPC, the radio telephone station recently installed by the Westinghouse Electric International Company, on the peak of Mt. Corcovado, overlooking the city of Rio de Janeiro, Brazil, enjoys the distinction of being the highest radio station in the world. The peak of the mountain is more than 2,100 feet above the city and from the station one may have a most wonderful view of the country for miles around.

While erecting the antenna for the station workmen were given many thrills and many times faced death when the slightest misstep would have meant a plunge into the depths below. The illustration herewith shows a workman standing out on one of the poles to which the antenna spreaders are attached.

SPC was the feature of American exhibits at the Brazil Centennial.

Radio World "Doubled Value of My Set"

EDITOR, RADIO WORLD: I desire to say that I am extremely well pleased with RADIO WORLD. Mr. C. White's Wave Trap, described in the issue of April 21, 1923, has doubled the value of my set; not only doing that for which it was designed, but giving me distance and clearing up all distortions of sound. Therefore I accept with alacrity your offer to send RADIO WORLD, 52 issues, and *Radio*, a San Francisco magazine, for one year for $6.00, in accordance with the enclosed slip.

Yours very truly,
W. G. LITTLETON.

RADIO HELPS YOU ENJOY YOUR VACATION IN THE WOODS

(C. Keystone Views) (C. Kadel and Herbert)

This composite picture shows how universally people are taking radio into consideration when they plan their vacations. The illustration on the left shows two California girls enjoying a concert while roughing it in the Arrowhead Woods, 70 miles from Los Angeles, California. On the right you can see Peggy Stahl and Rona Oakley getting their set ready up in the Adirondacks, in New York State. Miss Stahl is looking for a likely place to string her aerial, while Miss Oakley is giving the tubes a careful inspection after the ride over the rough mountain roads. No trip to the country is complete these days without a radio set, whether it be a simple crystal receiver or a five-tube set with loud speaker. No matter whether it is a camping trip to the woods or a vacation at one of the large country clubs or resorts, you are always in demand when you bring your receiving set.

Anybody Can Now Talk to Everybody by Radio

A NEW possibility and another utility of the radio was disclosed at Boston last week when it became desirable for a young man who was away on his honeymoon to return home at once, says an editorial writer in the New York *Times*. His mother had been taken desperately ill, and was pathetically eager to see him, perhaps for the last time. All that was known about the young couple was that they were "somewhere in New England," for, after the manner of their kind, they had veiled in deep secrecy the destination of their nuptial journey. They went away in an automobile and purposed to do all their traveling in it, stopping wherever fancy decided and staying there only as long as they pleased.

With no fixed address, even in their own minds, the prompt finding of the honeymooners would have been, until recently, impossible. Now it could be done simply and easily, and was. Nothing more was required than the "broadcasting" of a message to the bridegroom, telling him the facts. It reached without delay the secluded inn at Lost River, N. H., where he happened to be, not because it was sent there, but because it was sent out of Boston in every direction.

This is "paging" of a sort not even imaginable a few years ago, and obviously in the same way practically anybody in the more civilized parts of the world who wants or is willing to be found can be told without much loss of time that somebody desires to see him. Such calls will reach the far expanses of the ocean as well as of the land, for there are few of either, nowadays, that do not contain at least one instrument for receiving radio dispatches.

And before long, probably, the paging message can be an audible summons—one of spoken words, directly understandable and with the speaker's voice recognizable by the receiver. Then will the once all-conquering element of distance receive a stunning blow and give up the fight.

Already it is possible to get into direct oral communication with a considerably larger fraction of the earth's inhabitants than commonly is realized. Probably there are not more than 1,000,000, if as many, of the 100,000,000-plus people in the United States who cannot be summoned to a telephone, their own or that of somebody else willing in case of need to take the trouble to serve a neighbor. In some cases it might take an hour, or even a day, to "get" the person wanted "on the wire." It would cost money if the distance approached the transcontinental, but the price would not be prohibitive when a serious emergency was to be met or important business was to be done.

There seems to be no present probability that the radio wholly will replace or diminish materially the use of either the telegraphy or the telephony that is done over wires, but radio certainly will supplement both to an extent constantly broadening as the years go on. The prospect is not wholly pleasant to those who cherish the privileges and rights of privacy—of getting completely away, now and then, from their fellow men and women—but on the whole the balance is in favor of progress and change. That is fortunate, for neither can be prevented, and we must make the best of both.

He Had the Right Idea

TEACHER: "Johnnie Jones, explain the meaning of the expression 'multitudinous accomplishments.'"

Johnnie: "Building your own set, getting it to work and then selling it for more than it cost you and havin' the fella tell his friends that it was a bargain."

Fifty-two issues for $6.00. Subscription Department, RADIO WORLD, 1493 Broadway, New York City.

LATEST BROADCASTING MAP FREE to RADIO WORLD SUBSCRIBERS

The latest radio broadcasting map of the United States and Canada, containing all the new allocations and changes, is offered *free* to subscribers for Radio World who send in their subscriptions within the coming four weeks. This map is printed on fine map paper stock and has just the information you want regarding broadcasting stations throughout the continent, including army and navy stations.

If you are already a subscriber you can get this map by renewing your present subscription now.

Send direct to this office or you may subscribe thru your newsdealer who can send your subscription direct to us.

Use the coupon attached.

RADIO WORLD FREE MAP SUBSCRIPTION BLANK

Radio World,
1493 Broadway, New York.

For the accompanying $3.00 please send me Radio World for six months (26 numbers) beginning with issue dated .....and also, without any expense to me whatsoever, the latest radio map as advertised.

Name .....

Address .....

City and State.....

If you wish two maps, one for yourself and one for a friend, send $6.00 for a yearly subscription and the two maps will be sent to different addresses if you wish.

VOLUME THREE OF

RADIO WORLD

[Entered as second-class matter, March 28, 1922, at the Post Office at New York, N. Y., under the Act of March 3, 1879]

A Weekly Journal, Published Every Wednesday and Dated Saturday, by Hennessy Radio Publications Corporation from Publication Office, 1493 Broaday, New York, N. Y. Telephone: Bryant 4796.

Vol. III, No. 17. Whole No. 69 July 21, 1923 15c. per copy, $6.00 a year

A Midget Set That Gets DX

By Dick Roberts

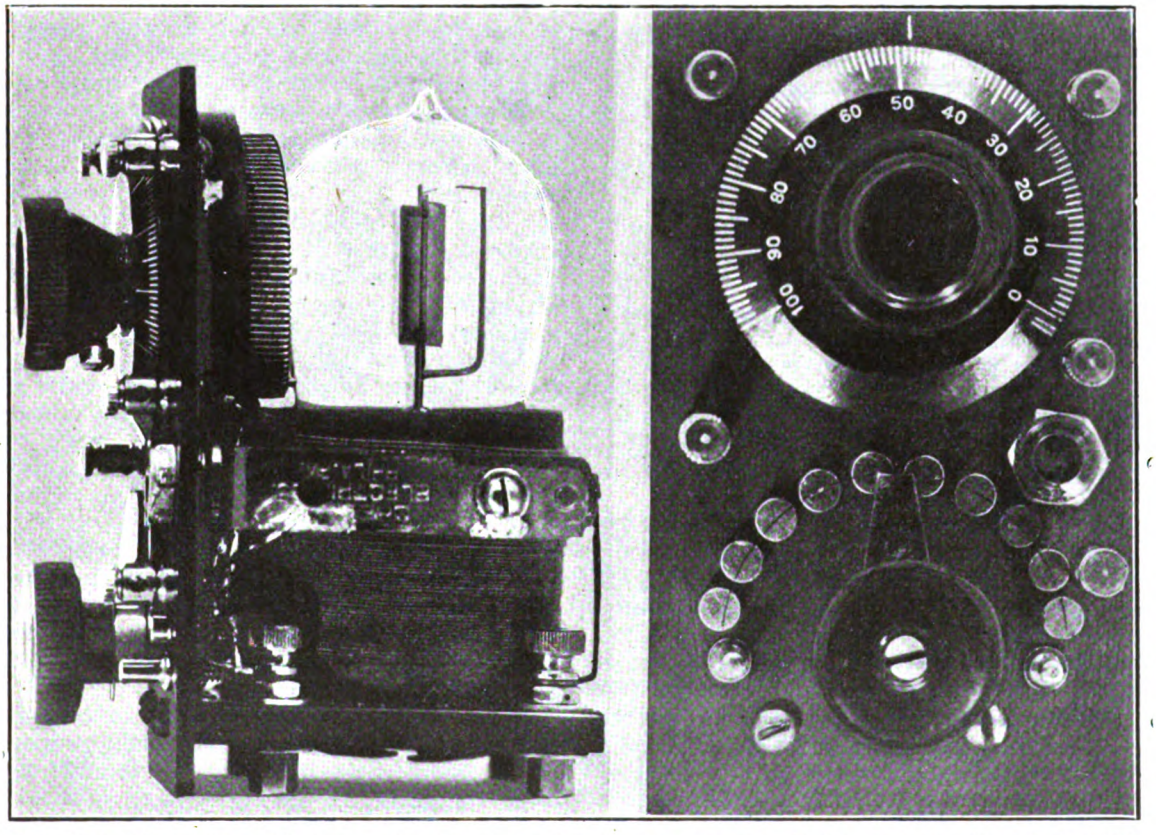
I HAVE seen several articles on miniature sets, all of them extremely practical and noteworthy. Being of an inquisitive turn of mind I thought I would try the construction of one of the "midgets" to see if they worked, and to satisfy myself that I could make it. Accordingly I determined to make it a tube set, and make it as small as I possibly could without seriously robbing it of its usefulness. The illustration showing the front view is the exact size of the entire set, so you can see for yourself my results.

The panel is 4¼ inches high by 2¾ inches wide and 2¾ inches deep, those being the exact dimensions of the tube socket base. All the apparatus is mounted on the socket and it was all constructed of standard parts.

The coil is wound of 80 turns of No. 28 SCC wire on a tube two inches in diameter. This tube is tapped every eight turns, making a total of 10 taps. The rheostat is a Fada (without vernier) the socket is a Signal and the jack is a Chelten.

The photographs were taken full size and show the construction and placing of all of the apparatus. You will note that the coil is placed over the base of the socket in such a manner that it takes up no more space than would naturally be taken up by the socket and tube itself. This is a feature that should interest the builders of small size sets.

The set uses no condensers or grid leaks whatsoever, none being used in the grid, the connection from the antenna going direct to the grid of the tube, and the plate connection coming direct to the under side of the jack thereby eliminating all wire in the plate side of the set.



Two views of the portable midget set constructed and described by Dick Roberts. The illustration on the right is a full size photograph of the complete set, and that on the left is a side view of the receiver showing all the apparatus mounted on the base of the socket.

I have used this set three nights after 11 o'clock and have heard the following stations loud and clear from Miami, Oklahoma, with no distortion, very little noise and very little trouble from interference. The stations heard were: WOC, WLAG, WHB, WDAF, WHAH, WSB, WGM, WOAW, WFAA, KSD, WMC.

A Long-Range Crystal Receiver

By Kenneth Malcolm, A.I.R.E.

THE amateur radio operators of but a few years ago knew of the vacuum tube only as they read about it in the books and periodicals. It was at that time that the crystal set was in its full glory. And, considering the apparatus available, some really remarkable reception was carried on. The writer had a friend living in Brooklyn who picked up the Naval station at Honolulu a number of times, using nothing but a loose coupler set with a crystal detector. A distance of 1,500 miles was not considered uncommon by anyone. Ships at sea, using the comparatively insensitive carborundum crystal, were expected to, and *did*, pick up "press" over distances of 2,000 miles. Today, although not a usual thing, radio fans pick up broadcasting over distances of 500 miles.

The favorite type of set was of the loose coupler variety, for with this arrangement a greater degree of selectivity could be obtained than with the tuning coil. The set to be described is of this type, embodying all the best features of the loose coupler outfit, with the windings designed especially for the broadcast

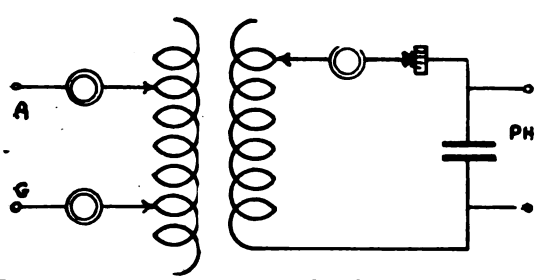

Fig. 1—Circuit diagram to be used with the set described. By connecting a variable condenser across the secondary, greater selectivity and easier control can be had.

wave lengths. Don't, however, imagine that a range of 500 miles is guaranteed—you might get it, but it is quite a sure thing that you will get every good broadcasting station within at least 30 miles.

Purchase an insulating panel ⅛-inch thick, 4⅝ inches wide and 4¾ inches long. Also two small rotary switches and 16 switch points, or taps. Another slightly larger rotary switch with 10 switch points is needed for the secondary. About 75 feet of No. 20 S. C. C. wire is needed for the primary winding and 100 feet of No. 26 S. C. C. wire for the secondary. Secure a set of detector parts, somewhat like those shown in the drawing. A phone condenser of from .001 to .003 mfd. capacity, two 3/16-inch round brass rods and a set of four binding posts complete the list of electrical parts.

Before the other work is started the panel may be carefully laid out, the holes drilled and the switches, detector and binding posts mounted. The drawings show plainly how this is done.

For the primary and secondary coils two tubes are needed. These may be of cardboard that has been impregnated with some insulting varnish, hard fibre, hard rubber, or one of the phenol condensation products One tube should have an outside diameter of 3½ inches, and the other an outside diameter of three inches. The walls should be about ⅛-inch thick in order to conform with the measurements of the other parts that will be mentioned. The primary, or larger tube, should be four inches long and the other 3½ inches.

Start the winding of the primary tube about ½-inch from the end and use the No. 20 wire. Wind on smoothly and evenly 72 turns making provision for taps on each of the first eight turns, and on every eighth turn thereafter. This should make 16 taps in all.

The winding on the secondary tube should be started about ¼-inch from the end and should consist of 100 turns of No. 26 wire. Provision for taps should be made at every tenth turn; this time the taps being taken from the *inside* of the tube. To do this, simply make a very little hole in the tube, where the tap is to come, and force through this hole a loop made of about an inch of the wire, then continuing the winding. Give the loop several twists to prevent it from pulling back through the hole.

Next we have to consider the wooden parts. Hard, well-seasoned wood should be used throughout. The base is 12 inches long, 5⅝ inches wide, and ¾-inch thick. A bevel around the top edge gives it a nice appearance. Two coil ends, 4¼ inches square, are needed for the primary tube. One of these should be ½-inch thick and the other must be composed of two pieces, each ¼-inch thick. A piece ⅜x4⅝x4¾ inches is needed for the top, and another piece ⅜x4¼x4¾ inches for the back. A piece ½x3x1½ inches is required for holding the ends of the coupling slider rods.

The only thing difficult in the construction of the set is making the tube fittings. However, if you have a little patience, a hand bracket saw will do the work very nicely. Find the exact center of one of the quarter inch end pieces by drawing its diagonals, and scribe a circle with a compass exactly 3¼ inches in diameter. This should be cut out with your saw, and if you are very careful, both the disk and the other part may be used. The disk should be mounted with two small brass screws on the exact center of the half inch end piece, as shown. Find the center of the other quarter inch end piece, and scribe a circle 3½ inches in diameter. Cut this out. The edge of this disk should be carefully smoothed with several grades of sandpaper, for it is to be used for the end of the secondary tube. Out of another piece of ¼-inch stock cut two disks 2¾ inches in diameter. Use glue and several small brass screws to fasten one of these to the center of the last mentioned disk. Glue and screw the two quarter inch end pieces together as shown in the drawing, so that the larger opening will be on the inside, or toward the tube.

Now the primary tube may be mounted. Place the end pieces on the tube and, when properly aligned, screw them to the base at the left end; the open end piece should be on the right side.

Next lay out and drill the secondary end piece for the switch and taps. The tap leads may now be soldered on and connected to the switch points, and the end fastened by means of several little screws through the tube. The disk for the other end of this tube should have a ¼-inch hole drilled through its center. Through this hole runs about a 12-inch length of double twisted flexible wire, which serves the purpose of connecting the secondary with the detector, the phone condenser and phone binding posts. A hole near the left hand end of the primary tube will allow it to pass through. After all the connections have been made inside the secondary, this other end may be fitted.

At some point near the bottom two parallel holes, about an inch and a half apart, should be drilled through both secondary end pieces, and to a depth of about

Dry Cell Eliminates Recharging

By Velma Carson

DRY cell vacuum tubes are beginning to displace storage batteries in radio receiving sets for the reason that they cost less and are more convenient to use. They are equally efficient for ordinary purposes.

Farmers are welcoming the use of dry cells because where they have no farm lighting system they have no way of getting storage batteries recharged unless they make a trip to town. And since this has to be done about every two months and costs at least a dollar it is a nuisance and an expense. Storage batteries cost around $15 apiece and only last, on the average, about three years. Besides the original investment a person has spent $36 in that length of time or $51 altogether.

You can buy enough dry cells for vacuum tubes for $50 to last ten years.

A dry cell costs 35 cents and can be used a hundred hours. There is no bother of re-charging or filling with distilled water every few weeks. It is put in the circuit, connected up, and then forgotten until it is ready to be thrown away.

A store of these tubes can be kept in reserve. They remain in good condition unused for six months. Nearly any electric shop in any small town carries them.

Another motive than economy prompts the use of the dry cell vacuum tubes and that is the convenience. Compared to the storage battery eight inches high and four inches in diameter the dry cell is only 2½ inches in diameter and 6½ inches high. It contains no acid likely to spoil things, is not heavy to cart, and does not take up a lot of space.

We can get more out of a dry cell by using it intermittently, i.e., with periods of rest in between periods of operation. We can get more out of it by keeping the current drawn from it as low as possible. What shall we do then? Be sure to turn off the filaments when the set is not in use. Do not run more than one tube from one cell. If you have two tubes, use two cells in parallel. When possible use two cells in parallel to supply one tube. One point to be remembered when connecting cells in parallel is not to use an old and a new cell. Their voltages will be different and will set up a local circulating current which will soon spoil the new one and will not improve the old one.

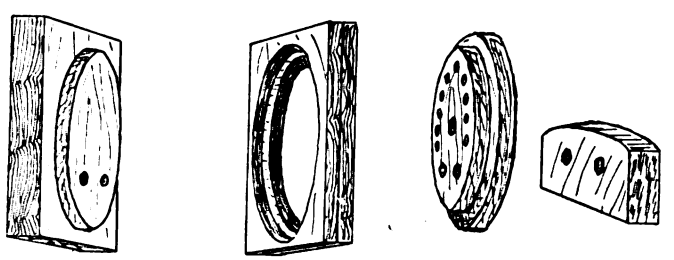

Fig. 2—Wood supports for the primary and secondary. They should be well seasoned. Dimensions are all given in the accompanying text.

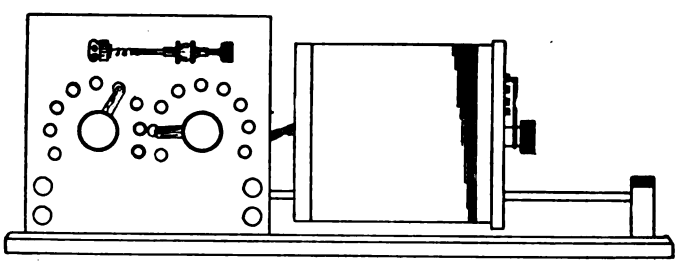

Fig. 3—The complete receiver as it should appear when finished. If care is taken in construction, and a good coat of alcohol stain applied, a very neat and serviceable instrument will be the reward.

(*Continued from preceding page*)

¼-inch in the left hand primary end piece and the rod support. Be careful to get these all in a perfect line, so that the rods may slip through easily. The rods may now be placed fitting them firmly in the left hand end, passing them through the both ends of the secondary and finally into the rod support. This latter piece may then be screwed to the base. If the work has been done properly, the secondary will slip into the primary tube very easily.

The panel may now be mounted and the connections made. The first eight taps of the primary coil are connected to the switch points of the left hand switch, and the other eight are connected to the right hand switch. One switch lever is connected to the aerial binding post and the other to the ground post. One of the flexible leads from the secondary is connected to one side of the detector and the other lead is connected to one of the phone posts and to one side of the phone condenser. The free side of the detector is connected to the other phone post and to the free side of the phone condenser. Be sure to solder all joints if you do not care to keep taking the set apart all the time.

The back and the top may now be fitted. If the wood parts have not been previously stained and varnished, it may be done now. After thoroughly sandpapering, apply some oil stain of the desired shade and color, and when perfectly dry, apply a coating or two of white shellac or transparent varnish.

The set will now be complete and the results that you get will be commensurate with the quality of the materials and the workmanship that you put into it. Also, a great deal depends upon the sensitivity of the crystal and upon that of the phones. Personally, I think that a good piece of galena is the best crystal to use, though some of the new synthetic crystals are very good.

The operation of the set is quite simple and, after a little practice, considerable proficiency will be acquired. By the use of the two switches on the primary, a single turn adjustment will be possible, affording the fineness of tuning that could be obtained with a slider. To tune in a station, put the secondary well within the primary, and adjust the detector as best you can—if you think it is out of adjustment. Set the secondary switch at some arbitrary value. Move the right hand primary switch until something is heard, then try to increase the intensity by moving the left hand switch. Next adjust the secondary switch and the coupling. If the results are not then satisfactory, and you think they can be bettered, play around with the detector a little. After a little experience, you will be able to make the adjustments almost intuitively.

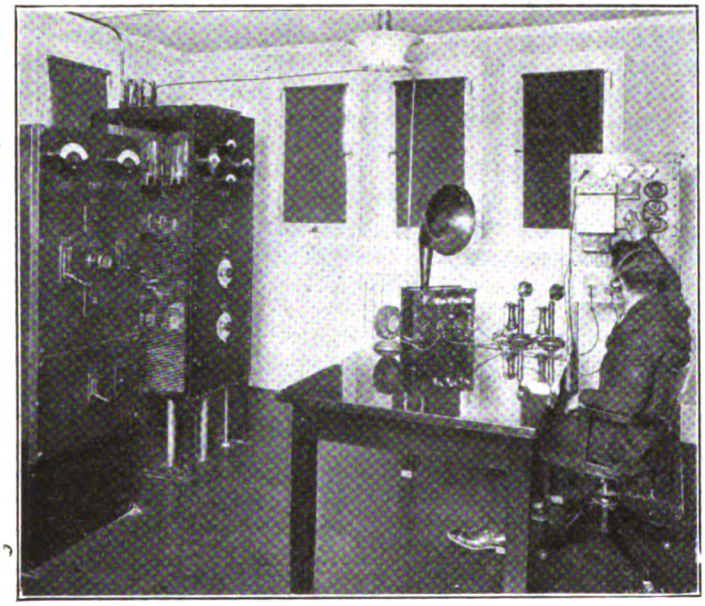
Col. Green's Radio Station WMAF

By C. W. Tucker

TO provide first-class radio programs for the people of New England and especially for his friends in and around New Bedford, Mass., Colonel E. H. R. Green has sponsored an innovation in broadcasting. Last Sunday night radio listeners heard the announcer say: "This is station WMAF, South Dartmouth, Mass. You have been listening to the



(C. Western Electric)

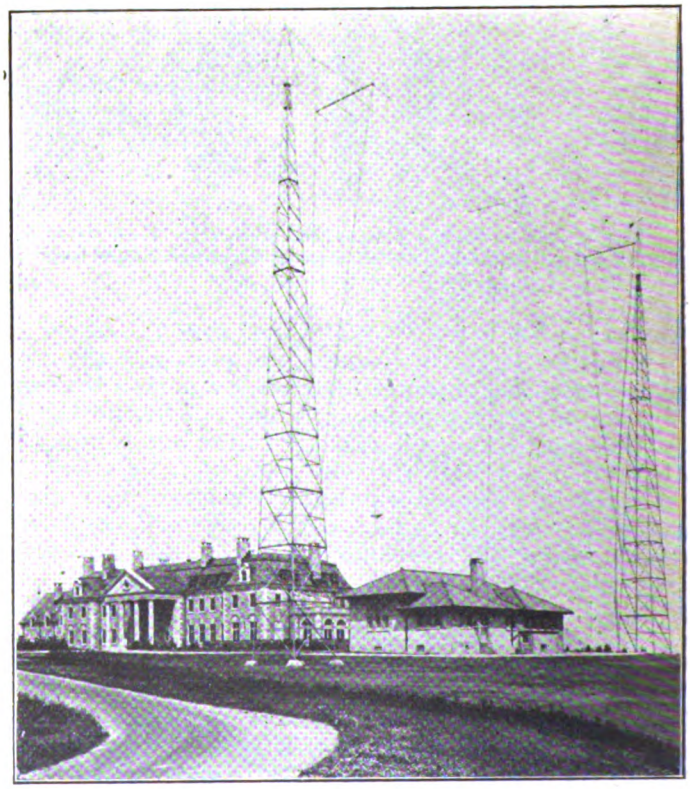
Apparatus room at WMAF. Here the operator regulates the volume of radio transmission and controls the entire power side of the transmitter.

musical program of the Capitol Theatre, 51st street and Broadway, New York City." Back of this simple statement is a modern miracle of electrical communication.

Realizing that New York was the center of artistic talent, Colonel Green arranged with the American Telephone and Telegraph Company that programs rendered for its station WEAF should be transmitted also over its telephone lines to the radio station on his estate, "Round Hills," where the speech and music control the radio set of WMAF just as if the performers were in the adjoining room. In the studio of WEAF is a sensitive microphone whose output is amplified through five stages and fed to a high-grade telephone circuit passing through Hartford, Providence and New Bedford. In each of these cities are test stations where the voice currents are amplified; and finally at Round Hills are four more stages, making a total of fifteen. The total amplification from transmitter to antenna reaches the enormous figure of ten billion times. Were it not that the energy of the transmitter is so tiny, and that much of the "gain" from each stage is dissipated in the intervening lines, all the power plants in the country could not furnish enough power to operate the last stage of amplification.

The building which Colonel Green erected for station WMAF is of tile and stucco, its lines harmonizing with Round Hills close by. Through the wide front doors one enters first a spacious reception hall, whose comfortable furnishings and broad fireplace make one feel at home. At the left are the office of the station manager, and the artists' retiring rooms. At the right, glass doorways lead to the studio, where local programs are produced. Blue brocade is hung loosely about the walls, so that reverberations may be damped to just the right degree. Deep chairs and a great davenport suggest that relaxation in which a performer can give the freest expression of personality.

From the main hall or the studio one enters the apparatus room, where stands the Western Electric 500 watt radio telephone transmitter. From the microphone in the studio, or from the telephone line from New York, tiny electric currents bearing the impress of the speaker's voice go through four stages of amplification and thence to the twin modulator tubes. Here they control the output of two oscillator tubes, thus sending out to the antenna a high frequency current whose strength is a faithful copy of the vibrations of the speaker's voice. The antenna itself, whence the other waves are radiated, is swung from two graceful steel towers 143 feet high. It consists of four wires, having a flat top 115 feet long, with lead-in wires falling 140 feet vertically to the transmitting apparatus. Power is furnished to the set at 14 volts for the tube filaments and at 1600 volts for the plate circuits, from a motor-generator set in an adjoining room. A radio receiving set is also provided, on which, as required by law, an operator listens constantly during transmission to pick up any distress calls from ships at sea.



(C. Western Electric)

Station WMAF showing the antenna equipment, the studio and transmitting room. Round Hills House, Col. Green's summer home, at Dartmouth, Mass., directly back of the tower.

When a program is to be produced, power is thrown on the set, and the wave length and antenna current are checked. Over a telegraph wire the New York control room is notified that all is ready. In New York, the announcer presses a button which makes the final

(*Concluded on next page*)

Digitized by Google

(*Concluded from preceding page*)

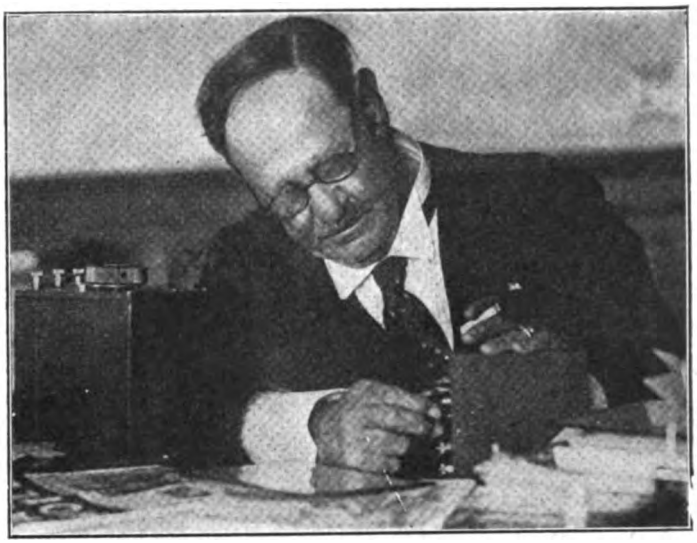
connection from the microphone, and then introduces the performer to the invisible audience. During the program, the control operator listens constantly by a head set or a loud speaker to what is being transmitted, and adjusts the degree of amplification so as to fully load, but not overload the transmitter.

To make these excellent programs available to guests on his estate Colonel Green has installed on the top of a water tower a group of loud speaking sound projectors connected to another amplifier, the whole being known as a Western Electric public address system. Near the water tower is ample parking space for automobiles and Colonel Green has invited his neighbors to drive in and listen to the programs, which will be clearly audible for a half mile or more. Plans are under way for the installation of additional projectors at Round Hills Light, a rocky isle off the shore of the estate, so that when the New York boat passes in the early evening the passengers may be entertained and farewell messages may be given to departing guests.

With the arrival of its big brother, the 100 watt Western Electric set of Colonel Green's station No. 1 will still render programs, but at less frequent intervals. It will be used to broadcast the work of local artists, and to transmit market and weather reports, local news, etc.

It is fitting that Round Hills should be the home of a great radio station.

In olden days the Master of Round Hills watched his own ships bearing cargoes of all lands to and from the port of New Bedford. Cargoes now arrive at Round Hills House—cargoes of good-will from radio listeners to WMAF's programs. As he reads these letters from lonely farms and frontier camps, from ships at sea, from those isolated by sickness, from his brother radio-



(C. Western Electric)

Colonel E. H. R. Green in his laboratory at Station WMAF.

fans, the Colonel is glad that Round Hills still shares in world-communication. Here, where sky and sea have long played hosts to the Four Winds, has arrived a new guest. Borne on wings of light, yet unseen; unheard, yet bearing tidings to all mankind—radio!

Mexico Generates Our Static— We Get Only the Echo!

THERE is no static in the northern states, and radio fans who think that Dame Nature is not giving them a square deal have a lot to learn. Even heavy electrical showers have little appreciable effect on radio. Such is the opinion of S. Kruse, technical editor of "QST," published by the American Radio Relay League. Mr. Kruse says that the nation's static has its natural element in the Mexican mountains and all the northern states get is the outer fringe.

These views are based on his radio experience of several months in the vicinity of the Gulf of Mexico. "What we get here is very second grade stuff," he says, "but in Mexico they have the real thing and the life of a radio operator on a Gulf steamer, or in a shore station, is well nigh impossible. The static growls and grumbles and raves and pops and at one time the Mexican operators at the old station in Tampico threw their phones on the floor and took to the monte, preferring chances with tigre and the culebra rather than to have their eardrums tortured any more by the tropical radio roar.

"This does not spoil reception for an evening now and then—it blazes away for six months at a stretch and during that time the owner of a radio set had better use it for a rabbit hutch. On a tug-boat off the Mexican coast I have heard static crash and bang so that it was totally impossible to hear any sign of a high-power station less than ten miles away—yet that same station was being heard in Boston at that moment without any trouble.

"A radiophone is simply helpless in that sort of a mess and communication is accomplished entirely with code—radiotelegraph. The Mexican government, the United Fruit Company and the U. S. Navy have strong stations around the Gulf and by using high power and repeating and repeating, they manage to get traffic through. But it certainly is tough on the operators, for they have to unravel a signal from a roaring boiler shop effect that is ten times as loud. At times they have to repeat each word five times, and if it gets extra bad and an important message must go through they repeat each letter as many as ten times.

"Nowhere is profanity so well developed as by these men—the tenth repeat of a message calls for remarks that would make a steamboat mate blush and, if there are many messages on the hook, the sender is likely to be talked clean out before he gets all the traffic cleared.

"Why do they stick? You would not ask if you had ever been in the South—one never likes the North again, one simply swears at the heat and the static and the dumbbell operator at the other end, and the infernal sand fleas and mosquitoes—and sticks.

"Where does the static come from? No one knows. It starts somewhere in the Mexican mountains—the radio compass proves that—but just where or why no one knows. Neither does anyone know why it disappears entirely in the winter and leaves wonderfully perfect conditions to compensate the man that has had the grit to stick. And finally no one knows why there are hours in each day when it lets up suddenly and then crashes out again with full volume.

"All we do know is that it does all of these things."

The Handy Eye-Splice—How to Make it in Hemp Rope and Wire Cable

By Arthur S. Gordon

A NEAT antenna installation is one of the indications of a thorough working radio amateur. On the other hand, if there are frayed rope ends showing, if there are unsightly joints in the wire covered with a mountain of black tape, then it's a ten to one proposition that the radio enthusiast within is neither an ex-boy scout nor a one time sailor. The unseamanlike aspect of his aerial betrays his clumsiness in handling rope and wire. "Oh, what's the use?" ask many amateurs. But they forget that slipshod work in this respect is evidence of careless work in everything they do. The odds are against these amateurs ever getting a set to operate at top notch efficiency.

Splices in a radio antenna, after all, are merely efforts in the direction of maximum efficiency. In making

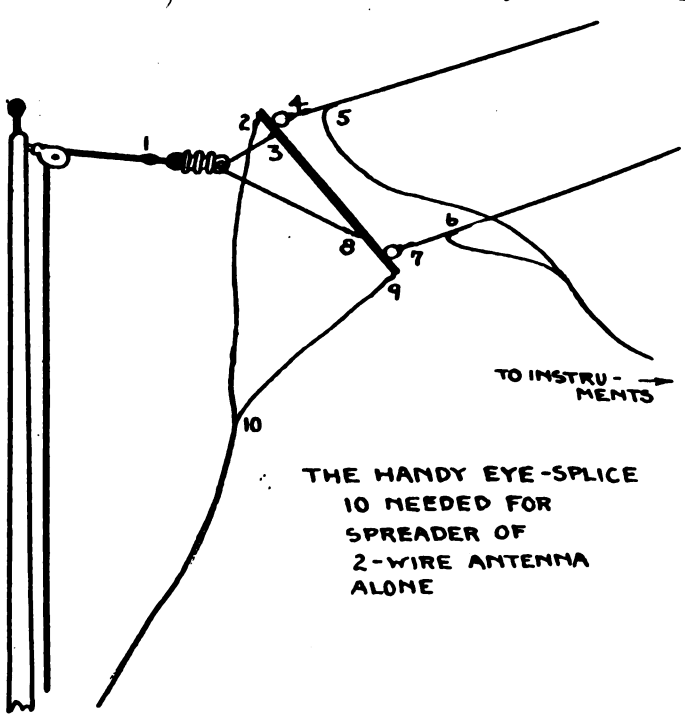

Fig. 1—Showing ten places where the eye-splice can be serviceably used in the erection of a first class antenna.

joints, some amateurs twist the two wires carelessly together and then rely upon the solder they pour over the joint to give them the strength and full electrical contact gained by a more painstaking procedure. In the long run, nothing could be more unsatisfactory. There is no trouble harder to trace than aerial trouble, the sinister part about it being that it shows itself not as a sudden and total breakdown but as a slow, steady deterioration of results. Splice joints, on the other hand, are not only as strong as the unbroken wire, but are electrically perfect. They will never pull out, are the last word in neatness and are especially recommended where the joint cannot be filled with solder, although where that procedure is possible, it is by all means desirable.

Contrary to the general impression, splices are easy to make. Rope, too, is easier to splice than wire, first because it has fewer strands and second because it is workable with the fingers. Boys with whom the author has worked have grasped the principle of splicing in less than five minutes and within ten minutes have been turning out almost perfect specimens of the art.

Perhaps the handiest splice for a radio amateur is the eye-splice, where the end of a rope or wire is turned back upon itself to form a loop or, as it is more properly called, an eye. Refer to Fig. 1. There, in the vicin-

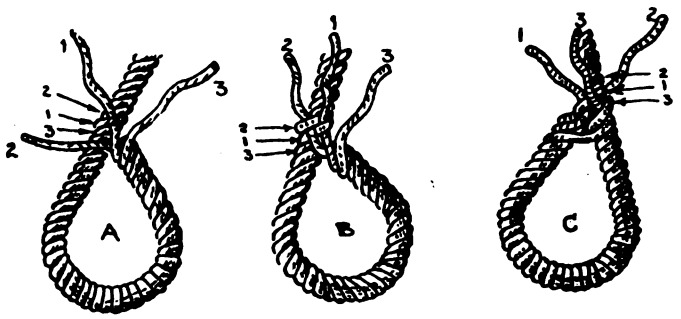

Fig. 2—The three stages of starting an eye-splice in rope. By referring to the text in connection with these sketches it is very easy to splice the toughest rope or the finest line.

ity of an aerial spreader carrying only two wires, are ten places where an eye-splice could be used to advantage. Think of what the ability to splice means to the radio amateur—to you—and then get a piece of three stranded rope and take an immediate lesson, not only in splicing, but also in one of the essentials of proper aerial construction.

Open out the strands for about four inches from the end and bend the rope into a noose with the open strand-ends crossing over the spot in the rope where the splice is to begin. Number the strand-ends 1, 2 and 3, according to the first step as illustrated by A in Fig. 2. Then make the tuck, under any strand of the rope as shown, and the resulting figure ought to resemble in every detail the sketch A. Strand-end No. 2 is the one which comes from behind the other two. It passes over the first tuck and under the next strand as shown by B, Fig. 2. In the meantime, No. 3 has been off on one side. Now turn the noose over, and for a moment, take hold of No. 1 and No. 2 and pull them a little apart. The rope will open, but one strand will remain conspicuously in place. This strand is the one

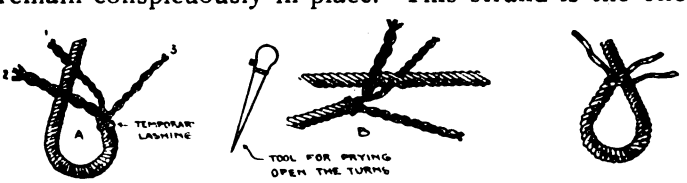

Fig. 3—Method pursued in the splicing of stranded wire. While not as easy as rope, the same method is used. The sharp pointed pricker is used to separate the strands and is a handy tool to work with. The illustration at the extreme right shows the wrong manner of splicing, due to the strand-ends approaching the rope from the wrong direction. Compare it with Fig. 2 A and notice the difference.

under which end No. 3 is tucked. Do not do the obvious thing, which is to tuck it under at once. This will spoil the splice. Instead, take it over the strand, turn around and come back under it, so that strand-end No.

Reflexing the Nite Owl Special

By J. E. Anderson, M.A.

IN RADIO WORLD for July 7 I described the new Nite Owl Special circuit, with which I have had exceptionally good results. Since that article was written I have extended the circuit by making use of the reflex principle, as shown in the accompanying diagram. This circuit gave most gratifying results.

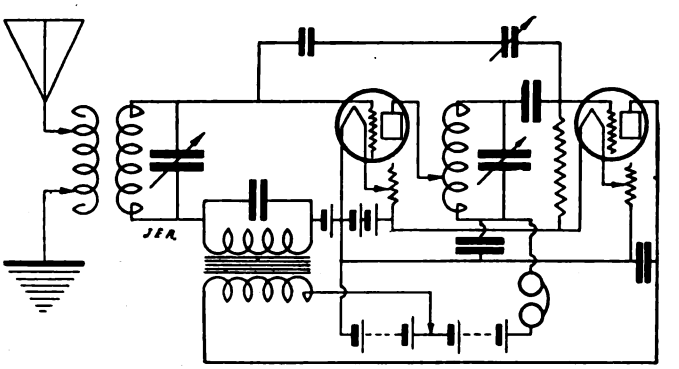
Since the apparent selectivity of a reflex circuit is not as great as the ordinary circuit it was found advisable to use double tuning in the input of the first stage. The antenna is tuned merely by varying the inductance of the coil, which is tapped at every turn. The coupling between the primary and the secondary does not need to be variable unless the added control is desired in a special case. With a little experimenting the best coupling readily may be found. The secondary tuning unit should have a range from 600 meters down to about 150. This is obtained with an inductance of .1 millihenry if the maximum capacity of the variable condenser is 1000 mmfd. and with .2 millihenry if the maximum capacity of the condenser is 500 mmfd. Thirty-two and 44 turns on a 3.5″ tube will give these inductances respectively with sufficient accuracy. The interstage coil should have about 60 turns of wire on a 3.5″ tube and it should be tapped at least every five turns.

The reflex circuit does not oscillate at radio-frequency as readily as an ordinary circuit on account of the resistance introduced into the grid circuit by the audio-frequency transformer. For this reason a larger portion of the interstage inductance coil may be included in the output of the first tube than is possible in the straight circuit described in RADIO WORLD referred to above, and the neutralizing capacity from grid to grid may be dispensed with. However, the circuit will frequently oscillate at an audio-frequency, which gives rise to the familiar howl or squeal. This may be eliminated by reversing the leads to the audio-frequency transformer, or by reducing the filament current, the plate potential or the grid biasing potential.

It is not advisable to increase the regeneration in the first tube to a point where the tube overloads, as this would cause the tube to act as a detector. This, of course, would result in an audio-frequency current in the output of the tube, which would interfere with the output of the tube which is due to reflexing the output of the second tube. These two audio-frequency components of the output of the first tube will usually be out of phase by an amount sufficient to cause considerable distortion in the received signals. For this reason, and the fact that the desired output of this two-tube reflex will be very large, only the larger tubes available on the market should be used.

If it is desired to increase the intensity of the signals beyond the point where the first tubes detects seriously, it should be done by making the detector tube regenerative. This is not shown in the diagram but it may be done by any of the ordinary methods. When this is done it is well to retain the neutralizing capacity from grid to grid to help control regeneration and to prevent re-radiation.

The by-pass condenser in the secondary of the audio-frequency transformer is not necessary as the capacity of the leads is usually sufficient. If it is used it should not be greater than 500 mmfd. A larger value would noticeably by-pass the audio-frequency currents and introduce distortion. The by-pass condenser in the primary of the audio-frequency transformer should be somewhat larger because the self capacity of the leads is much less, and it is necessary to furnish a low impedance path for the radio-frequency currents in the output of the detector, especially if this is regenerative. A suitable value is 1000 mmfd. A larger value than this would introduce a noticeable distortion in the output by shunting the high audio-frequencies from the audio-frequency transformer. If it is desired to tone down the high notes in the output and obtain a softer and more pleasing effect these by-pass condensers may be used for that purpose.



Reflex circuit incorporating the fundamental circuit of the Nite Owl Special. Note the neutralizing capacities which are used to prevent the tube from oscillating.

(*Continued from preceding page*)

3 comes out on the same side of the rope as No. 1. See C, Fig. 1.

The hardest part is over. Turn the noose over again, begin with No. 1 and continue the splicing. Pass over one strand and tuck under the next, always climbing up the rope and not down it. Do this with Nos. 2 and 3 in succession, and watch the splice grow under your fingers. Tuck each strand three or four times, pulling each tuck tightly. Then cut off the ends, roll the splice under the sole of your shoe a few times to smooth it off and the job is finished.

The single caution necessary in continuing the splice is not to mistake the strand-ends for the strands, when working the game of pass one and tuck one. If the rope is very thick, and you want the splice as neat as possible, taper down the strand-ends after the second tuck by tearing away some of the yarn strands.

Can you do it? How about wire, now, with seven strands instead of three? Well, it is just as easy. The soft wire used for aerial is very easy to handle, and the only tool needed is a miniature marlinspike, or what sailors would call a steel-pointed pricker. This may be any pointed piece of iron or steel, about the size of a leg on tinsmiths' pocket dividers. Unlay the wire as you did the rope and temporarily bind the throat with string, as shown in A of Fig. 3. Now twist the seven strand-ends into three and proceed exactly the same as with rope, with the small difference that you tuck under two strands instead of only one. When continuing the splices, pass over two and tuck two.

Eye splices are also used when joining a rope or wire end to the middle of another rope or wire. See B, Fig. 3. This is done when tapping off the lead-in wires.

Station NAA Gets a New Voice

By Carl H. Butman

WASHINGTON, D. C.—Sea-going radio operators, many skippers and landsmen who listen in will note a change in the "voice" of NAA at Arlington 2,650 meters. The peculiar tone of the old Fessenden spark will no longer carry the time signals, weather reports and information of great interest to mariners. This famous spark set installed in December, 1912, was replaced on Sunday, July 8, by a new tube transmitter.

Operating on the same wave length, 2,650 meters, the new set will carry all the governmental broadcasting formerly done on the spark. Although its power is not quite as great, the range of the tube set by tests has proven a little greater than the old 100 KW spark. After eleven years of almost constant operation, the Fessenden set is to be retired from active service, and it is understood that it may be presented to the National Museum, where many radio experts believe it should have the honor accorded to the early locomotive of Baldwin and the Morse telegraph key.

Even before its installation in 1912 as the first high powered radio transmitting set in the United States, the Fessenden set was used in test work for nearly two years between the Plymouth, Mass., radio station and the Mackaranish station in Scotland by the Fessenden Company. A service of almost thirteen years is believed to be a record for even a modern radio set.

Besides the seafaring radio operators, many ship masters will miss the tone of the Fessenden spark. Careful skippers, it is said, check their chronometers personally in the radio shack when NAA broadcasts time twice each day. Trusting their operators in everything else, they prefer to put on the receivers themselves and count the dashes preceding the time signals at noon and ten p. m. noting the number of seconds fast or slow when the hour is designated by the long dash. Masters on the Atlantic and Mediterranean runs whose daily progress is noted in degrees of longitude, rely almost solely upon the time by radio, especially when the sun is not visible, and never miss an opportunity to check their ships' clocks.

In the old days before radio time transmission, east and west navigation was a more difficult task, since the mariners had no means of calibrating their time pieces while on a cruise requiring from ten days to two weeks. An accurate record of the chronometer's gain or loss in time per day had to be kept, and every observation had to carry the correction multiplied by the number of days out of port. This of necessity increased any unknown error and made navigation far from the accurate science it has become with the advent of radio time. Once in port, the master carried his chronometer carefully ashore to a reliable clock maker or watch expert and had it checked. The result was a correction in gain or loss in seconds per day and, as has been explained, necessitated daily corrections for exact time. Today there is no reason for the skipper to carry his timepiece ashore for calibration, except about once a year, since he can correct it twice a day no matter where his ship is.

While the time is sent from NAA primarily for Naval vessels, it is extended as a free service to all who sail the seas, besides all who listen in ashore. The new set will, it is believed, improve the time signals somewhat in audibility and in range.

State College to Teach Radio by Correspondence

CORRESPONDENCE courses in radio reception and transmission are now being offered by the Engineering Extension Department of Pennsylvania State College. According to N. C. Miller, head of the department, this new bit of extension service has been instituted in response to a large number of requests that have been received.

The course is divided into two parts, each with its own text and assignment pamphlets. The first part establishes principles and suffices for the ordinary student. It takes up common electrical phenomena, radio circuits, the vacuum tube, amplification, sources of power, transmission circuits, and applications of radio.

The second part is a continuation for those desiring advanced instruction and goes more thoroughly into the theory of electricity in order to prepare for a detailed study of electromagnetic waves, radio circuits, and apparatus for reception and transmission.

The purpose of the course is to correct the impression of mystery which surrounds radio and to show that the fundamentals of radio are not as mysterious as is commonly supposed. At the beginning it is assumed that the student has no knowledge of radio and very little of electricity, and the course is developed on that basis. Mathematics has been reduced to a few simple calculations and all technical terms are explained clearly.

"Despite the wide use of apparatus of all degrees of complication, there is still very little known by the average layman of the underlying principles of radio," says Professor Miller. "As a result much apparatus is installed without regard to anything but a blue print of a hook-up which as often as not does not give the maximum service for the outlay of time and money. In many cases the radio fan connects up apparatus at random, hoping by luck to strike on some scheme that will give him desired results. This is often fatal to valuable tubes and apparatus." Inquiries concerning the course should be sent to the Engineering Extension Department, State College, Pa.

Tuning Tips

IN order to get the maximum results out of any receiver the set should be retuned after a station is found. This allows all the circuits to be tuned in resonance. The primary circuit is the governing feature of any set and should be tuned carefully, after which the various other controls are tuned.

"Original Radio Girl" in Her Own Studio

VAUGHN DE LEATH, so popular with radio fans through her frequent appearances before the microphone, is about to challenge the approval of radio audiences in a new role—that of studio and program manager of station WDT, New York City, now on the eve of opening for general broadcasting.

Rated among the leading women composers of the country, her songs and musical scores are known to all lovers of good music. As a recording artist, her phonographic records have had an enormous circulation, marked by an unusually even distribution over the entire country due, no doubt in a large measure, to the great range of her contralto voice (three octaves) and its quality of sympathetic appeal.

This young woman's remarkable versatility is further shown by her high rank as a piano player (not the mechanical kind) and by her success as director of her own band and orchestra of more than sixty pieces, as well as by her popularity as a concert singer and recitalist.

Miss De Leath was the first woman in the United States, and hence in the world, to broadcast vocal music for the benefit of the general public, with whom she has proved a decided favorite. She was the woman chosen for the first successful attempt to bridge the Atlantic by a woman's voice. It is for these reasons that she is so widely known as the "Original Radio Girl."

The radio-loving-public will now have an opportunity to observe her versatile talent further exercised for their benefit in the direction and management of her own broadcasting studio.

Miss Vaughn DeLeath, the "Original Radio Girl," is now manager of the studio at Station WDT.

The Radio Woman

A YOUNG lady who had recently acquired the bad habit of repeating things she had heard, was surprised to find out that she couldn't get any thrill out of telling her friends about the news she heard by radio, because they all read RADIO WORLD and kept up to the second on all the latest radio gossip and news. Then she turned around and sent in her subscription for RADIO WORLD and now keeps up to the minute on everything without having to worry that she will lose or miss anything.

* * *

It is one of the greatest of marvels to me what a wonderful influence a violin solo has on some people's nerves. I have a very good friend who drops in occasionally to see me and is one of the most nervous women that I think I have ever met. She simply cannot sit still. She must be moving all the time. She visited me one day last week and after watching her show her case of nerves, I suggested that we listen to the radio. As luck would have it, there happened to be a wonderful violinist on at the time and my friend just sat and listened right through, closing her eyes and not even moving. When it was all through, she remarked that it was wonderful. "If I didn't know that it was coming through that phonograph horn (my loud speaker) I would have thought that he was right here in the room. I love violin music—it seems to act like a soothing drug to me. I really believe that were he to play long enough he could put me right to sleep in a crowded train."

* * *

I think Friend Husband has bought more classical records since we have had our radio than he ever bought in his whole life before. He would hear a piece sung, or played, and if it appealed to him (and nearly every orchestral rendition of some famous suite was sure to) bright and early next evening, along would come hubby with two or three expensive records with that particular piece on. I don't think that we have bought more than a half dozen of those comical records since then, though before we used to specialize on them. How much nicer it is to hear Beethoven's "Moonlight Sonata" played by the Philharmonic Society Orchestra, than to hear "Yes, we have no oranges" by some comedian, that we will get tired of in no time.

Washington Signal Laboratory to Reopen

MAJOR J. O. Maubourge, Signal Corps, who was recently placed in charge of the Signal Corps laboratory at the Bureau of Standards, expects that experiments will start there on July 25th. Among the early experiments planned is the development of suitable terminal apparatus for transmitting General Squier's new universal alphabet. Since this code alphabet is intended to increase the speed of automatic transmission in cable, wire and wireless dispatches, the development of the necessary transmitting and receiving apparatus is necessarily somewhat complicated. With its perfection, it is understood that the Army Message Center located in the Munitions Building will then conduct some long-distance speed transmission tests, as soon as the apparatus can be installed there and at a distant station.

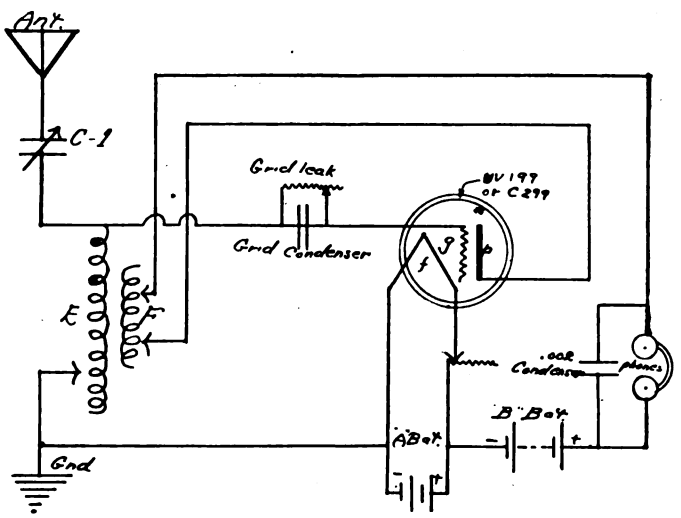
A Good U.V. 199 Hook-up

By C. White, Consulting Engineer

A FRIEND of mine recently said "circuits may come and circuits may go, but the single circuit regenerative is here to stay." Of course, the subject can be nobly argued pro and con but you have to admit that a circuit which would give more volume for a single tube than the single circuit regenerative circuit would have to go some. Then again, the circuit is very inexpensive to build and is almost fool-proof in operation. It is the utmost simplicity combined with the utmost reliability. I do not wish to go on record as saying that it is the best, for it is not, but I will say that for the amount of money invested and the results produced it is and will be for quite a time a leader. It can be constructed to be very compact and, while it is generally considered as a receiver with a radius of 500 miles maximum, it has been known to reach out as far as 2,000 or even more in cool weather. By using



A single circuit regenerative especially adapted to the new U.V.199. Note the fact that the tickler inductance is variable, which adds considerably to the ease in obtaining the critical regenerative point just before the tube "spills."

the new UV199 tube and dry cells throughout the maintainence expense is very small and quite negligible in comparison to that of more expensive outfits.

The circuit illustrated in the diagram herewith has been simplified to the greatest extent. No unnecessary controls have been included and the use of expensive variometers and variocouplers has been avoided. The tuning element E is wound with No. 22 D. C. C. magnet wire on a four-inch tube. This coil should have 60 turns in all with a tap at every 15. The coil F fits inside of the coil E and is therefore wound on either three or three-and-a-half inch tubing having 60 turns in all but differently tapped for switch points. One switch arm should allow connection to every 10 turns while the other arm should provide a fine adjustment allowing a tap-off at every turn. This means that the first 10 turns should be tapped by one switch for every turn in that 10 while the other switch arm should only tap off the entire coil in units of 10 turns. A similar arrangement is resorted to on certain variocouplers to obtain a fine and a coarse adjustment of the number of turns. The coil E is the main tuning inductance and the coil F is the tickler or regeneration control coil. Two switch arms control the number of turns of wire active on F while one such arm controls the number of turns in use on the coil E. The coils E and F should be wound with a piece of string between the turns in order to keep each turn from touching the next. By so winding the amount of distributed capacity of the coils is cut down. Very often a single circuit receiver is accused of being broad, but generally such trouble arises from the fact that there is a lot of capacity between turns of the inductance coil and the condenser employed has been of poor construction. Laboratory tests have definitely proven that a large number of condensers really act more like resistors in the circuit than condensers. Poor insulation and faulty construction are to be blamed. It is of the utmost importance to keep capacity out of a coil and resistance out of a condenser. I have constructed single circuit receivers bearing these facts in mind and have obtained very good selectivity—in fact, better selectivity than is possible with many double or triple circuit affairs that use poor parts.

I wish to call particular attention to the fact that the better the set is made the more important it will become to have a vernier condenser attachment on the condenser C-1, which is an 11 or 13 plate air variable. A 30 ohms rheostat must be used with the new tube in order to get a fine variation of filament current such as is necessary to control the detection. Failure of the tube to oscillate may be due to the fact that the terminal connection to the switch arms of the coil F should be reversed. A proper type of grid leak and grid leak condenser will play an important part in the successful operation of the outfit. A good variable grid leak would be a desirable asset to the outfit, as well as a good mica grid condenser. Do not forget to see that the movable plates of the condenser C-1 are connected up to the antenna and the fixed plates to the grid side of the circuit. By so doing you will avoid quite a bit of grid howl and body capacity effect when tuning in your set.

Ain't it a Grand and Glorious Feelin'?

WHEN you get the new set home, attach the aerial and ground, put on the batteries, plug in the phones, turn on the juice, turn the dials and hear nothing? Your heart stops beating for a five second space, you look at your connections, wiggle your jack and plug, look at your phones, look at your tubes and they seem all right. You know that something is wrong, but can't figure it out. It must work!

You try to remember if anybody ran into you while you were carrying it—and faintly remember a fat man bumped your arm on the car. Hurriedly you examine the connections only to find that everything is perfectly O. K.

Suddenly—a bright idea—you look at your B battery and find there is a loose connection.

OH, BOY—ain't it a grand and glorious feelin'?

The Reasons for Trouble

THE average fan, when he first starts up of course reads loads of books on radio, and after hearing a million and one "Don'ts and Do's," is quite likely to question the validity of more than nine-tenths of them, because he does not see any direct bearing or reason for them.

He does not realize that experience is a wise but expensive teacher, and more than once is taught himself by his own experience just because he did not take the advice of others who have tried things and found out.

He will often boast that he receives long distances on a set that "hasn't a single soldered connection" not realizing that if he had soldered them he would have reached further. He thinks that soldering is a "bunch of bunk" and is simply specified because some fellow wants to make him work. Did he ever see a naval or professional set that "wasn't soldered"?

He burns his tube up as bright as he can without absolutely ruining the signals by distortion. The makers of the tubes may specify that a certain voltage should be used on the plate when it is used as a detector, but he puts on double the amount and thinks that he has "put one over" on the manufacturer.

He purchases a wonderful set, or makes one, and then puts up a poor antenna and to balance the bargain he connects the set to an equally poor ground and wonders why his set doesn't get the good results that are claimed for it.

He reads about some hook-up that "looks good." He makes it up and skimps on the expense by buying cheap parts, rushing the construction and then kicks when it doesn't turn out to specifications.

People wouldn't waste their time writing and experimenting and prescribing "Do and Don'ts" if there was no reason for it.

Think it over the next time your set doesn't satisfy you and see which of the ten and ninety commandments and rules you have violated.

Arc Transmitters Create Interference

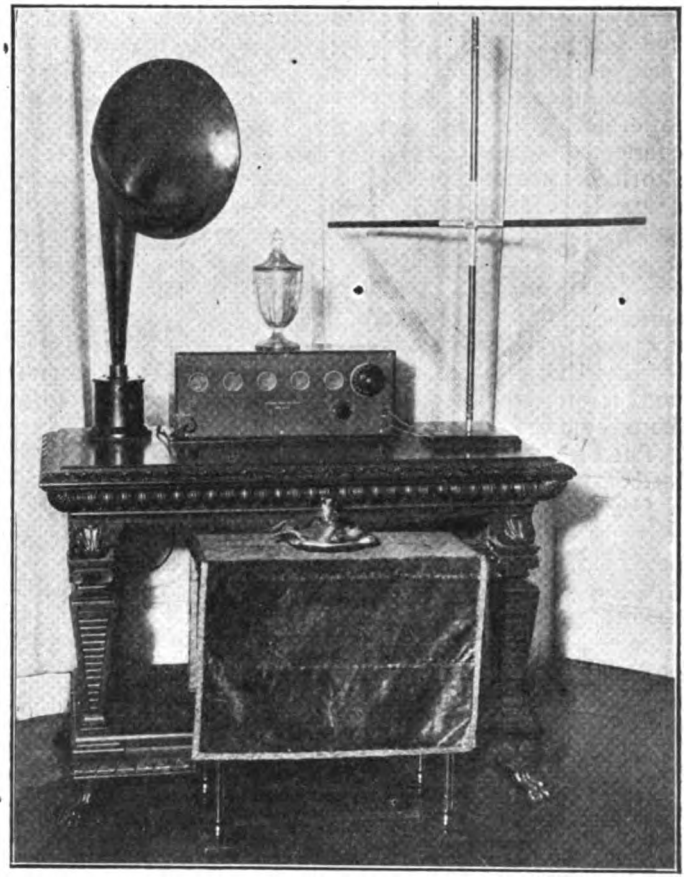
RECENT reports from the Navy Department indicate a very considerable amount of interference from mush and harmonics at all points within 200 miles of Pearl Harbor. Current transformer circuits will be installed on the Honolulu transmitters of the Navy within the near future, which will eliminate this interference it is hoped.

Naval experts admit that arcs and spark transmitters create a considerable amount of interference in their vicinity, unless special circuits are installed to reduce such interference. Transmitters of these types are being modified as rapidly as funds permit. On arc transmitters current transformer or similar circuits are being installed and spark transmitters are being replaced by tubes. Owing to the large number of transmitters operated by the Navy and the limited funds available, this work is, of necessity, proceeding slowly, but it is expected that the greater part of this interference will be eliminated during the next fiscal year.

Radio as An Ornament in the Home

YOU fans who take delight in showing pictures of sets with a dozen controls and a rheostat for every tube, take a look at the illustration below, which is the radio installation in the home of Dr. Donald M. Gildersleeve, 169 Prospect Park West, Brooklyn, New York. It is a five tube radio-frequency set using a loop antenna. The tuning is all accomplished by means of the condenser located at the right hand side of the set, and by swinging the loop in the direction of the desired station.

The set is conveniently located in the living room



An arrangement such as this makes a radio set an object of beauty as well as of service in the home.

of Dr. Gildersleeve's home, and will bring in long distance on a loud speaker such as is shown in the picture. The loud speaking unit is a Western Electric D10, and the set is a Davidson 2-R-S. It makes a handsome appearance, and we are told that it does some very neat work.

This receiving arrangement recently was entered for a prize that was to be awarded to the owner of the neatest receiving station, and it seems to deserve it, because it most surely is an artistic as well as utilitarian installation.

One Way of Doing It

If capacity effect is noticed when the antenna condenser is tuned, reverse your condenser leads. Where **a condenser is used in the ground** the rotary plates should be connected to the ground.

RADIO PRIMER

By Lynn Brooks

WIRING THE RECEIVER: Some amateur builders of radio apparatus will spend hours drilling, tapping and finishing the panel and cabinet of a receiver and when that is all done will wire the set with any kind of wire they happen to have at hand, not caring whether half of it is wired with bus bar and the other half with flexible leads or anything that may be handy.

In the wiring of a set it must be taken into consideration that the leads should be as short as possible to make them, and they should have as little resistance as possible.

Another point that is important, but neglected, is the bunching of leads. Wherever possible, the leads on a receiver should not be bunched or connected together in a manner that will tend to bring several leads close together. Just because the diagram specifies that a connector goes from the plate to the phones and another from the plate to the antenna side of the inductance and there is still a third that goes from the plate to the plate battery side of the phones, is no indication that all the leads should run directly to the plate connecting screw of the socket. It is often possible to eliminate several inches of wire by simply connecting one wire in such a manner that all the other leads that tap off on it can easily be bridged by a single wire from one of the other leads, and thereby eliminate bringing more than one lead to any connector.

The insulation of the leads is also important. Where leads cross even, though not real close, it is best to slip a few inches of spaghetti or some other insulating material across them. Do not run leads parallel for any length.

When placing the apparatus on the panel, consider before you drill the panel, the way in which the apparatus will control the wiring scheme. You can ofttimes by simply placing the condenser or coupler to the other side of some particular piece of apparatus eliminate a long lead.

Where leads are to be connected to some movable apparatus it is best to use flexible leads and fasten them to the solid wire. This gives freedom of manipulation and eliminates all chances of broken leads in after time.

FINISHING THE PANEL: In the final appearance of a set, the shiny panel does not generally look as rich as the finished satiny sheen of a manufactured set. It is very easy to give that satin finish to a panel if a little care is taken in the work.

Before the apparatus is mounted, take a piece of No. 0 sandpaper and carefully rub the panel lengthwise, being careful to do this in long, straight strokes, working from end to end. Do this until the entire panel is dull and scratchy looking. Do not make the mistake of rubbing with a circular motion, but keep even with each edge of the panel. Then brush off the dust, get some fine steel wool, and repeat the process until the panel has a dull, smooth finish. Then soak the steel wool in light machine oil, or melted vaseline, and continue to rub it. After the entire panel has been rubbed, go over it again with a clean cloth on which is some more oil or vaseline, and finally rub the whole thing down with a clean cloth, taking all the excess oil off. The panel will now be found to have a nice dull satin finish, but if a higher finish is wanted, get some rotten stone and put it on a rag dry, and repeat the process above until it has a real high finish, always taking extreme care to rub the panel in one direction only, whether using the sandpaper or the rotten stone.

RADIOGRAMS

With the 2 k.w. arc and chopper installed on the S.S. "Eastern Glade" reliable night communication was accomplished on 600 meters from Durban, South Africa, to Madagascar for a period of over a month. The distance between the above mentioned places is approximately 1,200 miles.

* * *

Extension of the market news service of the United States Department of Agriculture, involving the establishment of one of the largest commercial leased telegraph wire and radio systems in the world, has been announced by the Department of Agriculture effective as of July 1.

* * *

The authorities of Westchester County, N. Y., last week sent out a general alarm for a negro wanted as a suspect in the murder of Dorothy Kauffman, a governess at the home of Magruder Craighead in Greenburgh, and had his description broadcast by radio from Station WRW at Tarrytown, N. Y.

* * *

The marriage is announced of Miss Jessie E. Koewing to Carlton Brown. Miss Koewing is known to thousands of radio fans, her pleasant voice having been employed at the WOR broadcasting station, Newark, N. J. Mrs. Carlton Brown has resigned from her activities with L. Bamberger & Co., who operate WOR.

* * *

An automobile was stolen from a motor company in Kansas and a few hours later news of the robbery was broadcast. In ten minutes a long-distance call from a farmer told the motor car dealer that a car answering the description he had picked from the ether had been abandoned in a ditch and a neighboring farmer had the car in his yard.

* * *

With the Model TF tube transmitter installed on the U. S. Cruiser "Omaha" reliable communication was obtained up to 1,200 miles by day on CW and up to 1,600 miles by night on ICW and voice. With the 20 k.w. arc daylight ranges of 1,800 miles were obtained while working vessels of the U. S. Fleet, and 2,000 miles while working shore stations.

* * *

Arthur Hammerstein is strong for the broadcasting of his musical shows. It is invaluable advertising, he thinks; but not so with the dispensing of his airs through the orchestras of the cabarets and hotels. He has instituted injunction proceedings against the band leaders of London to restrain them from playing the various tunes of "Wildflower."

* * *

Station WMAK, Lockport, N. Y., will discontinue broadcasting during July and August, except the weather and farm reports, which will be sent out on the 360-meter wave length at 11 A. M., Eastern Standard time. The station will be remodeled and alterations made in the transmitter during the summer. It will operate as a Class B station in September.

* * *

A daily radio service, direct from New York City markets, giving last-minute prices on farm commodities, has been inaugurated by the *American Agriculturist,* a farm journal, in co-operation with the Department of Farms and Markets and Station WEAF. The service will start at once and be given every Tuesday, Wednesday, Thursday and Friday at 10.50 a. m., Eastern Standard Time.

* * *

The Naval Radio Traffic Station at Cape May, N. J., has been closed and abandoned. The transmitter at that station was removed to the Radio Compass Station at Henlopen, the latter station becoming the compass control station for the group composed of Cape May, Cape Henlopen and Bethany Beach. Traffic formerly handled by the Cape May station will be handled by the radio station at Philadelphia.

* * *

Few American cities are so completely wired for electricity that they can provide their push-cart men and their sidewalk merchants with electric lights to hang over their stands at night. Japan does, and is rapidly approaching American universal and highly specialized use of electrical energy in her homes, factories and shops, according to a bulletin of the New York State Committee on Public Utility Information.

* * *

Dr. Louis Bell, the eminent electrical engineer, whose recent death was chronicled in Radio World, had a profound knowledge of wireless telephony among his many remarkable achievements. During the World War he was a member of the advisory committee of the Council of National Defense, and, with Norman Marshall, of Waltham, Mass., invented a system of signaling by ultra-violet rays which enabled dots and dashes to be transmitted invisibly to the enemy, but with accurate reception for several miles by troops provided with the proper apparatus.

Amateur Radio Station as Powerful and Complete as a Commercial Plant

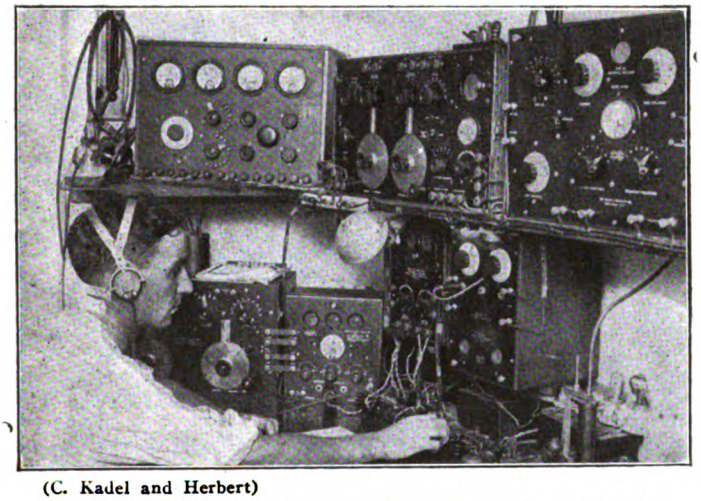
By Lynwood Cowen

CONSIDERING the tremendous strides made by amateurs throughout the United States during the past year, it is not surprising that some very fine and complete sets and stations have been established.

Heretofore all amateur stations have as a rule kept strictly to amateur practice, but it remained for Walker P. Inman, a New York amateur and owner and operator of station 2BGM to establish a station that is far away and above anything else in that line.

To illustrate this fact, take a look at the transmitter which is used for phone work. It uses four 250 watt tubes with an input of 1,000 watts. The antenna radiation is six amperes and, with this transmitter, Mr. Inman has reached Honolulu and many other points as far away.

The receiving side of the station is a most complete one, and the number of receiving sets would make an operator on a ship turn green with envy. There are three sets used, one a navy receiver with a range of from 300 to 8,000 meters. This is mostly for commercial work, as it is on these wave lengths that the receiver is most efficient. A Universal receiver with a range of from 150 to 25,000 meters is also used both for short and long wave work. A radio compass receiver for use with a loop is also used. Any one of these sets can be used simply by plugging them in the circuit, and if desired from one to four stages of amplification can be employed. The illustration shows the sets. There is also a 20 watt transmitter used when communication by CW and ICW is desired. This is shown on the upper shelf in the left hand corner.



(C. Kadel and Herbert)

Receiving equipment at Station 2BGM with the owner operating. The 20 watt CW transmitter is located on the upper left hand shelf. The compass receiver with three-stage amplifier is located directly under it on the table while the naval receiver and universal receiver are directly over the two-stage amplifiers directly in front of the operator.

(C. Kadel and Herbert)

Powerful 1000 watt transmitter used at Station 2BGM for broadcast work. Walker P. Inman is shown inspecting one of the 250 watt tubes. This transmitter is of the exact type used in commercial stations and current for the operation of the set is derived from a special generator set. With this set six amperes can be put into the antenna.

Handy Equipment

MANY times when an amateur is building a set, or considering the construction of one, he wonders just what tools are necessary, or maybe he has some few tools, and could do better if he had more. It does not require many tools if you intend building a set from parts that you purchase, but the list given below will help the average fan in making his set:

One breast drill; one set of drills for above in 16ths from 1/8 to 9/16ths; a try square—12-inch blade; 1 good steel punch; 1 hacksaw and set of blades; 1 soldering copper; 1 compass; 2 screwdrivers—1 12-inch and 1 four-inch; 1 pair of electricians sharp nosed pliers; 1 pair of side cutting pliers; 1 small vise; a sharp knife; 1 table clamp.

Station WCAP Opens

WCAP—note the initials—the new Washington station of the Chesapeake and Potomac Telephone Company, opened on July 4 by broadcasting a duplicate of the New York Telephone Station, WEAF, program carried by land lines to Washington. This simultaneous broadcasting in two cities was very successful, except for a slight hum due, it is believed, to the long land line from New York to Washington. Operating under a temporary license, it is understood that WCAP will continue to broadcast the New York program occasionally until arrangements for the local program are completed. The station is licensed in Class B on 469 meters and has a power of 500 watts. It is Washington's first B station, although Arlington, NAA, is actually in this class.

The Beautiful, the Practical and the

(C. Photonews)

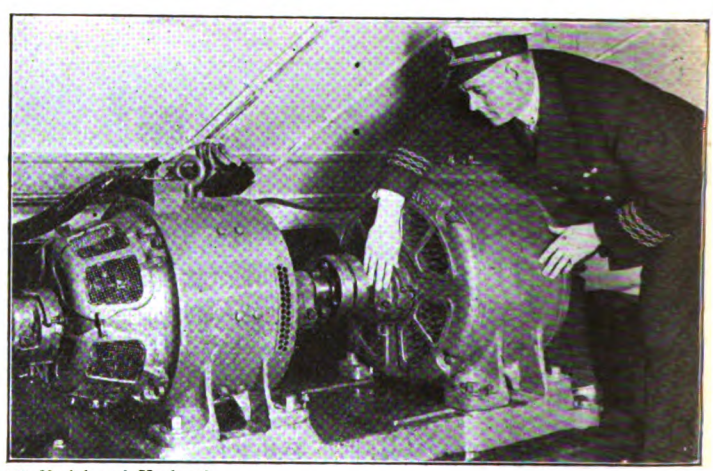
"Mother, may I go in to swim?" "Yes, my darling daughter. Take your radio set along, and sit right near the water!" That's the way we would sing the ancient ditty, after seeing Sara Mullen enjoying a sun bath at Rye Beach, New York, with the aid of the new portable Radiola which operates on dry cell tubes with neither antenna nor ground.

Captions by Robert L. Dougherty

(C. Kadel and Herbert)

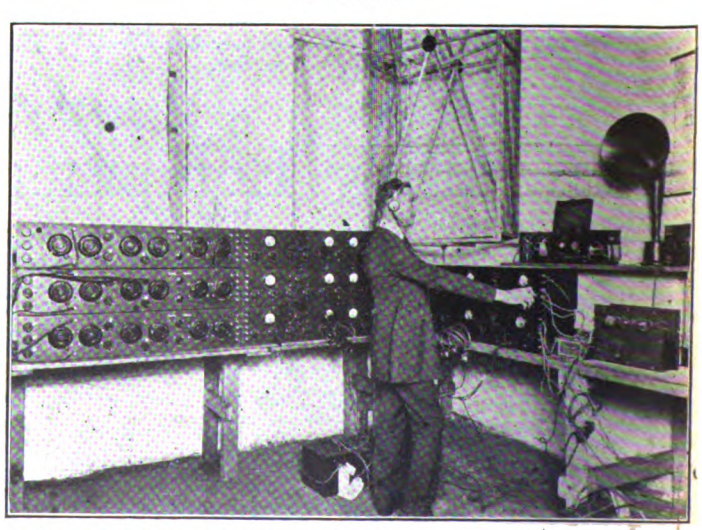
Automatic radio is being installed in Parisian cafes, hotels, and other public places. The idea is proving quite popular with those who do not own sets. Regular time schedules are kept by the broadcasters, and by simply removing the phones from the hook and listening at the right time a full-fledged radio concert may be had without the necessity of tuning in.

Station WLW, of the Crosley Manufacturing Co., Cincinnati, recently gave a series of swimming lessons by radio. The lessons were broadcast by Stanley Brauninger of the Y. M. C. A. from the station, and by means of a portable set with loud speaker children were instructed in the natatorial art. This is the first time anything of the kind has been attempted, but the fact that it met with success shows to what lengths radio instruction can be utilized.



(C. Kadel and Herbert)

Chief Radio Officer Pickerell of the S. S. "Leviathan" inspecting the motor-generator set of the world's largest ship after using the set for tuning and testing. This generator set is the largest installed on any commercial vessel for the purpose of communication. The power furnished by this plant is enough to light a good sized town, but instead of doing that it is used to furnish power to keep this floating city in touch with both continents during its voyages.



A laboratory equipment that would make the average fan's envy mount to the skies. Five ten-tube super-heterodyne receivers all blasting at the same time bringing in five distant stations. This experiment was recently carried out by the Experimenters' Information Service in New York City in order to determine the amount of interference that had to be overcome by the use of antennae that were centrally located, and the amount of interference that could be overcome by the use of specially designed loops.

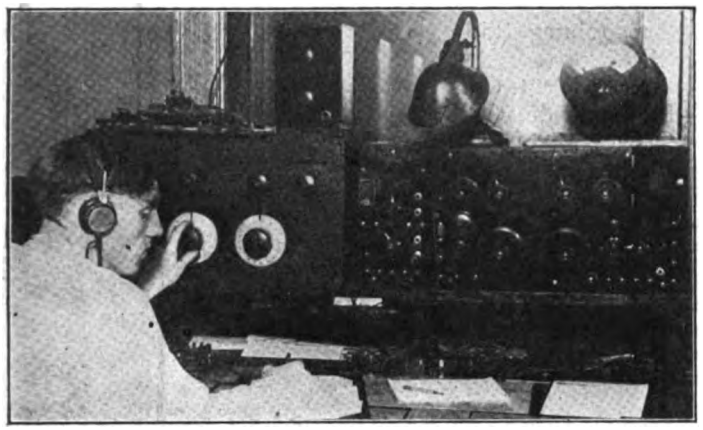
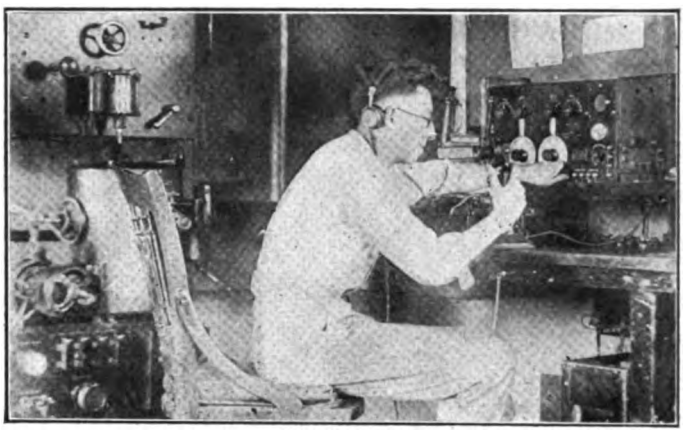
e Scientific Phases of Radio News



(C. Photonews)

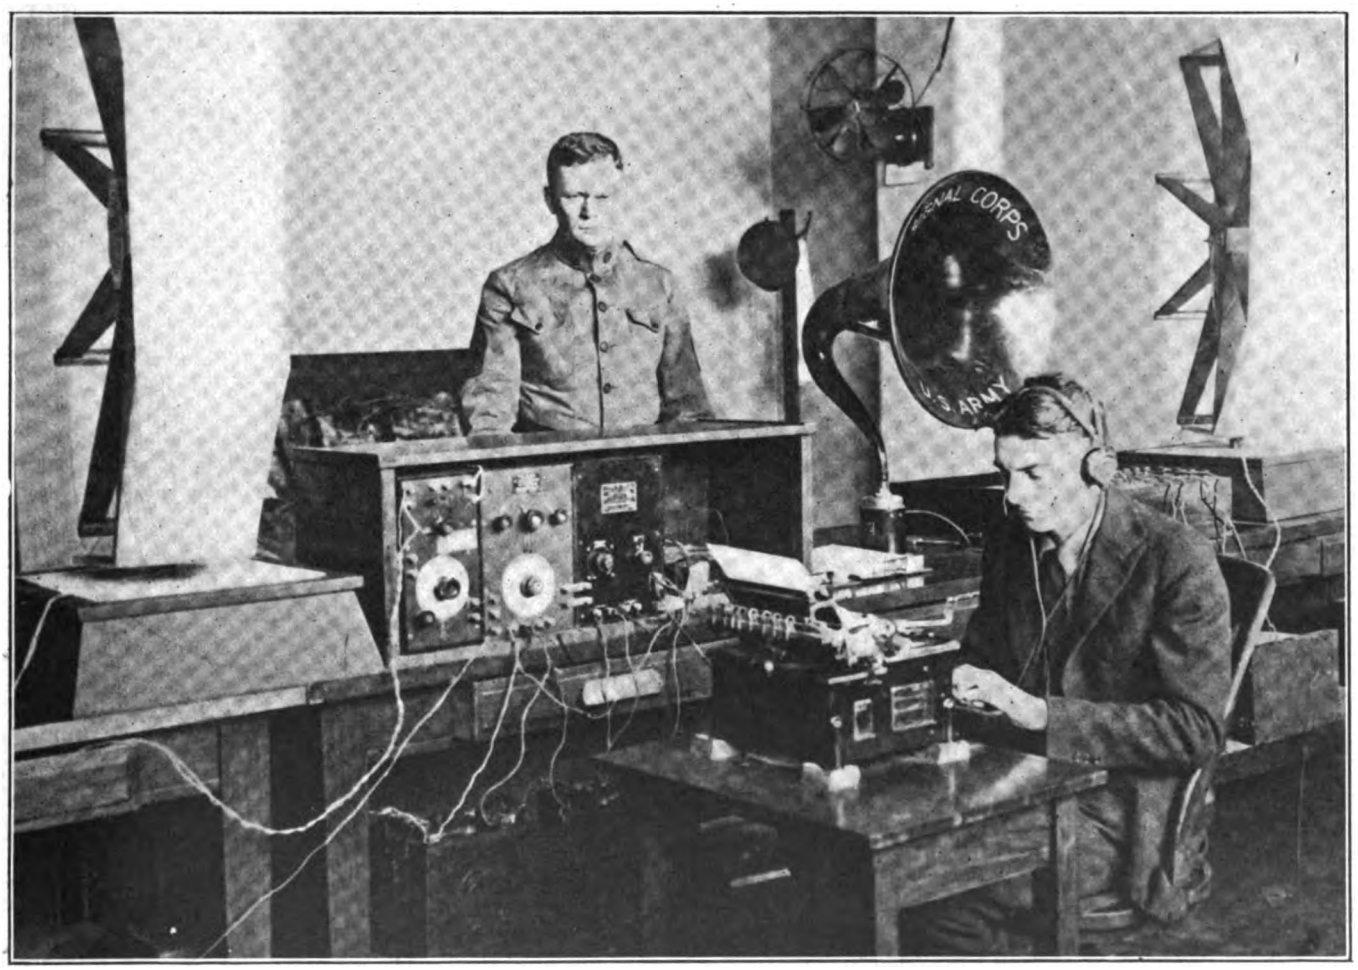
Here is the station that many amateurs and broadcast listeners hear just when their sets are bringing in the DX. It is the spark station WNY, at Bush Terminal, Brooklyn, N. Y. The illustration shows Ernest Engelder, chief operator, using the heterodyne receiver.



(C. Fotograms)

The Air Mail Radio Station of the Post Office Department, located at Garden City, L. I., which keeps in touch with the 'planes and landing fields all over the country. It is by means of this station that the service can be kept in touch with all delays and maintain the air mail service at its highest efficiency.

U. S. Signal Corps Uses Loops to Receive European Stations in Washington, D. C.



(C. Fotograms)

The U. S. Signal Corps' radio station at Washington, D. C., does all long-distance receiving of European and foreign stations by means of loops and heterodyne receivers. This eliminates the necessity for long antennae and large inductances, as the loops are wound with the necessary amount of wire to allow reception over ranges of 15,000 to 30,000 meters, and tuning is done by means of the condensers across them. It is in the laboratory of the U. S. Signal Corps that Brig. Gen. Squier, Chief Signal Officer, conducts all his experimental work, and where the wired wireless system was perfected.

Peak in Broadcasting Stations Reached

By Washington R. Service

WASHINGTON, D. C.—Broadcasting is apparently slowing down slightly, based upon the number of stations in operation today. The peak of the curve of this popular service was reached in May, when 591 stations were on the lists of the Department of Commerce. On June 30th, there were 573—18 less stations than in May, although there were 115 more than in June, 1922.

The broadcasting service which started in September, 1921, with three stations, rose slowly during the last months of 1921 to 28 at the end of the year, but in March, 1922, it began to climb by leaps and bounds, reaching 576 in December, 1922. January showed a loss of six stations but this was made up in February when a total of 581 was reached. Following the National Radio Conference in February, 1923, this figure increased until the peak of 591 was reached in May. With the allocation of wave lengths, a number of stations have dropped by the wayside; fifty stations were deleted in June, more than in any other month since the service was undertaken.

On June 30, the total of 573 stations was distributed as follows: Class A, 203; Class B, 42; Class C, 327; and Class D (development) 1.

During the month of June, 31 new Class A stations were licensed and one Class B. 27 C's were transferred to Class A, and two were granted Class B licenses. In June, one Class A station stopped broadcasting, and 49 Class C's, on 360 meters were deleted.

The stations dropped from the records of the Department during June follow:

One Class "A"

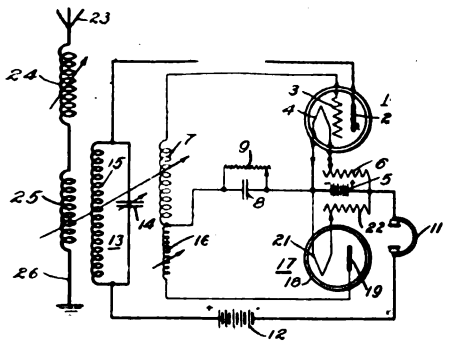
Latest Radio Patents

Wireless Receiving System

No. 1,455,768: Patented May 15, 1923. Patentee: J. Slepian, Swissvale, Pa.

This invention relates to methods and means for amplifying currents and particularly to wireless receiving systems.

In its broad aspect, the object of my invention is to provide an improved



Receiving system utilizing cascade detection and selective feedback.

wireless receiving system which has highly desirable operating characteristics and which is responsive to signal impulses radiated from either damped or undamped wireless transmission systems without the customary heterodyning step.

More specifically, one object of my invention is to provide a receiving system which admits of an extremely high amplification of received signal impulses.

These and other objects of my invention will be apparent from the following description of the nature, the mode of operation and the advantages of my invention.

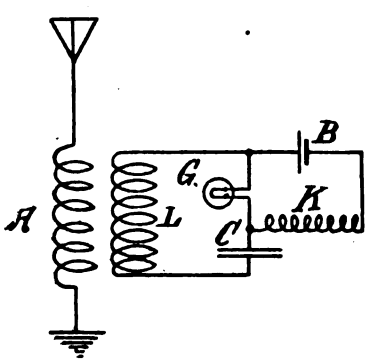
It is well known that, in a regenerative feed-back system employing a grid condenser having insufficient grid leak, the system oscillates intermittently, as indicated by a howling in the telephone receivers. That is to say, upon some slight unbalancing of the system, the tube is set to oscillating, the oscillations increasing in amplitude. When the amplitude of the oscillations stops increasing, the oscillations become unstable since any slight decrease in their amplitude fails to produce a corresponding decrease in the charge in the grid condenser; hence the oscillations continue to decrease in amplitude and finally stop. When the charge on the grid condenser has decreased to a sufficiently low value, as determined by the constants of the system, the oscillations again build up, as before, and the blocking action is repeated. It will be noted that the oscillations must build up to approximately the maximum limits of the tube before the blocking action becomes effective.

I have found that, by increasing the charge on the grid to values higher than the peak value of the alternating grid potential, in accordance with the varying intensity of a signal impulse to be detected, the blocking action may be manifested before the oscillations reach their maximum value, as determined by the constants of the tube, and that the maximum amplitude of the intermittent oscillations obtaining in the system is directly dependent upon the varying intensity of said signal impulse.

Detecting Small Electric Currents

No. 1,455,458: Patented May 15, 1923. Patentee: J. S. E. Townsend, Oxford, England.

The object of this invention is primarily to provide a simplified instrument whereby the wave length of electrical oscillations can be readily measured. The instrument may, however, be used merely



Means of measuring wave length by sight.

for detecting the presence of small oscillating currents.

It has been before proposed to employ an incandescent electric lamp bulb for detecting electric currents, but hitherto it has been possible to use such a detector only when the current is fairly large, that is, large enough to heat the filament from its normal condition to the temperature at which it becomes incandescent.

According to this invention I employ an evacuated bulb having its filament connected in series with a choke coil and a battery of sufficient strength to heat the filament to a temperature slightly above or below the point of incandescence, so that the lamp is in a sensitive condition to show visually any small change of temperature due to the passage through the filament of a small current, and I superimpose the current to be detected upon the current flowing from the battery through the filament, so that the addition of this small current to the normal current may cause a change in the condition of the filament, which change is easily distinguished by the eye. Such a detector is especially suitable for showing alternating currents or currents of high frequency, and may be used either to detect the currents or to indicate when they attain a maximum value.

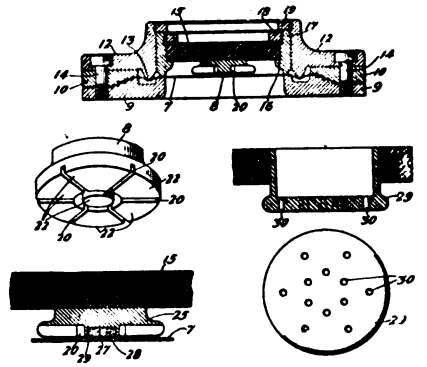
Acoustic Apparatus

No. 1,456,538: Patented May 29, 1923. Patentee: Irving B. Crandall, New York, N. Y.

THIS invention has reference to improvements in acoustic apparatus for the transmission, reproduction, recording, analyzing and measuring of sound waves. More particularly it relates to telephone transmitters, one of its objects being to produce a transmitter that gives practically a uniform transmission over a greater range.

It has been found that diaphragms such as are used in telephones, phonographs and other acoustic apparatus have a more or less marked natural period for one or more frequencies, and if acted upon by waves of these frequencies will respond more than for materially different periodicities. The natural frequency depends in general on the mass, and stiffness of the diaphragm, decreasing with increase in mass, but increasing with increase of stiffness.

In the usual telephone diaphragm the lowest natural frequency is in the neighborhood of 1,000 cycles per second, which is well within the range of those frequencies used in speech. Because of this natural periodicity and the resulting inequality in response to impulses of different frequencies a telephone diaphragm will distort speech



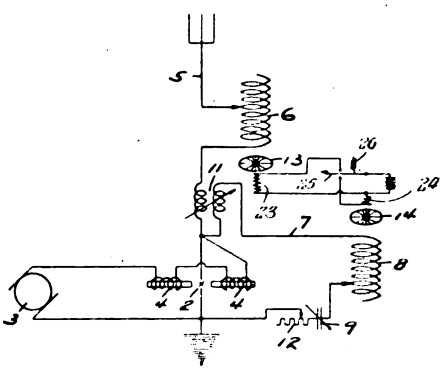
Improvement in diaphragm construction as applied to phones.

waves which are impressed on it when the resonance point of the diaphragm falls within that range which is of importance in speech. If, however, the elasticity or the stiffness of the transmitter is increased sufficiently this resonance point will be removed outside the speech range, and there will be a substantial equality of response to all impressed frequencies of the same intensity over a wide range of frequency. This maximum response at the resonance point could also be considerably decreased in value by increasing the damping factor of the vibrating system. The damping factor in general depends only upon the frictional forces and upon the inertia, being directly proportional to the frictional forces and inversely proportional to the inertia or mass of the moving system. Increasing the damping factor therefore gives a vibrating system a frequency characteristic of response more nearly of the ideal form.

Radio Telegraphy Signalling System

No. 1,454,629: Patented May 8, 1923. Patentee: H. F. Elliott, Palo Alto, Cal.

An object of this invention is to provide an efficient uniwave signalling sys-



Means of providing uniwave transmission.

tem for radio transmitting stations. The invention possesses other advantageous features.

Answers to Readers of Radio World

I have been told that by using one tube and a crystal detector in a reflex circuit that I can get louder signals and longer distance than by the use of the detector and one stage of audio-frequency. Is this so? Why?—Carl Kinesta, Maryville, Ky.

You can obtain louder signals and longer distance with a reflex such as you mention. The reason is that with a one tube reflex circuit you are getting one stage of radio frequency amplification, and one of audio-frequency amplification, in connection with your crystal detector. With the other circuit you would only be using the tube as an audio-frequency amplifier, and here you are gaining the use of an added stage of radio-frequency.

* * *

Is it possible to guarantee a circuit to receive foreign broadcasting stations? I have received a circular from a radio manufacturer that states that he will positively guarantee his set to receive English broadcasters anywhere in the United States on two tubes and an outside antenna. Is this possible? A Constant Reader.—Kansas City, Mo.

It is a pretty difficult thing to guarantee the receiving range of any set, as there are many conditions that have to be considered, and we have never heard of a set that is guaranteed to receive over such distances. You had better investigate it thoroughly before purchasing. The statement "anywhere in the United States" is quite a large order, and while receivers have been made that will get English broadcasters along the eastern and central parts of the United States, it is not probable that a two tube set is capable of such work.

* * *

Which is the more efficient form of radio-frequency amplification, tuned impedance coupled, transformer coupled, or resistance coupled?—A. G. Grant, 1673 Broadway, N.Y.

As far as efficiency is concerned, the tuned impedance coupled is the best. This is because of the fact that transformer coupled and resistance coupled are only capable of receiving on a very narrow band of wave length, and on all others it will receive with decreased efficiency. By using tuned coupling, you are enabled to control the wave length of your amplifiers and therefore get the best response from your tubes.

* * *

Kindly explain how I could repair my tube. I broke the tip off, and the vacuum was lost.—Ezekial Henderson, Camp Kumwatchee, Indiana. General Delivery.

It is impossible for any one to repair tubes unless they are equipped with apparatus necessary, such as mercury pumps, and a full line of glass blowing equipment, as well as a most complete knowledge of lamp-glass blowing. It takes more than a knowledge of how it should be done.

* * *

Will you kindly publish a diagram of the Flewelling Circuit? What plate voltage should be used in this circuit? Will it operate a loud speaker? What tube should I use in this circuit?—Joseph E. Healy, 114 Cypress Ave., Bronx, N. Y. Alfred Neff, 23 Chatham St., San Francisco, California.

The Flewelling circuit was published in Radio World for March 24. From 45 to 60 volts is correct for the plate voltage. It is doubtful if there will be enough volume to operate a loud speaker on one tube; however, with one stage of audio-frequency you will be able to operate one. Would suggest that you use one of the U. V. tubes as you are looking for volume. This circuit will operate on dry cell tubes but the volume will be greater when the larger plate surface tubes are used.

* * *

Is there any advantage in winding coils and tuners with Litz wire? Are there any books published which will show me the different forms of winding coils? Where can they be obtained? Is my enclosed description of Litz wire correct?—George Stepanek, 3328 Portland Ave., Minneapolis, Minn.

The advantage gained in the use of Litz wire in the winding of coils is the lowered resistance and greater inductance. We advise you to get the book titled "Ideas for the Radio Experimenter's Laboratory," by M. B. Sleeper. It can be obtained from the Columbia Print Co., 1493 Broadway, New York City. It gives several ideas for the winding of coils and inductances that are of value to the radio enthusiast.

* * *

Where can I obtain a sketch or blue print of a set using five tubes using two stages of radio-frequency, detector and two of audio-frequency amplification?—John Budge, 65 McGregor Ave., Toronto, Ont., Canada.

A suitable circuit for this purpose was published in Radio World for June 30, in the "Answers to Readers" department.

* * *

In Radio World for March 24, you published a photograph of B. R. Mayo. Where can I obtain his address?—Mrs. C. B. Holden, Midland Park, N. J.

The address of B. R. Mayo is 2761 Broadway, New York City.

* * *

On page 16 of Radio World for June 2, you published an article by W. S. Thompson, on a simple reflex set. Where can I secure a diagram of this set in "long hand," as I am not familiar with technical diagrams? Can the set mentioned be used with the U. V. 199 tubes? Can a variocoupler or variometer be used with this set?—Carl E. Morrison, 545 62nd St., Brooklyn, N. Y.

From your description we understand that you cannot translate a diagram. Suggest that you take the diagram in question to some friend that is familiar with such things and have him help you, as the description that you ask for would take up too much space to allow us to print it. The set can be used with these tubes. Yes, it is possible to use this set with a variocoupler by connecting the secondary of the coupler in place of the loop, and using an antenna and ground.

* * *

I constructed the single circuit regenerative receiver that was described in Radio World for April 24, by Arthur S. Gordon. I have checked this circuit very carefully, but cannot get anything out of it. What is my trouble?—Reinhold Dalhm, R. R. 2, Box 44, Hartford, Wis.

Your diagram is correct, and we suggest that you examine the grid leak and condenser and make sure that all your connections are good. Soldering them is best. If you have hooked the set up exactly as your diagram shows there is no reason for the circuit not operating, as it is absolutely correct. Make sure of your B battery, and see that your antenna is not grounded.

* * *

Will you please publish the circuit diagram that is used by Myrle Wood, in your Nite Owl Records of Radio World for June 2? Can honeycomb coils be used in this circuit for long waves?—R. Babylon, 3024 Fern St., New Orleans, La.

The circuit diagram as used by Myrle Wood was published in the issue you mention. You cannot use honeycomb coils in connection with this circuit. You can load it up by the use of the coils you mention; but the fact that it uses variometers will naturally limit the range of such practice.

* * *

Which is more efficient as to distance work, a three tube reflex or a single circuit receiver with two steps of amplification? Is the circuit used in the De Forest D7 a reflex circuit? Is regeneration necessary in order to receive telephone signals? Is a crystal set capable of regeneration?—William Morris, 345 West 54th St. New York City.

The more efficient of the two sets mentioned is the reflex if properly constructed and tuned. This is because of the fact that radio-frequency amplification is used, which allows amplification of the signals before rectification. With a single circuit set, with audio-frequency amplification, no signals can be amplified that are not heard in the detector alone. The De Forest D7 is a reflex circuit. Regeneration is not necessary in order to receive signals. A crystal set is not capable of regeneration.

* * *

Can I use the —— coupler in a reflex receiver, using a crystal detector? Where may blue prints of reflex sets, with panel layouts and all necessary data be furnished? —James R. Kaker, Str. "Malutoa," Sault Ste. Marie, Mich.

The coupler you mention can be used in connection with the reflex circuits. We do not handle blue prints of circuits. Apply to S. Newman & Co., 74 Dey Street, New York City.

* * *

Where can I obtain instructions as to the exact tuning in of long distance stations using the set described in Radio World for May 12, by C. H. Stoup?—J. H. Parkhurst, 221 S. Ashland Blvd., Chicago, Ill.

Information as to the exact tuning of any particular set is very difficult to give, as it is only by familiarity with your own set that you can learn how to tune any set, even a crystal set. In order to properly tune any set you must practice and get used to it.

* * *

Is there any practical method of eliminating static?—Joe Kavanaugh, 519 Grant Ave., Hoboken, N. J.

Static cannot be entirely eliminated, but it can be diminished by the use of a loop antenna. If an outside antenna is used no series condensers should be used in the antenna-ground circuit, and the use of a short, low antenna will help. See article on static by Kenneth Malcolm in Radio World, June 2.

* * *

Will you publish a diagram for two stages of radio-frequency detector and two stages of audio-frequency in a set? Will it enable me to receive from 200 to 600 meters? Will it work on a loop?—Walter Mack, 806 No. Windomere, Dallas, Texas.

A diagram such as you wish was published in Radio World for June 30 in answer to a question by A. Hallam. It will enable you to receive over the wave band you desire. It is possible to work the set on a loop.

Digitized by Google

What the Public Likes in Broadcasting Programs Partly Shown by Letters

AT the close of radio programs announcers invariably ask the audience to express its appreciation or criticism in writing. "We want to broadcast programs which you like, and unless you write we will not know what you enjoy," they say.

Dr. Burton, of the University of Michigan, in a baccalaureate sermon, said: "The first requisite of valuable public service is not the desire to find out what most of the people want, but the purpose to help people want what they ought to have."

The big question in the program director's mind is whether to give the public what it wants or learn what it should have and broadcast that, says a writer in the New York *Times*. A radio impresario entertains the largest audience of any showman, and he can lose his audience in a second. Few people walk out of a theatre, circus or concert if the program is not what they desire, but a slight turn of a radio dial and any member of the audience can free himself from the theatre of the air without disturbing the others. The station which radiates a program that the people "ought to have" is generally a victim of tuning out as the dials revolve to bring in some other station broadcasting what the listeners want.

Based on the quality and merits of music, opera and classical selections are what the music masters say the public "ought to have." Letters received at the radiophone studios show that great differences exist between that estimate and what the radio audience wants.

What does the public enjoy most? This question is answered in part by the letters. However, these represent but a small percentage of the audience. Comparatively few express their applause or criticism in writing.

Believing the Volstead Act to be something many people do not want, and others think the nation ought to have, the impresario of WEAF selected as part of an evening program a prohibition debate between prominent wet and dry leaders. Considerable interest was aroused, as indicated by telephone calls which overburdened the wires with questions from radio listeners. About 2,000 letters were received from the estimated thousands who tuned in on the debate.

To determine how many listened to the prohibition arguments and other features broadcast from the station a survey was conducted through the co-operation of sixty newspapers. The general plan was to obtain a fairly accurate figure relative to the number of receiving sets tapping the ether within a 100-mile radius of WEAF's aerial. The census showed about 13,600,000 persons living within that radius, and the results of the survey indicated about 600,000 receiving sets.

A study made by the Radio Corporation of America pointed to a division of the radio audience into two general classes—one which wants jazz and the other classical music. New stations are generally provided with two studios so that a classical concert and dance music can be broadcast simultaneously.

Telephone calls and letters addressed to the program directors indicate clearly that jazz bands are the favorite of youth. A symphony orchestra and opera bring correspondence expressing appreciation and is apparently the most pleasing form of musical entertainment to many of the older listeners. The trend seems to indicate that the radio audience is growing more critical in its tastes. It is admitted that light music is appreciated by many, but several program directors believe jazz is merely a diversion to be heard at intervals rather than regularly.

There is a great gap between the listener who wants dance music and the one who favors high-class selections. The middle group of listeners seldom take time to write to a radio station.

Large sales have been recorded in the radio business on advance notice that a prize fight would be sent into the air, blow for blow, direct from the ringside. Football games and the World's Series baseball contests stimulated the sale of radio instruments to a marked degree. A conquest for supremacy is a radio event which entertains the mass of those listening in. People the world over throughout history have found pleasure in conquest, so this favorite program of the radio theatre is little different from the programs in the coliseum of ancient Rome, the lists of England and the arenas of Spain.

Just before a contest is broadcast many people invest in a radio receiving set to hear the contest direct, first hand, the instant it happens, whether the result be a knockout, a touchdown or a home run. Music has its charms, but a fight for supremacy and championship fascinates and quickens the pulse even by radio.

During the last few months WEAF has broadcast a program at 11 a. m. daily. Many wondered if such broadcasting would be worth the time and expense because few persons would be listening at such an hour. Correspondence shows that the morning program entertains a new audience—women at home and people who work at night. Correspondence from women has more than doubled, and many of those who work at night write to tell how the 11 o'clock entertainment affords the only opportunity they have to tune in. It is estimated that about 7 per cent of the population of New York works at night, so the 11 o'clock audience is not a small gathering.

Musical comedy selections are popular, as they travel through the air especially to listeners in outlying districts. The effect of broadcasting one act of the musical comedy "Wildflower" through the microphone was called a revelation. For several weeks afterward every performance was sold out, and the largest advance sale ever reported for the Casino Theatre was recorded. Radio evidently gave sufficient suggestion of the quality of the performance to attract hundreds to the box office.

R3 Magnavox Radio The Reproducer Supreme

Make Your Receiving Set Complete

The efficiency of the Magnavox Reproducer is due to its principle of construction.

Only the Magnavox (electro-dynamic) reproducer can re-create broadcasted programs according to their original *pitch, quality* and *volume.*

Without Magnavox equipment, no Radio receiving set is complete.

Magnavox R3 Reproducer and 2 stage Power Amplifier . . . $90.00

R2 Magnavox Reproducer with 18-inch curvex horn: the utmost in amplifying power; requires only .6 of an ampere for the field $60.00

R3 Magnavox Reproducer with 14-inch curvex horn: ideal for homes, offices, etc. . . . $35.00

Model C Magnavox Power Amplifier insures getting the largest possible power input for your Magnavox Reproducer.

AC-2-C, 2-stage, $55.00
AC-3-C, 3-stage, $75.00

Magnavox Radio products can be had of good dealers everywhere. Write for copy of our new booklet.

Crosley Holds Jobbers' Convention

THE Crosley Manufacturing Company held a jobbers' convention at its home offices in Cincinnati, Ohio, on July 10 and 11. There were present representatives of the largest jobbing houses of the country to inspect the Crosley company radio plant, wood-working shop, printing office and broadcasting station, WLW. Numerous valuable suggestions for the marketing of radio products were advanced during the sessions of the meeting, most of them in correction of past mistakes in the industry as a whole.

De Forest Elects New Officers

AT a recent meeting of the board of directors of the De Forest Telephone & Telegraph Company, Jersey City, N. J., the following officers were elected: E. H. Jewett, president; Chas. Gilbert, vice-president and treasurer; and R. M. Keator, secretary.

$1,000,000,000 Gain in 1923 Crop Value Considered Big Thing for Radio

Radio manufacturers, distributors and dealers should go right out for the farmer trade.

A government forecast shows that the crop value in this country for 1923 will show a gain, at the present market prices, of $1,000,000,000 (one billion dollars) over the crop value of 1922.

The farmers are going to have money.

They can afford to buy radio sets.

Sell 'em!

Dr. Gildersleeve's Set Goes to the Veterans—Six Tubes Needed

FOLLOWING the suggestion of RADIO WORLD, made in last week's issue, Dr. Donald M. Gildersleeve, 169 Prospect Park West, Brooklyn, N. Y., generously has donated a six-tube receiving set to the Veterans' Mountain Camp, Big Tupper Lake, N. Y. The set goes forward this week to the officials in charge of the camp.

The set is a Rico JM-6 and is complete with the exception of the necessary six tubes. Now, will one or more readers of RADIO WORLD come forward with the tubes? Their prompt generosity will complete Dr. Gildersleeve's fine gift. De Forest, Radiotron, or Cunningham tubes may be used.

Gentlemen, the veterans can't listen in without tubes for their new set!

That Stencil List of Radio Manufacturers and Dealers

A trade reader of the Merchandising Department of RADIO WORLD has asked for information as to the number of names of radio manufacturers, jobbers and dealers obtainable from concerns having stenciled lists. Inquiry has been made of one of the most important list dealers in this country, and we are informed that a corrected, up-to-date and authoritative list of the names wanted would show the following figures:

Radio manufacturers	1,826
Radio jobbers	1,758
Strictly radio retailers	3,867
	7,451

And that seems to be the answer.

Western Electric Does Big Business

FIGURES of the Western Electric Company show that its billed goods were valued at $114,890,000 in the first half of 1923, an increase of $15,237,000, compared with the same period last year. Orders booked in the first half of this year approximated $142,805,000, which is $57,363,000 more than last year.

Orders Show Big Increase

THE Westinghouse Electric and Manufacturing Company reports new orders valued at $47,500,000 in the second quarter of 1923, against $32,119,000 in the same period last year.

New Radio and Electric Firms

Electrial Thermal Machinery Co., manufacturing apparatus for electrical heat treatment of metals and alloys, $1,000,000; Edwin S. Pickett, Jos. E. Perry, New Haven, Conn.; Daniel J. Keefe, West Haven, Conn. (Corporation Service Co.)

Volton Battery Co., New York City, has increased its capital stock from $5,000 to $20,000.

The Improved Electric Products Co., Cleveland, Ohio; capital, $10,000; manufacture and deal in electrical devices; incorporators, H. D. Weinstein, Wayne C. Black, M. Becker, G. H. Brunswick and W. G. O'Haren.

McPhilpin Radio Electric Corporation, Brooklyn, N. Y., has increased its capital stock from $20,000 to $30,000.

Barclay Electric Co., New York City, has increased its capital stock from $20,000 to $25,000.

Brackman Electric Co., Rochester, N. Y., $50,000; A. L. and C. Brackman, R. J. Jauss. (Attorney, W. V. Armstrong, Rochester.)

Harlem Radio, New York City, $5,000; H. C. Bernheim, M. Lovett. (Attorney, M. L. Gilman, 27 Cedar Street.)

Mu-tron Radio Corp., install radios, $250,000; George A. Blackford, Wheeling, W. Va.; A. Tegarden, Martin's Ferry, Ohio; T. M. Darrah, Wheeling, W. Va. (Attorney, Horace G. Eastburn, Wilmington, Del.)

Status of American Telephone & Telegraph Co.

THE American Telephone and Telegraph Company, parent company of the "Bell System," had net working capital of $113,214,961, according to its balance sheet as of March 31 last, current assets standing at $138,334,102 and current liabilities at $25,119,141. On December 31, 1922, net working capital amounted to $99,695,528. Its report to the Interstate Commerce Commission shows net operating income of $13,427,554 for the first five months of the current year against $11,228,459 in the corresponding period of 1922. Operating income for May was $2,643,284 against $2,437,947. Net earnings of seventy telephone companies for the four months ended April 30 last totaled $48,225,509, an increase of $7,736,354 over the first four months of 1922. Operating revenue was $210,723,542, an increase of $22,041,534.

Daily Newspapers Publishing Radio News and Programs

AS a part of its service to readers RADIO WORLD publishes herewith the names of daily newspapers which carry radio programs and radio news. Wherever possible the name of the radio editor of the paper is given. Additions to the list will be published as received.

The Lawrence Daily Eagle (morning), The Evening Tribune, Lawrence, Mass. Howard G. Lewis, radio editor, care The Eagle. Both publish daily radio programs and a radio column.

Daily Evening Item, Lynn, Mass. Clayton L. Carpenter, radio editor. Prints daily radio program.

The Evening Sentinel, Ansonia, Conn. Prints daily radio programs of nearby stations.

The New Haven Register, New Haven, Conn. Publishes same radio programs as The New York Tribune. H. I. Jenks, radio editor.

Worcester Evening Post, Worcester, Mass. Publishes daily radio programs from stations broadcasting in New England, North and Middle Atlantic States. Address communications to Radio Editor.

The Standard, New Bedford, Mass. Evening and Sunday. Carries daily radio programs and a full page of radio news on Sunday. Lester I. Jenkins, radio editor.

The New Bedford Times, New Bedford, Mass. Evening and Sunday. Daily radio programs. Full page of radio news on Sunday. Leonard Finnell, radio editor.

Boston American, Boston, Mass. Publishes daily nearly complete programs of six or seven stations and a schedule of evening and night broadcasting hours of 30 to 40 other stations.

Des Moines Sunday Register, Des Moines, Iowa. Publishes a summary of leading station programs for the ensuing week. James D. Le Cron, radio director.

Pine Bluff Commercial, Pine Bluff, Arkansas. Evening. Radio column discontinued during summer. Probably resume daily programs and radio news about October 1. James E. Miles, Jr., radio editor.

The Springfield Republican, Springfield, Mass. Daily, Sunday, weekly. Publishes radio programs daily and Sunday. Arthur F. Hardwick, radio editor.

The Hartford Courant, Hartford, Conn. Conducts regular radio departments. Publishes daily detailed programs of prominent broadcasters. Also operates its own broadcasting station, WDAK, and presents a weekly program every Saturday night. John R. Donahue, radio editor.

(To be continued)

In the Market for Many Items

EDITOR, RADIO WORLD: We are just building our models and patterns of radio apparatus, and we need much material, but have difficulty in finding the right parties who manufacture and sell same at lowest prices. To house our apparatus we want manufactured for us "wood fibre cabinets" of similar materials to that in fibre water buckets, and finished in ebony, walnut, etc., at a low price to cut out high priced cabinets. We also need wood rotors, rotor axles or shafts, cardboard and fibre tubes, aerial wire, magnet wire, insulated lead in and ground wire, insulators, binding posts, dials, contact point, switches, switch stops, crystal detectors, headphones, washers, nuts, machine screws, brass rods, round and square, condensers, transformers, tubes, etc., etc.. We must buy them as low as possible to reduce the present high prices on radio apparatus and will sell direct to users only.

Yours truly,
ADAM SCHICK.

Vinland, Kansas.

Radio Certainly Boosted These Songs and Music

EDITOR, RADIO WORLD: In regard to Broadcaster-Music Publisher fight I can truthfully say if it were not for the broadcaster I would not have heard and bought every new song or musical piece that I have at present. I have bought as high as seven pieces per week and also the same with records.

Every opera that was broadcast by WJZ when the station was in Newark was attended by at least three of my family or friends who had listened with me.

Yours very truly,
R. W. FINTER, SR.

126 Wainwright St., Newark, N. J.

Radio Parts Wanted by This Buyer

EDITOR, RADIO WORLD: I will purchase about $1,500 stock of standard radio parts before September 1 and would like to get in touch with manufacturers making good quality items, including fixed and variable condensers, vario-couplers, variometers, H. C. coils, storage and dry batteries, cabinets, etc. I will be located at San Antonio, Texas, and would appreciate your service.

Very truly,
GEO. L. EDWARDS.

Gibson, Mo.

Robin Radio Shop Opens New Quarters

AFTER a successful year at Craig Street and Centre Avenue, Pittsburgh, the Robin Radio Shop has been obliged to move to larger quarters at 3602 Fifth Avenue, Pittsburgh.

Right Side of Store More Valuable

IF your store has only one entrance the right side is the more valuable, says Harry Botsford in Electrical Merchandising. He continues:

An electrical merchandise dealer in Harrisburg, Pennsylvania, brought the matter to my attention. I consider him as one of the very best retailers I have ever known.

"The right hand side of my store is easily worth four times the other side," he told me a month ago. "This is a fact and not a mere theory. I've been in business for over ten years and I'm considered a fair business man, yet several months ago I discovered that something has been happening in this store every day, and I have never noticed it. And what I discovered has a direct bearing on sales, too!

"As you know, I am strong for service to customers. Originally, I had one telephone pay-station in the rear of the store. I managed to convince the telephone company it would be good business to install two telephones there. Each telephone was placed on a small table, fitted with a chair, at opposite sides of the store. Each was equally convenient and there was no reason in the world why one should be used more than the other. Yet at the end of the first month, the telephone on the right had taken in just four times the number of nickels the other had. I gave the matter scant consideration. The next month the same thing happened. That gave me the theory on which I subsequently worked.

"I decided on several experiments to prove whether or not people naturally had a habit of turning to the right when they enter a store. I had had for two weeks a very good-looking display of hair-driers and curling-irons in my front-center showcase. The sales on these items were very low for that period—only three had been sold, to be exact. I moved the display over to the right hand side of the store. The very first day it was there we sold more than we had sold before in two weeks.

"That almost convinced me; but I made other experiments. A display of electric flashlights and renewal batteries which had been selling very well on the right side of the store were moved to an equally well-lighted showcase on the left side of the store, and the sales dropped just an even 95 per cent. I have tried plan after plan of shifting and the net of my results is that I sell about four times the goods on the right as I do on the left."

Radio Trade Notes

The plant of the Virginia Radio Corporation at Charlottesville, Va., recently was damaged by a $10,000 fire. The loss was fully covered by insurance.

* * *

Ashton Bremner, 1 Margaret St., Oxford Circus, London, W. E., England, is open to represent American firms interested in the British market.

* * *

Rocky Mountain Radio Corporation, 1512 Broadway, Denver, Colo., is in the market for cheap crystal detectors, knocked down.

* * *

Arthur Unger, formerly assistant manager of the Permanent Radio Fair, New York City, has become a radio manufacturers' representative, with offices at 30 East 23d Street, New York City.

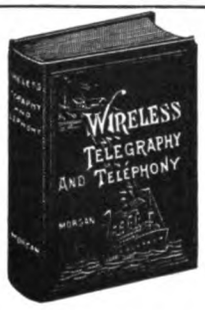
Radio Books for Your Vacation

Telling How to Operate a Radio Set—How to Build a Set—Principles of Vacuum Tubes and Other Radio Problems



Wireless Telegraphy and Telephony Simply Explained

By ALFRED P. MORGAN

One of the most complete and comprehensive treatises on the subject ever published. A study of its pages will enable one to master all the details of the wireless transmission of messages. The author explains in simple language the theory and practice of wireless telegraphy and telephony. 154 pages, 156 engravings.....PRICE $1.50

The A B C of Vacuum Tubes Used in Radio Reception

By E. H. LEWIS

Assoc. I. R. E., and Radio Instructor

Written particularly for the person who "knows nothing about radio," but who would like to gain an understanding of the elementary principles of operation of vacuum tubes and various circuits in which they are used for the reception of radio-telegraph signals and radio-telephone music and speech. Illustrated.....PRICE $1.00

Experimental Wireless Stations

By P. E. EDELMAN

Tells how to make apparatus to not only hear all telephoned and telegraphed radio messages, but also how to make simple equipment that works for transmission over reasonable long distances. Then there is a host of new information included. The first and only book to give you all the recent important radio improvements, some of which have never before been published. 392 pages, 167 illustrations....PRICE $3.00

IMPORTANT NOTICE

While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

New Type Radio Control for Airplanes

A NEW type of automatically directed airplane performed marvellously before Marshal Petain and other high army officers at the Villa Coublay aerodrome near Paris recently, according to a press dispatch.

The control device consists of a roll of perforated paper as that of a player-piano roll. The movement is directed by wireless from the ground. As the roll moves it sets in action mechanical arms and legs which direct the plane, control the motor and release bombs.

The new craft marks great progress over other automatically controlled aircraft because there is less electrical apparatus on the airplane.

Oakland Broadcasters Increase in Number

THE Oakland *Tribune* in California is planning to increase the power of its broadcasting station, and hopes by October to be in a position to apply for a Class B license. At present KLX is operating as a Class C station on 360 meters with a power of 250 watts. New apparatus for a 500-watt set has been ordered from the Western Electric Company, and, with a 300-foot antenna, a far wider broadcasting range is planned this fall.

There are seven broadcasters in Oakland and its vicinity, two B stations and four A stations being in San Francisco, across the bay. The new General Electric station

THE BOY MECHANIC

700 THINGS FOR BOYS TO DO

480 Pages—700 Articles
800 Illustrations — Cloth

Price $2.00 Prepaid

The Ideal Book for the Wide-Awake Boy

All the things described in this volume have actually been built or experimented with by boys. The ideas contained in "The Boy Mechanic" would more than keep a boy occupied until he grows up and also be an incentive to original thinking and achievement.

The Most Interesting Boys' Book

Unlike so many other books of a somewhat similar nature, it is not confined to only one or a few subjects, but describes 700 different things boys can make and do in the fields of mechanics, electricity, sports, arts and crafts work, magic, etc.

An unusually generous book; size 7 by 10 in. and 1½ in. thick; printed from large, clear type on high grade book paper and durably bound in cloth. Attractive four-color cover design.

Wholesome, Practical, Instructive

Besides telling how to make scores of things useful about the house, full and complete directions are given for constructing hundreds of things which appeal to the heart of every boy.

Many hours of enjoyment are in store for the boy who becomes possessor of this book.

Radio Locates Line Trouble

WHEN the two St. Croix transmission lines of the Northern States Power Company tripped out at 1:55 P. M. on January 30, both telephone lines to St. Croix were put out of commission, according to the Electrical World. F. J. Gerlich, superintendent of the service department, lost no time in getting to the radio set, and upon tuning in immediately heard the wireless operator at St. Croix calling Minneapolis. By means of radio-telephone communication the trouble on the transmission lines was quickly cleared up, and both lines were back in service by 2:05 P. M. (within ten minutes). Wire telephone communication was not re-established until half an hour later.

FIL-KO-STAT

FOR REAL FILAMENT CONTROL

Trailing Fake Battery Sellers

WITH purpose to curb and, if required, to aid in the prosecution of deceptive advertising in the storage battery field, the national vigilance committee of the Associated Advertising Clubs of the World and its affiliated better-business bureaus and commissions have launched a campaign against unscrupulous manufacturers and dealers. The vigilance committee contends that some service stations known and advertised as the authorized representatives of well-known manufacturers are prone to trade upon the established good name of reputable concerns through the substitution of foreign or inferior parts in the reconstruction of batteries.

Summer Schedule of WIP

GIMBEL BROTHERS, Philadelphia, who operate Station WIP, inform RADIO WORLD that they will not broadcast any program on Saturdays or Sundays during July and August. The regular seven-day-a-week schedule will be resumed on September 1.

"B" BATTERIES

Government Wants Radio Engineers

THE United States Civil Service Commission announces the following open competitive examinations: Radio Engineer, $4,000 to $5,000 a year; Associate Radio Engineer, $3,000 to $4,000 a year; Assistant Radio Engineer, $2,000 to $3,000 a year.

Applications will be rated as received until October 30. The examinations are to fill vacancies in the positions named, or in positions requiring similar qualifications. in the federal classified service throughout the United States.

The duties are to conduct or superintend the development, design, construction, installation, standardization, and the writing of specifications for practical and special apparatus and methods of radio communication, such apparatus to include sets for land use for more or less permanent stations, also for portable land stations, and for airplane and ship sets, and similar lines.

Competitors will not be required to report for examination at any place, but will be rated on the following subjects: Education and preliminary experience, 30%; special experience and fitness, 40%; publications, reports, or thesis, to be filed with application, 30%.

Full information and application blanks may be obtained from the United States Civil Service Commission, Washington, D. C., or the Secretary of the Board of U. S. Civil Service Examiners at the post office or custom house in any city.

Forthcoming Features of Program at WGY

THE Georgia Minstrel Boys, one of the most popular of recent attractions at WGY, the Schenectady broadcasting station of the General Electric Company, will give another program July 27. Within twenty-four hours of their last program 1,400 letters were received by the station.

Monday evening, July 23, Edna Schuyler, pianist; Mrs. Fred Harris, contralto, and Rosina Holmes, reader, will appear. The program on Tuesday night will be presented by the Gibson Mandolin Club, Joseph Carroll, tenor; Edith MacCulley Corlette, reader, and Ethel Mincoff, pianist. The mandolin club will play the type of selections that sound good on the water—the kind you like to hear as you drift along in a canoe.

"The Royal Mounted," a four-act play by DeMille, will be presented Thursday night, July 26, by the WGY Student Players, assisted by three members of the WGY Players.

A classical program is scheduled for the late or 10.30 p. m. program Friday. The artists will be Raymond Sachse, piano; Lloyd Beebe, cornetist; Raymond Stine, reader, and Leo Kliwen, violin.

Sunday, July 22, the morning service of the First Reformed Church of Schenectady will be broadcast, and in the evening a studio religious service will be broadcast, with a sermon by the Rev. Robert W. Anthony.

Coming Events

AMERICAN RADIO EXPOSITION, Grand Central Palace, New York City, October 6 to 13, 1923. J. C. Johnson, general manager.

ANNUAL HOME AND CITY BEAUTIFUL EXPOSITION, featuring radio exhibits, Atlantic City, N. J., June 16 to September 8, 1923.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEER, Pacific Coast convention, Del Monte, Cal., Oct. 2-5. F. L. Hutchinson, 33 West 39th St., New York.

WYG Gets 65,000 Letters from Fans

SINCE the inauguration of broadcasting by WGY, sixteen months ago, the General Electric Company has received 65,000 letters from listeners scattered over the United States and from points as widely apart as Hilo, Hawaii, and London, England; Vancouver, Canada, and Valparaiso, Chile.

Some of these letters are typewritten and from the offices of business and professional men and some are penciled on scraps of paper from woodsmen and from forest rangers. All the letters acknowledge appreciation of the broadcasting service the General Electric Company is giving and, by the very fact that they are written, prove that the writer feels that the company addressed has a heart, is interested in the letters and receives them sympathetically and appreciatively.

Until WGY began broadcasting, the mail of the General Electric Company was made up of the usual type of business and technical letters. Broadcasting began a veritable flood of warm, personal missives in many of which intimate facts relating to the family were unbosomed. The listener feels that the voice coming out of the air is that of a friend. It enters his home and provides pleasure and entertainment for all the members of the family circle and in acknowledging appreciation the writer addresses the station as a friend.

An elderly woman wrote WGY in part as follows:

"Accept my thanks for the two sermons yesterday. I am a poor, hopeless invalid and they were most comforting. I shall be waiting for the coming Sabbath for you have brought something into my life I had never expected to enjoy again."

Another, also an invalid, wrote: "I have been an invalid for over twelve years, confined to my wheelchair or couch nearly all that time and it is indeed a great privilege to hear the dear old hymns which I love so well and the word of God so faithfully proclaimed. It helps me forget my suffering for I am a great sufferer. * * * It is little I can do to help carry the burdens of the world but at least I can keep sweet and WGY helps me do it."

A mother told how each of her children enjoy the WGY concerts, even an eighteen months' old infant, she said, was comforted when the phones were placed over its head. A blind girl related how she had grown melancholy and depressed and then radio came along and she now has a daily joy to anticipate.

WGY requested letters from listeners when the station was started because those in charge of the technical operation wanted to know the quality of the transmission and the range of the station. When these facts became known the announcers continued to ask for letters because these letters constitute the only applause which the radio performer gets, and a large number of complimentary letters is an inspiration. So far as the performer in the radio station is concerned he has only the word of the engineers that his solo is being radiated many miles. When the letters come he knows that the words sung in the radio station in the presence of only his accompanist and an announcer, have taken flight over many states and brought pleasure to countless homes.

These letters are also useful to the program manager for from them he learns what type of program appeals to the majority of listeners and the letters strongly influence his decisions in building up future programs.

After a recent minstrel show broadcast by WGY 1,400 letters were received by

Construction of New Type Transatlantic Receiving Sets

By M. B. SLEEPER

Fully Illustrated. Price 75 Cents

IN addition to the listening to ships and broadcasting stations on short wave lengths there is a peculiar fascination about listening to the high-power telegraph stations of England, France, Germany, Russia and Italy as well as those located in the Pacific Ocean and the Oriental Countries. It is much easier to do this than most people imagine. The sending is very slow, a feature of assistance to the beginner in telegraphy. Several types of receiving sets for this task are described. Detectors, amplifiers, oscillators, etc., for long distance reception are also described. Suggestions for the operation of relays by the signals and the reproduction of them on a phonograph are given. In addition there is some valuable data on home made wavemeters for testing and experimenting.

Sent P. P., prepaid, on receipt of price, by

RADIO BROADCASTING MAP

FOR the benefit of those interested in Radio and those who are becoming interested, Rand McNally & Company have prepared a publication containing a wealth of information of greatest value. It shows, in the most comprehensive way, the location of the broadcasting stations, gives their classification, the call letters, wave lengths, ownership, etc., of each.

The Rand McNally Radio Map of United States is 28x30 inches in size. The locations of broadcasting stations are shown by distinctive symbols. The call letters of each station are given, also the wave lengths of each. The Radio Districts with numbers are shown in red and the Radio Relay Divisions are in blue. Time zones are included. Alphabetical lists of stations and alphabetical lists of call letters are in the margins. Convenient pocket form with cover.

Local Commercial Radio Service in Denmark

RADIOTELEPHONE connection between Copenhagen and the island of Bornholm in the Baltic Sea, heretofore poorly equipped with means of communication, is now an accomplished fact, Trade Commissioner Sorensen reports. Radiotelephony between the two points is now open to the public. The radio circuit, which consists of the four stations of Amager, Lyngby, Hammeren and Ronne Radio, is based on the Poulsen arc system, manufactured by the German firm of Lorenz. The installation permits of communications in either direction simultaneously. The radio is connected with the ordinary Copenhagen telephone system, so that any subscriber may ask for a number on Bornholm Island and get connection. The cost for a call is 3.50 crowns for a three-minute period.

One of the Types You Meet

HE comes down to the office looking as though he had walked all night with his darling child. He is continually reading radio magazines, he talks radio, he eats radio, he sleeps radio and he works radio.

When you go out to lunch with him he always takes the lunchroom next to a radio store, bolts his sandwiches and coffee, and then stands outside of the store and looks longingly at some particular piece of apparatus. Then suddenly he gets an inspiration, goes in and buys some funny looking thing, comes out with a broad smile and hustles through his afternoon's work so as to be home early.

Next morning he comes in looking seedier than ever. When you ask him what is the matter, he spouts a bunch of station calls all over his vest and looks like a miner that has just picked up a ten pound nugget and hasn't a relative in the world. THAT'S HIM—THE RADIO BUG!

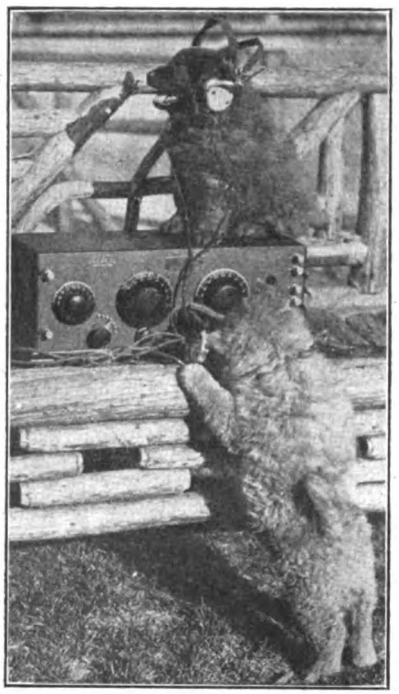
Chows Listen In For Prices of Chow



(C. Underwood and Underwood)

No brethren, this does not signify that radio is going to the dogs, but it does show that even Chinese Chows (aristocrats of dogdom) appreciate something out of the ordinary in a good concert. The announcer at the time this was snapped was giving the price of prime knuckle bones and Chinky, sitting up atop the set, is having a hearty laugh at the fact that they dropped three cents per pound. Blinky, down below, is hard of hearing in the right ear, so he takes the initiative of listening with his left ear in between both phones so that he won't miss a single price.

Suggestion to Song Writers

WE have had songs about Dear Old Dad, and Dad's Wife, and Sweetie songs, and Dearie songs, and Banana songs, and Mamma songs, but what a reader wants to know is who is going to write that popular piece (it's bound to be popular, and think of the millions that it will hit) "My Ma's Got the Radio Bug Now," or "Pa, Turn the Juice Off, Soup Is On the Table."

Comparisons Are Odious!

MARY: "Huh, smarty! My father is a bootlegger."

Alice: "As though that was anything—my daddy owns a radio shop."

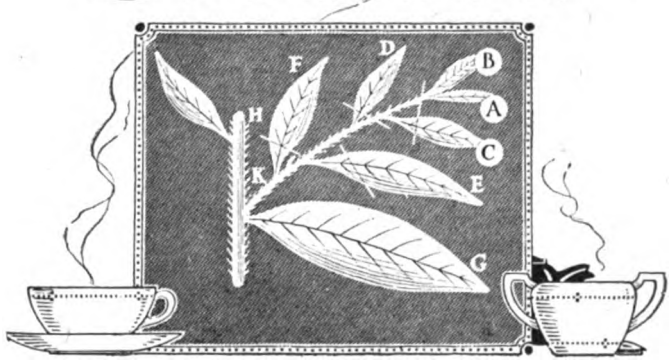
The A.B.C. of Good Tea



THIS diagram shows clearly one reason for the superior flavor, strength and aroma of RIDGWAYS TEA.

The plucking season commences in the early Spring and continues right into the Autumn. At the commencement of the season, the plant sends forth its first tiny shoots. In order to get the very choicest pickings, only those leaves marked "A," "B" and "C" are gathered for Ridgways. These tender, young tip-leaves give to Ridgways Tea that rare quality of flavor which distinguishes the famous Ridgway blends. The leaves marked "D," "E," "F" and "G" are coarser and less flavory and therefore *are never used by Ridgways.*

This carefully guarded Ridgway quality also assures more cups to the pound. When you buy Ridgways Tea you not only get the best tea, but actually more of it than is possible from inferior tea. As an example of rare good tea we suggest that you order Ridgways (GOLD LABEL), the *Genuine* Orange Pekoe.

Be Sure to Insist Upon

Ridgways Genuine Orange Pekoe Tea

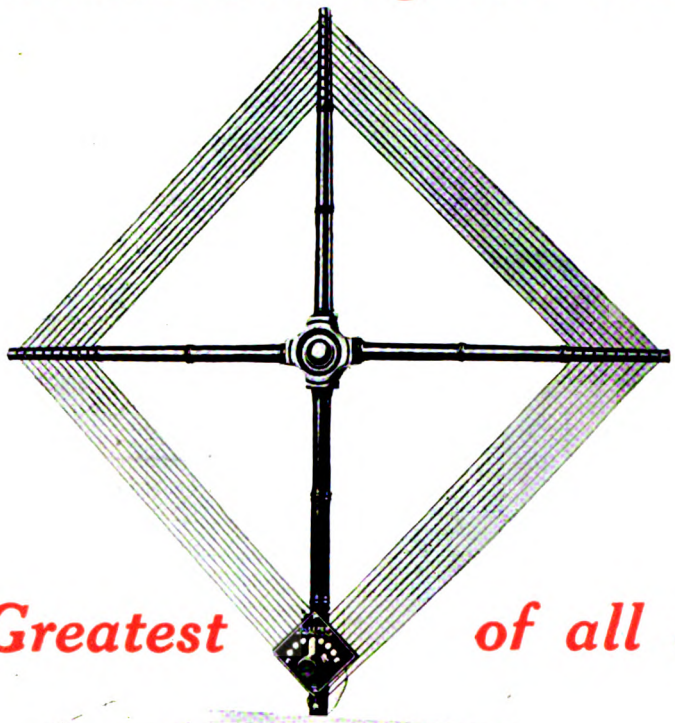
It was well worth waiting for the Monotrol

The most perfect reception you have ever heard



From the most beautiful set you have ever seen

Latest and Greatest of all 3-Tube Sets

The New Grimes Inverse Duplex Circuit

3 Tubes do the work of 5 with no outside wires

SLEEPER MONOTROL

Trade Mark Registered

WITH exclusive rights to the famous Grimes Inverse Duplex Circuit we were bound to build the most perfect Radio Set in America.

This patented circuit is the **only** system which can use the **same** tubes in inverse direction for both radio and audio frequency amplification. Distortion is impossible. The tones are absolutely **pure.**

The twirl of a single dial—the "Monotrol"—tunes in or out all stations. You will always pick up the same station at exactly the same number on this dial and selectivity is so great that you can tune through powerful local stations and catch distant stations without the slightest interference.

The volume also is so great that, with three tubes only, it is equivalent to any five-tube set and permits the use of a loud speaker **without power amplifiers** for all middle range stations.

No outside wires or ground connections are used.

The beautiful Windsor period loop gives you a full range, reduces static practically to zero and with its patented Sleeper loop taps, provides perfect control of volume intensity without affecting tuning.

There are many other distinctive features which you will note with pleasure and surprise when you hear this remarkable set. Any Sleeper dealer will demonstrate these features to you. In the meanwhile, write for our descriptive booklet. Make certain that the latest and greatest of 3-tube receivers is the set you have been waiting for.

Col. Green's Loud Speaker Causes Protest

STATION WMAF, owned and operated by Col. E. H. R. Green at his summer home at South Dartmouth, Mass., which was illustrated and described in last week's RADIO WORLD, is the subject of a protest from the residents of Nonquit, Mass., six miles away. The battery of loud speakers mounted on top of a water tank is causing the objection.

With a desire to let his neighbors share the programs from prominent broadcasting stations, Col. Green not only installed the loud speakers, but allowed free entree to his estate and even provided automobile parking space. Hundreds came nightly. Scores of automobiles lined the road and parked in the meadows.

Colonel Green and his guests enjoyed the experiment, but the Summer colony at Nonquit, six miles away, did not. First came a faint stir of protest and then a roar. Colonel Green was surprised by the protests, so he has announced that the concerts will be discontinued until horns and mechanism can be so arranged that the sound will not carry to Nonquit.

Bishop Bars Amplifier from Altar

BISHOP WILLIAM T. MANNING has ordered removed from the high altar of the Cathedral of St. John the Divine, in New York City, a receiver for a system of amplifiers.

"Nothing of a worldly nature should be in this sacred place," he is quoted as saying. "Besides, communicants should know their service by heart, and it should not be necessary for them to hear the words of the celebrant."

The altar receiver was a part of a system recently installed at a cost of $9,000. There are nine amplifiers throughout the cathedral, and now even the choir and clergy can hear every word of the sermon. The bishop himself, seated on his throne, can "listen in."

No objection to the amplifier system as a whole was made by the bishop. He merely held that the placing of a receiver on the altar was carrying "modernism" a little too far.

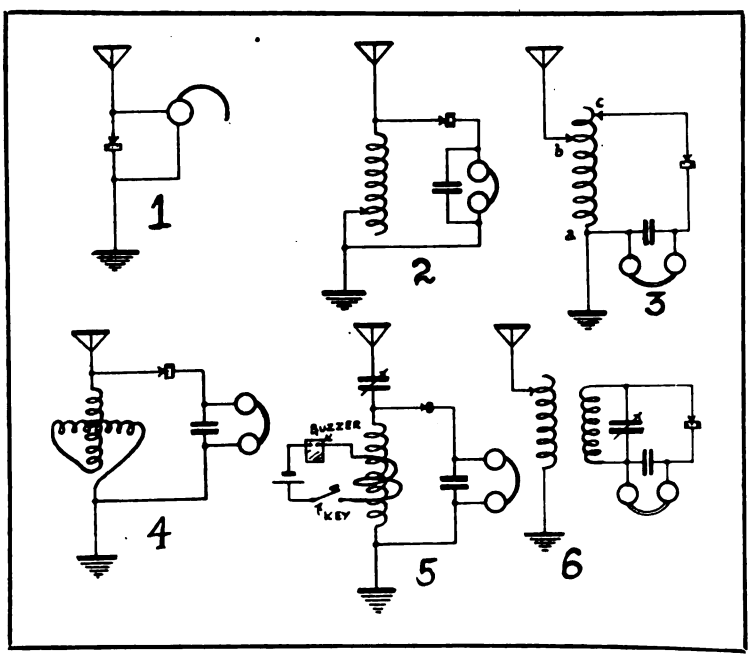
Single Crystal Sets for Broadcast Listeners

By Kenneth M. Swezey

MANY aspirant broadcast fans become discouraged when their glances at every turn collide with a complicated diagram or a high price. In its year or so of existence, the army of listeners has advanced to such a degree that the radio shops and the magazines have to keep going at a good pace to satisfy its demand. The result is that the beginner with the very modest pocketbook is often forgotten. Not so very long ago the question when fan met fan was this: "What kind of a crystal are you using now?" Today the question would be more likely, "What kind of a tube do you recommend for the sixth amplifier stage?" Yes, times have changed; but crystal sets are as good now as ever they were, and, within their limitations, will give very satisfactory service.

In the first place, crystals are very efficient as radio detectors; even much more so than the vacuum tube. Although sometimes they are rather difficult to adjust and to keep in adjustment, they do not distort the incoming waves. The chief thing to recommend them to the beginner, however, is the simplicity of the crystal set and the comparative inexpensiveness. The disadvantages might include the lack of stability and sensitivity as compared with the vacuum tube. Located within 25 miles of a good broadcasting station, and used with ear-phones, a crystal outfit ought to give very satisfactory results.

The simplest form of a crystal set that is workable consists of a detector, a receiver, and the usual aerial and ground connections. This circuit, shown in Fig. 1, is the type generally used in "tie-pin," "nut-shell," and other very tiny sets. The disadvantage is that such a set cannot be tuned, but must respond to waves whose lengths approximate that of the natural wave length of the aerial and ground system.



Figs. 1 to 6. Simple circuits suitable for broadcast listeners.

In Fig. 2 we have the simplest crystal circuit that is really practical. In addition to the crystal and phones, it has a small fixed condenser and a single slide or tapped tuning coil. The condenser is not used for tuning at all, but merely affords a by-pass for the radio-frequency waves around the high resistance phones, and also stores the audio-frequency rectified waves and discharges them at the proper time through the receivers. The tuning coil generally consists of a number of turns of insulated wire wound around an insulating cylinder, or tube, and having a slider that can be adjusted so as to make contact with any desired turn. For broadcast reception, with a 100-foot aerial, the coil could very well have about 80 turns on a three- or four-inch tube. The tuning is accomplished simply by moving the slider back and forth, cutting turns in or out as desired.

By adding another slider we have the more selective set, shown in Fig. 3. Here we really have a two-circuit receiver, with what is known as *conductive* coupling. The turns of the coil that are included between a and b might be considered as the aerial circuit, or primary, and the turns between a and c, the closed circuit, or secondary. This is quite a good circuit, is fairly selective, and is widely used by beginners. In many cases rotary switches and taps are used in place of the sliders, thus allowing better mechanical construction and mounting on a panel.

For short waves, the variometer lends itself very well as a tuning device, in the manner shown in Fig. 4. With one of average design, a range of wave length

(*Concluded on next page*)

Digitized by Google

Single Crystal Sets for Broadcast Listeners

(*Concluded from preceding page*)

between 300 and 500 meters ought to be secured without difficulty. Such a set would have but one control to manipulate, besides the detector adjustment. For longer wave lengths a loading coil could be connected in series.

Fig. 5 shows a crystal circuit that is quite good for short wave work. Here the tuning is accomplished by means of a variable condenser of about .0005 to .001 mfd. capacity in series with a fixed coil. The fixed coil, in this case, is not a useless piece of loading, but is included to sharpen the tuning qualities of the circuit. A long aerial wire has good absorptive qualities, but it does not allow of the sharp tuning that could be obtained by the addition of a concentrated inductance in the form of a coil.

This diagram also includes a buzzer test outfit, which device allows the adjustment of the detector at moments when there are no stations coming in. It consists of simply an ordinary buzzer, or one of the high frequency type that are made especially for the purpose; a dry cell; a key, switch, or push button; and a small coil of a few turns of wire which is placed near, or in inductive relation to, the fixed tuning coil. When

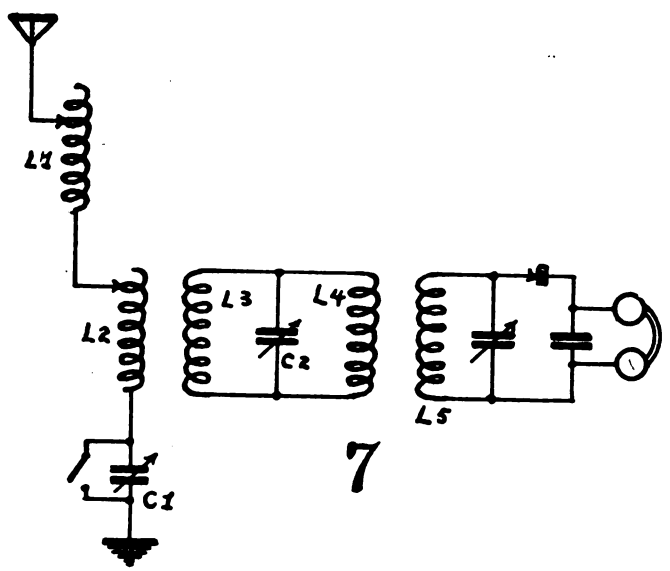


Fig. 7. Crystal set circuit which is quite selective.

the buzzer is in operation, the detector can be adjusted to its most sensitive point without the aid of incoming signals. This test outfit can be used with any of the sets described.

The crystal receiving set that has two distinct circuits is slightly more complicated than those just mentioned, but in a number of ways it is more satisfactory; the most important is that it is more selective. Sets having loose couplers or variocouplers are of this type. The coil that is in the aerial circuit is called the *primary* and the one in the detector circuit, the *secondary*. If the secondary has a fixed value, a variable condenser is usually connected across it to vary the wave length. For broadcast reception, the primary should have about 80 turns, and the secondary—if it has a variable condenser across it—should have about 40 turns. To get such a set into operation the detector must first be adjusted, if you have a buzzer test, and the secondary condenser set at some arbitrary point. Use very close coupling between the two coils. Now move the primary slider, or adjust the primary switch, until a station becomes audible. Next adjust the secondary condenser for maximum response. A change in the coupling might now make the signals louder, or reduce the interference from another station that is not desired. Loose coupling will tend to reduce static disturbances, as static is less capable of jumping between coils that are inductively coupled than are radio oscillations.

An arrangement that is still more selective is shown in Fig. 7. Here we have an intermediate circuit consisting of fixed inductance coils L3 and L4, tuned by the variable condenser C2. The aerial coupling coil L2, and the detector circuit coil L5 are not in inductive relation to each other, but are connected solely through the intermediate circuit. In practice, two variocouplers would do very well for the four coils mentioned. The primary of one as L2, the primary of the other as L5; and one secondary as L3 and the other as L4. The two couplers should be separated at least six inches. C2 is an ordinary .0005 mfd. variable condenser. If waves beyond the normal range are desired, the loading coil L1 may be included in the circuit. For shorter waves put in the series condenser C1. For some of the lower wave lengths it may be necessary to have a fewer number of turns on L3 and L4, than that of secondary of the average coupler.

Crystal detectors are voltage actuated devices, and therefore it is desirable to have a preponderance of inductance, rather than capacity. That means that wherever possible, coils should be used in preference to condensers. This, however, does not apply to the phone condenser. This last named condenser should, for usual practice, have a fixed value somewhere between .001 and .005 mfd.

The crystals that are used most at the present time for detectors are galena, silicon, and a few synthetic crystals that go under different trade names. Of natural crystals, galena is the most sensitive, with silicon as a fairly close second. However, a great deal depends upon the individual crystal. Some of a particular kind are extremely sensitive, while others are just the opposite.

There is a mistaken impression that crystals must be changed every few weeks or months. This is unnecessary. The author has a good piece of galena which he has used in a detector over a period of eight years, without even having a cleaning, and without any appreciable signs of deterioration.

Exposure to the air causes a thin film of oxide to accumulate, which might render the crystal less sensitive. Handling with the fingers renders a crystal insensitive, by depositing on it a coating of oil or grease. If oxidized, a new surface may be prepared by scraping with a knife; or better still, by splitting off a thin layer, along the line of cleavage, which is most likely parallel with the present surface. An oil film may be removed with alcohol or ether.

The knack of finding the sensitive spot comes with experience. The crystals above mentioned require a very light contact for maximum sensitivity. A long straight or coiled, catwhisker or phosphor bronze, with a rather sharp point, does fine. Scrape the point occasionally to remove any accumulation of grease and dust. Mounting the detector on a rubber or felt base will tend to prevent the adjustment from jarring out.

Except in rare instances, a crystal set cannot be used with a loud speaker. And except when very close to a broadcasting station, it cannot be used with a loop aerial. There are no crystal regenerative sets, but crystal detectors are used to good advantage, in connection with vacuum tubes, in some of the new reflex circuits. Vacuum tube amplification may be added, if so desired.

Army Center Handles 322 Messages Daily

By Carl H. Butman

WASHINGTON, D. C.—All War Department telegrams, cablegrams and radio messages are handled directly through the Army Message Center located in the Munitions Building, and under the direction of Maj. General Geo. O. Squier, Chief Signal Officer of the Army. An average of 322 messages a day is now handled, the bulk of the dispatches being sent and received by radio.

As a financial saving to the government, the Message Center is a unique factor. Through the operation of its radio it has reduced the telegraph tolls from $5,500 in July, 1922, to $1,650 in March, 1923. It is a "paper" saving, based upon commercial rates. The peak of traffic was valued at $6,599 on May 1, but in July the estimated value of the total traffic at commercial rates will be about $9,000.

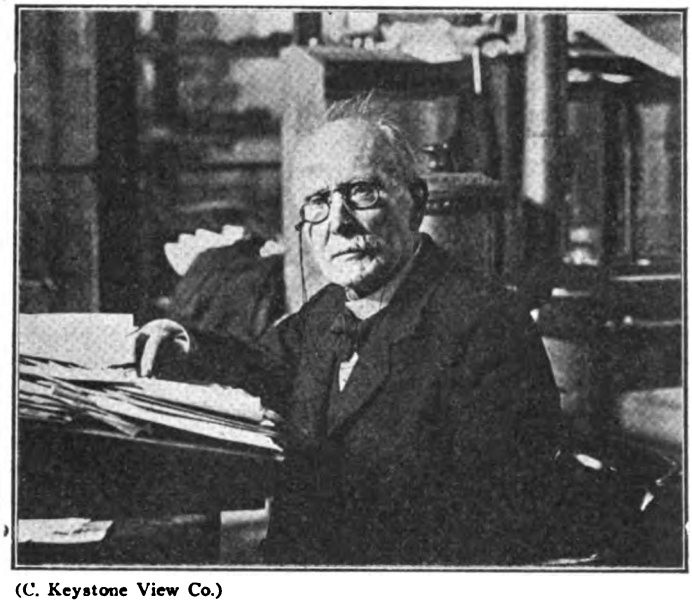
Through the use of its radio net, now including 112 stations in every corner of the country, the Message Center handled 62,222 official radiograms, totaling 2,235,417 words during the last calendar year. If this traffic had been handled over commercial telegraph lines, the cost to the Government would have been $38,202, but the Army cost was only $18,039, exclusive of enlisted operating personnel. The saving to the country amounted to $20,163.

The Message Center presents a busy scene at any hour of the full twenty-four during which it is operating. The central office where Capt. R. B. Wolverton presides, handles all messages from the many bureaus of the War Department in Washington. Both in and out messages are cleared through his office. Near at hand is the telegraph room, moved three months ago from the War Department, where all Army telegrams are sent and received. In another room are four loop radio receiving sets of the latest Signal Corps design. Reception of the many outlying radio stations is handled by four rotable loops on the roof of the building. The loops are revolved to the proper angle for receiving a station by long brass rods subtending to the radio room below. Two operators are on watch constantly, but by means of schedules traffic is handled at specific hours.

Arlington is the sending station for all outgoing government radiograms, the Army sharing the station with the Naval Communication Service. Three sets at Arlington are controlled directly by land line during certain periods of each day by the operators at the Army Message Center. Special lines for signalling the Arlington electricians parallel the remote control lines. One set is used primarily for communication to Air Service flying fields on 1,500 meters. Another set operating on 1,900 meters is used for sending dispatches to Fort Hayes in Ohio, and Fort Bragg, N. C. The third is a tube set transmissing on 2,650 meters, used for communicating with Fort Benjamin Harrison, Ind., and eventually Fort Leavenworth, Kan., and Fort Douglass, Utah, when the new 10 KW tube sets there are completed. Fort Leavenworth is expected to be ready for operation by August 1st.

High speed transmission and reception has been tried out with good results. With the Kleinschmidt automatic apparatus which sends from a perforated tape and receives by recording in Morse dashes and and dots on a tape, a speed of at least 100 words per minute is planned between Fort Benjamin Harrison, Ind., and Washington. The type of high speed apparatus is capable of 150 words per minute, and it is

Transmits Light by Radio



(C. Keystone View Co.)

This is the "Father of Wireless in France," Edouard Branly, of Paris. He is sometimes known as the Grand Old Man of Wireless owing to his early invention of the coherer. He now claims to have succeeded in transmitting by wireless a luminous point and a circle of light, thus opening up the possibilities of vision by wireless. M. Branly is 77 years old, an eminent scientist, and was elected to the French Academy of Sciences in 1911.

South Dakota College Man Saves Ship by Radio

YANKTON, S. D.—Stranded for eight days on an island in the Mediterranean, after an accident in which two sailors were killed, the S.S. "Manhattan Island" was rescued by destroyers through a distress message sent out by the radio operator, Homer Fitch, formerly a boy amateur of this place and member of the American Radio Relay League.

A report of the accident and the part played by Fitch was received here from Constantinople to which port the "Manhattan Island," a government Shipping Board vessel, proceeded after having been dredged out of the sand by vessels coming to the rescue.

The vessel was on its way to Constantinople from Palermo, Sicily, when it ran aground. Fitch, who is only 19 years old, was the only operator aboard and it was his skill at the key, gained while an operator at the Yankton College radio station 9YAK, that brought the desired aid to the ship stranded on the island shore.

At one time a student at the college, Fitch will exchange his officer's uniform for a football suit next fall. He made his letter for the last two years as guard and center. He obtained his first position as radio operator through friends in Texas whom he knew only through communicating with them by radio. expected that it will prove efficient in handling traffic during peak loads.

Radio and the S. S. "Leviathan's" Trial Trip

By Pierre Boucheron

ONCE a telegraph operator, always an operator. Whatever effect the dots and dashes may have on the psychology of a person who becomes a master of that staccato language the facts remain that the clicks of the sounder or the buzzes of the radio have a fascination that never dies.

And the latest proof of this simple philosophy is to be found in what transpired aboard the great ship "Leviathan" during her recent trial trip from her berth in Boston harbor to the warm waters of the southern Atlantic and back again to New York City. While press accounts have been replete with details of the huge liner's notable passenger list on that occasion, of her gigantic dimensions and her splendid appointments, of her reconditioning from a troop transport of the stirring days of war to our mightiest merchant ship, and of the startling records made during the trial run, little has been said or written regarding the radio equipment of the "Leviathan."

Yet when the huge liner set out on her trial trip under the critical gaze of the American public the time had come for the acid test of the super-radio plant installed on the new "Leviathan." Soon messages began to pour into the radio quarters aboard from men of every calling, for her list of guests was a representative cross-section of American business and public life. Soon there was a large volume of radio traffic from passengers aboard to relatives and friends and business associates ashore.

So far so good. But shortly after, when the chief radio officer, E. N. Pickerill, called the radio coastal stations and announced to America at large that the flagship of our merchant marine was under way, these stations flashed back the significant information that they had batches of urgent messages for the "Leviathan," all ready to be transmitted.

Pickerill, old-time operator that he is, with a wealth of experience and a skill that is second to none, was in a quandary. The notable passengers aboard were besieging Pickerill to dispatch their radiograms post-haste, with ever-increasing volume of dispatches; while the coastal stations were pressing him to take their radiograms without delay. Never before had such a problem presented itself to a ship radio operator.

It was at this point in radio affairs that David Sarnoff, vice-president and general manager of the Radio Corporation of America, and a guest on the "Leviathan," happened into the radio cabin to look things over. Mr. Sarnoff was in a sports suit and smoked a large cigar, obviously set for a few moments of leisure snatched out of a tireless business activity. "How is traffic?" he inquired of Pickerill. And the latter, surrounded by a rising tide of radiograms, hastily explained the extraordinary situation to the executive.

Now Sarnoff is a man of action. He knew that something had to be done, for the radio equipment of the "Leviathan" was just as much under the scrutiny of the American public as the turbines or the crew or the guests of that ship. The traffic had to be handled without loss of time no matter how voluminous it might be. So Sarnoff repaired to Mr. Lasker's stateroom, where he discussed the situation with the head of the U. S. Shipping Board. "I believe," concluded Sarnoff, "that the American public is entitled to know as quickly as possible, through the medium of the newspapers, of the progress of the finest liner under the American flag. For that reason I believe we should temporarily withhold transmission from the shore stations in favor of the 'Leviathan's' transmission." Mr. Lasker agreed. So did the men of affairs aboard the great ship. Soon Sarnoff was instructing all shore stations to receive press traffic from the "Leviathan" first, and when all the radiograms had been dispatched from the ship they could, in turn, transmit their accumulated messages.

With the plan of action settled it was quite another matter to reduce the pile of radiograms that had collected in the radio cabin. Sarnoff required no consultation with any one in solving this problem, for he is the man who, ten years back, while stationed in New York, received the dispatch from the steamship "Olympic," 1,400 miles out at sea, giving the first confirmation of the sinking of the "Titanic" after a crash with an iceberg. He is also the man who, seven years ago, when radio telegraphy alone was considered an accomplished fact, presented a detailed plan to his superiors, which conceived a simple radio telephone "music box" for every home boasting of a talking machine. This plan is today in actual use in the form of radio telephone broadcasting.

Little wonder, then, that Sarnoff, the man who has been through every stage of the radio business, from messenger boy to radio operator, and then to inspector, engineer, commercial manager and traffic manager, and then, still higher, to vice-president and general manager of a great radio corporation, felt the irresistible urge once more to handle the traffic of America's pride of the seas. In a moment he was a changed man. All his executive problems—if he had them on his mind during what had started out to be a restful trip—were temporarily put aside, and Sarnoff set himself for the task of clearing the accumulating radio traffic, giving Pickerill a much-needed reinforcement.

With his coat thrown off and sleeves rolled up Sarnoff took his place at the key, while Pickerill relayed the message blanks for G. Harold Porter, general marine superintendent of the Radio Corporation, and also trial trip guest, who took the bundle of messages presented by newspaper men and others at the doorway of the radio cabin. News soon passed around that Sarnoff had assumed the role of chief communication officer, and in a short while radiograms aggregating 15,000 words or more were placed before the telegraph operator, who at one time was the fastest in the service.

The limit of physical capacity for transmitting radiograms was soon reached. It was at this time that Pickerill, sizing up the situation, hit upon the idea of starting up another transmitting set for the purpose of handling part of the ship's traffic on another wave length, it being at the same time that Sarnoff was steadily unloading the radiograms that lay before him, thus relieving the pressure brought to bear by an all-but-overwhelming traffic. The generators were started, and shortly the second transmitter got into action on another aerial provided for emergency use. A hurried call to the nearest coastal station was answered by "Get you fine. Shoot your messages."

So two separate radio transmitters worked away on board the "Leviathan," with Sarnoff at one key and Pickerill at the other—two star operators intent on their work. The two transmitters sent and received at the same time without mutual interference, each communicating with

(*Concluded on next page*)

Digitized by Google

(*Concluded from preceding page*)

its own shore station. The rate of dispatching the radio traffic was, of course, doubled. The pile of radiograms soon melted away under this relentless onslaught of skilled operators as they were placed in the hands of the shore operators. The "Leviathan" was all the while linked on the one hand with a station at Boston, and on the other with the station at Chatham, Mass.

Sarnoff from that point on took his trick with the operators—namely, John R. Irvin, Anthony Tamburinio and R. J. Green—in four-hour shifts. Rarely have radio operators sat at their keys ticking away constantly for four-hour shifts. Aside from taxing their ability they became fatigued from their tedious job, but nevertheless one operator was always on hand to do a few minutes' relief work while the man on duty rested his arm, which was suffering from muscular strain. Two days after leaving Boston one of the operators became exhausted, and one of the relief men was snatching a few hours of well-earned sleep. Again Sarnoff answered the call. Attired in a tuxedo and after a hurried meal he arrived in the radio cabin, removed his coat and went to work again, pounding the key for two hours at a stretch, while Porter arranged for filing the dispatches.

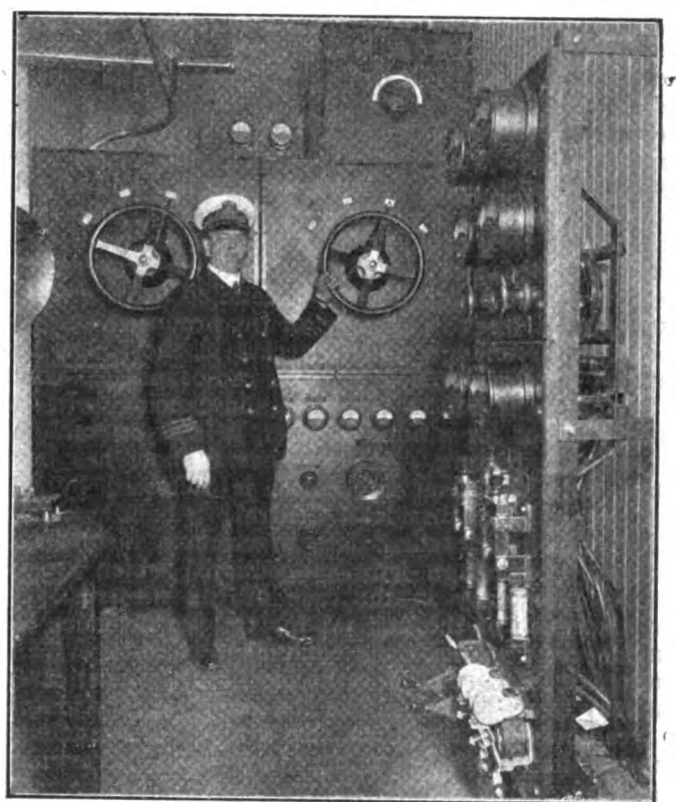
During the brief lull in the radio business Pickerill was reminded of the fact that he had promised to call his wife, living in Brooklyn, N. Y., via the radio telephone equipment—the only one, by the way, of its kind installed on a merchant ship. This feat was accomplished by calling the Bush Terminal radio station, which normally handles radio telegraph traffic from and to ships at sea. After testing out the set Pickerill's voice went on the air. "Hello, Bush Terminal! Please call Mrs. Pickerill on the telephone when you get a chance and tell her everything is going fine," was the telephonic message of the chief operator.

Being the wife of a radio man Mrs. Pickerill has a radio set in her home, which she uses for receiving radio broadcast concerts. It so happened that Mrs. Pickerill was listening in when her husband's voice was sent from the "Leviathan," and she heard it perfectly. Upon receiving the voice message Mrs. Pickerill called Bush Terminal radio station by telephone, saying: "You need not bother with the message from Mr. Pickerill. I have received it at home."

Thus it will be seen that the radio telephone messages were readily heard by the very persons for whom they were intended. Indeed, the usual radio telephone is by its very nature an excellent means of broadcasting or disseminating information. In marked contrast the radio telegraph as employed in trans-oceanic work and for ship-to-shore communication assures a maximum degree of secrecy and privacy since the radiograms are in code and can only be deciphered by a skilled operator. For extreme secrecy the messages may be coded into cipher.

And so the "Leviathan's" radio equipment received its acid test, and was not found wanting in any particular. The main transmitter performed flawlessly, "pumping" from 30 to 40 amperes into the antenna. The auxiliary continuous wave transmitter of two-kilowatt capacity served to handle the overflow of traffic, as already mentioned. The radio telephone, of the duplex type, permitting two-way conversation, also did good work when called upon. The "Leviathan" even boasts two life-boats which are provided with radio equipment. These have not been, and, it is hoped, never will be, tried under actual conditions of service.

After the voyage was completed Mr. Sarnoff remarked that, due to the position of the "Leviathan" in tropical waters and the heat wave along the coast, static was abnormal. In fact, during all his experience as an operator prior to becoming an executive in the company, he had never listened to static of such great intensity and persistency. As a consequence, for the first time in the history of marine radio, it was necessary to use the Cape Cod high-power station and divert it from European communication to the "Leviathan's" business. The power and wave length of reception was then increased from four kilowatts and



(C. Radio Corporation of America)

High power tube transmitter on the S. S. "Leviathan." The picture shows the chief radio officer, E. N. Pickerill, changing wave length.

1,600 meters to 200 kilowatts and 16,000 meters. In diverting the high-power station at Cape Cod from European to ship communication the Radio Corporation of America in this instance placed at the disposal of the "Leviathan" radio facilities on shore costing about $2,000,000. Something like 40,000 words of press, private and official communications were exchanged between the giant ship and the American shore stations during the famous trial trip.

WRC, Washington, D. C., the Latest Broadcaster

WRC, the call to be assigned to the Washington Radio Corporation station this week, will identify that new station excellently, when it gets on the air. Officials of the corporation are planning to open the station on August 1, with due ceremonies and an excellent program, details of which are being arranged by the program manager Ralph Edmunds, formerly identified with several opera companies and moving picture interests. His active contacts with musicians and actors, it is believed, will serve Mr. Edmunds excellently in preparing and executing exceptional broadcast programs. WRC is a duplicate of the 2 K. W. New York station WJY and Z on Aeolian Hall, but at the outset, only about ½ KW of power will be used. All parts of the transmitter are in duplicate, so that in the event of a breakdown an immediate switch to the other circuit can be made to cover the emergency.

How Broadcast Central Transmits from Theatres and Hotels in New York

By J. L. Bernard

FEW people who read the radio programs have a clear conception of what is meant by the phrase "this concert will be broadcast by Station WJZ by direct wire from the ——— Theatre" or wherever the event is held. The layman's imagination does not seem to favor the idea of using wires in connection with radio broadcasting.

The heart of the "direct wire" system used by Broadcast Central is composed of three main arteries. In addition to these three arteries there are nine additional permanent wires, from which lines are run underground to Aeolian Hall Building, thence to the control room of the station. Various other net works of wires are tapped off, and which lead to the station from the main circuits. This artery system enables Broadcast Central to reach many points in Manhattan, and affords the radio audience a multitude of concerts, talks, and plays which they could otherwise never receive.

When a Broadway production is to be broadcast, a member of the program staff is detailed to review the play about a week in advance of the proposed date—if the play has enough of its success in the songs and lines, it is considered a suitable radio subject, while if its success is due to costumes and dancing, with no entertainment for a blind listener, it is of no value as a broadcast feature. Assume that a show has been found suitable—what procedure is followed by the "outside crew" of Broadcast Central? About two days before the broadcasting date a wireman installs the necessary backstage wire connections, which are of course, temporary in the case of the theatres. On the afternoon of the day set for the performance the outside crew set up their equipment backstage. The microphone is concealed in the footlights in most cases, but may be suspended above the stage. Everything is in readiness by the time the first of the audience straggle in, and the announcer, arrives in full evening regalia to introduce the theatre audience to the radio audience. The announcer generally has a microphone just back of the scenes, so as to be in close touch with all that goes on, but occasionally is given a small dressing room, with interphone communication with the stage. As soon as the performance is over the microphones are removed.

In the case of the Goldman Band Concerts on the Mall, which are being sent out from Broadcast Central, the wire is run through the trees in the Park, well out of reach of passers-by, to the main circuit, thence to the station by way of a lead-off. The wire is tied high up on one of the posts of the band stand, a table is requisitioned, and the microphone stands in full view of the leader. The announcer uses a separate microphone, and stands as near the leader as possible so that one may time his actions to fit in with the leader.

In St. Thomas' Church the installation is permanent, the microphone being properly located to effect perfect transmission from all parts of the service. There is a permanent installation in the Mark Strand Theatre and the music which is broadcast from this theatre every week has become one of the most popular of radio concerts. Everything is run according to schedule time, with no allowance for hitches or mishaps—not one has ever occurred. The theatre management has fitted up the screen room as a miniature broadcasting studio, and after the artists have completed their turns on the stage they may broadcast a purely radio program.

Visitors at the Waldorf-Astoria, the Plaza, the Commodore, and the Astor Hotels this past season have known the purpose of the little black disc suspended in the midst of the tea-room orchestra—but the uninitiated have wondered a bit. The little black disc is the microphone, the only part of the transmitting apparatus visible to the public. Hidden in the near background there are always two operators and an announcer. Because they always keep in the background very few of the diners and dancers at the various hotel roofs have realized that the music to which they danced was being sent out to all parts of the country—there is so little ostentation about it that it seems uncanny.

RADIO PRIMER

ANTENNA ERECTION: With the exception of sets employing loops in connection with radio-frequency, outdoor antennae have been the only method that the average amateur and fan have of receiving signals. Many erect an antenna without any thought as to the importance of various details that enter into its construction.

In order to be most efficient, the outdoor antenna should be clear of all objects such as iron structural work, tall trees and towers. To work properly, it does not have to be extremely high but should be high enough to clear all surrounding objects of this sort.

The insulation of the antenna is equally important. There is no sense of erecting an antenna if it is not well insulated, because poor insulation will only cause leakage of the minute currents with corresponding weakness in the received signals. The best insulators are those made of moulded composition with steel eyes in the ends. They are also the strongest and can be relied upon to stand up under any strain without rupture. If it is not possible to obtain these, the common porcelain cleat can be used. Two of these should be placed together for strength, and two sets of these at each end will give sufficient insulation, where a receiving set is concerned. The only bad point about the use of the cleats is the fact that they are very liable to become soot covered, and leak, but if they are cleaned every six months or so, they will stand up fairly well.

Another point that is generally neglected when an antenna is erected is the soldering of the lead-in wire to the antenna proper. If the wire is just wrapped around the antenna wire, the copper wire will corrode in time, and a poor connection will be the result. The lead-in wire should be soldered and taped and no trouble will be experienced from this end.

The bringing in of the lead-in wire is also another point that should not be neglected. A porcelain tube, or regulation lead-in insulator, should be used. In most cases the wire is just run through the open top of the window.

A Circuit to Play Around With

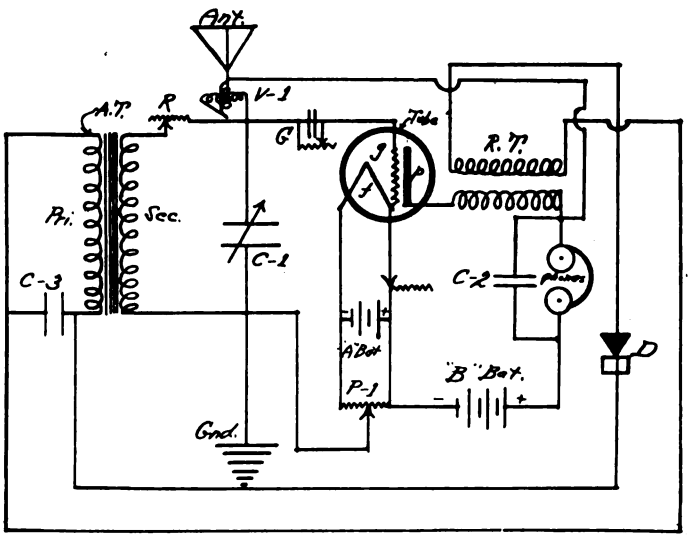
By C. White, Consulting Engineer

IF you are at present resting at ease and looking for something to play with I heartily advise you to fool around with the peculiar reflex circuit outlined in this brief article. But, before I start, I do not want anyone who has never built a radio set to decide to make this circuit his favorite receiver, because he will no doubt experience quite a little bit of trouble in making it work and the only man who can really make it function is the radio fan who has solved or assembled many radio circuits before and whose experience will be a guide to the correct results. Reflex circuits are always peculiar things to work because the constants for such circuits must be exact. In the particular circuit outlined I could get fair results with one audio transformer, no results at all with another, and still excellent results from a third. This in no wise reflects upon the quality of the various transformers, but it only goes to show that the constants of transformers greatly vary and you will always find that a certain one will fit a given reflex circuit better than any other for this reason alone. If you do decide to experiment with this circuit purchase a good reliable fixed crystal because an ordinary crystal will cause you much worry to get the right adjustment and keep the adjustment while you are changing things around in the circuit. At first you will discover that the action of the circuit is regenerative; that is, the crystal detector will make absolutely no difference at all in the circuit.

The schematic diagram gives the idea of the general assembly of the circuit. The variometer V-1 is no more than an ordinary variometer, and, the condenser C-1 is an 11 plate variable condenser. The resistance R should have a range of 1,000 to 100,000 ohms resistance. It is nothing more than a grid leak type of resistance. A grid leak resistance for the tube should also be variable, having such limits as advisable to employ with the type of tube used; that is, if a UV201A be used a leak varying from 2 to 5 megohms approximately should be secured. The grid leak condenser should be a fixed condenser having a capacity of .00025 mfd. The fixed condensers C-2 and C-3 should have a capacity of .002 mfd. apiece. The potentiometer P-1 must have about 300 or 400 ohms resistance, the latter value being more preferable. The audio-frequency transformer A.T. will play a large part in the correct performance of the circuit but it is almost next to impossible to specify any particular ratio because the right one will largely depend upon many constants of the other apparatus and wiring of the receiver. The radio-frequency transformer R.T. also plays a most essential part in the circuit and often by changing this around or trying another make you will discover very surprising changes in results.

After you have assembled the receiver keeping the grid leads as short as possible and you are all ready and set to listen in, most likely the first thing you will hear is a very strong alternating current hum. This immediately indicates one of two things, either you have made a mistake in the wiring and have an open circuit somewhere, or, the grid leaks R and G are not adjusted to the correct values. The latter is most likely to be the trouble and after playing around with these controls you will soon be able to alter the prevailing condition and eliminate the hum. After the hum is out of the way you will find that there are two ways to tune in a signal, either with the condenser C-1 or the variometer V-1, or maybe by varying both together. But, there is only one ideal condition and that is when the variometer is placed in a certain position and the final tuning is accomplished with the condenser. The wiring of the receiver permits it to be used as a regenerative circuit or a reflex circuit. You can readily ascertain which method you are using in the circuit by removing the fixed crystal detector D. If the signal completely falls out you know that the crystal was working, and if the crystal makes no difference in the volume then you know that the tube was acting as a detector. When the crystal functions you will note that the signal is much clearer than when the tube works alone, and the volume will be slightly greater. In reality there is a little combination of the two actions generally.

Although there is nothing wonderful or remarkable about this circuit, it does form a good circuit to experiment with if you have the necessary apparatus available. You will soon discover that there are many changes you can make and still have a good set or get clear reception. For instance, you can try removing



Schematic diagram of a reflex circuit that will surprise and delight the average fan who likes to have a little latitude in the construction of a set. It is important that a good ground connection be used with this set, because of the fact that a single circuit tuner system is used.

the grid leak and grid leak condenser G from the circuit and note the effect. Then try removing or varying R and note the changes. Change the size of the fixed condensers C-2 and C-3, change the types of radio and audio-transformers. Try out the various types of fixed crystals and discover which one gives the best rectification. I repeat that I do not recommend this circuit for the novice, that is, the radio fan who has never built or assembled a receiver. He is most likely to be puzzled at the various troubles that he will meet, but, the old radio fan will know from experience what to do. There are no parts in this receiver that are not standard and cannot be used in other circuits if you wish to do so later on, and therefore you will waste no money if you go to the expense to purchase a part or so to experiment with in this circuit. One of the greatest pleasures of radio I think is fussing around with new circuits, and it is very easy to do this experimental work if you live near one or more large broadcasting stations where you can experiment and test out your changes readily and without delay.

Naval Airship Will Carry Radio to Pole

By Carl H. Butman

WASHINGTON, D. C.—When the great Naval Airship ZR-1 goes to the North Pole, she will carry radio to the top of the world, whether it is late this summer or next spring. If she reaches that northern pinnacle, and experts insist there is no reason to doubt her ability, the Naval airship will be able to prove the fact by virtue of her bearing from northern radio stations. In these days of scientific achievement proof is required, and in the event an arctic explorer gets to the pole with a radio compass or a transmitting set, there can be no doubt of his exact position.

Together with a complete radio receiving and transmitting set, the ZR-1 is equipped with the latest type of radio compass, which at the pole would show radio stations picked up as bearing directly south, while at all radio stations within communication distance, her position would be due north.

By the time the aerial explorers are ready to start their northern flight, toward the end of August, MacMillan's radio experiments from the "Bowdoin" will have proven whether radio will carry through the aurora, a point on which there seems to be some doubt. MacMillan, however, will not be able to take his set very near the pole, but will be forced to abandon it and the "Bowdoin" at the edge of the ice, leaving it to the Navy to carry radio to the pole itself. Weather Bureau officials report that messages from Amundsen's "Maude" have been received by relay, and that a daily message on meteorological conditions is received regularly during the winter months from Spitzbergen located at latitude 78 north. If it is possible to put radio messages through from the far north, the world will hear of the ZR-1's progress and her arrival over the northernmost point on earth.

While Rear Admiral Moffett, Chief of the Naval Bureau of Aeronautics, and the crew of the ZR-1 believe the trip is feasible and are literally "rarin' to go," the date of departure depends upon her flight trials scheduled in August. Since the trip would only require a few days it is possible that it can be made before the long winter of the north sets in with its low visibility and extreme cold, but if tests and flights are delayed until September the exploration cruise may have to be postponed until next spring. No details as to route have been mapped out. Two courses are being considered, however, one directly north from Lakehurst, N. J., her home station, and the other northwesterly to Alaska, using Nome as an advance base. From Nome the course due north would be 1,766 statute miles, a little over a good day's run. The British R-34 crossed the Atlantic and returned to England in 1919, traversing a distance of over 7,000 miles in a week's time, and in 1917 a German Zeppelin made a cruise of 5,500 miles in four days. The cruising radius of the Naval craft is between four and five thousand miles, so the distance of the polar trip is not considered extreme for this 680-foot craft.

Meteorologists and Captain Evelyn B. Baldwin, an Arctic explorer, point out that while surface winds from the far north blow in a southwesterly direction, at higher levels the warmer currents bear toward the north and would aid a polar flight. Captain Baldwin, who suggested an aerial polar flight years ago, recently talked to the ZR-1 crew on polar exploration, answering innumerable questions. Among other things, he explained the advantages of a summer flight, as against one undertaken in darkness and cold. A winter trip, however, radio experts point out would aid radio transmission materially. But with her radio operating from a 300 foot antenna at a great height, it is felt that the aerial cruiser would be able to send satisfactorily in the Arctic day as well as in the night. According to Ralph Upson's report to the General Electric Company, in using radio from his balloon at an altitude of over 3,000 ft., he encountered no static whatever during the recent balloon race.

Radio stations in the north are fairly numerous, and it is believed that the ZR-1, once on her trip could keep in communication with several to check her course. In the event she was uncertain of her position, she would either call two or more radio compass stations and ask for her position, or, having picked up two or more radio stations and observing their bearings by her radio compass, plot her own position. In this manner she could hardly go wrong and could correct her course readily provided her radio continued to operate successfully.

Incidentally, she could not "fake" her position at the Pole, as the world would soon be advised by radio stations that her reported position was incorrect. Captain Baldwin points out that in the far North, the compass is sluggish and that data for its correction are meager. It is his belief that the only accurate method of proceeding in the polar trips today is with the aid of radio and radio compasses.

Among the stations to which the ZR-1 could report are: Three in Iceland; Spitzbergen, on the 78 parallel; Ingoy, 71 N.; several in northern Russia; our own Army and Navy stations in Alaska; Jan Mayen station on Iceland, and Mijgbugton, 73 degrees N. on the coast of Greenland. Certainly there are sufficient to get cross bearings and correct the course northward. If the stations are equipped with compasses, all the better, but as the ship will have a radio compass, the reception of their signals is all the navigation officer will require.

The ZR-1 is equipped with a type S.E. 1390 transmitter, designed for flying boats like the N.C.-4 which made the record trip across to England. It has modifications, making it gas-proof.

The transmitter uses six 50-watt tubes giving it an input of 300 watts and an average output of 150 watts for wave lengths of 507, 600, 800 and 975 meters on I.C.W. and C.W. communication. It is possible to use this set for radio telephone work but it is not contemplated on the early flights.

The whole set has been tested on the bench with a phantom type having the same characteristics as a trailing wire antennae three hundred feet long, i. e., fundamental wave length 315 meters; 300 microfarads capacity; and 93 microhenries inductance, the resistance ranging through the wave lengths from nine to 13 ohms, giving a radiation of five amperes.

Arrangements will be made for an antenna for use when making a landing. It will be of the loop type fixed between the control car and the two leading wing cars and can be used for communicating when on the ground.

The airship's receiving apparatus will consist of a tuner of the ordinary two circuit type, in conjunction with a six-step amplifier using six S.E. 1444 tubes, three stages radio, a detector and two stages of audio am-

An interesting feature was on the program of Station WOR, L. Bamberger & Company, Newark, N. J., last Wednesday night. Howard Thurston, premier magician of the present day, who is also a recognized authority on psychic matters, delivered a lecture, entitled "Spiritualism," during which he explained some of his new theories pertaining to the "after life," and also told how he happened to arrive at the conclusion that the belief in spiritualistic communication is founded on fact after a long series of experiments. For the past twenty years Thurston has been a relentless anti-psychic, and he has exposed many mediumistic frauds. When he recently announced that he had been converted into a "spiritist" of a new variety he created a sensation.

Radio Reports Prize Fight

(C. Acme Service)

More than two million people listened to the description of the Willard-Firpo fight broadcast direct from the ringside at Boyle's Thirty Acres, Jersey City, N. J., according to the estimate made by the American Telephone and Telegraph Company. The microphone, placed near the ringside, was connected with the apparatus of Station WEAF in New York City, and by long distance telephone lines connected with the transmitting equipment of WCAP, Washington, D. C., and WMAF, at South Dartmouth, Mass. The picture shows the radio equipment being set up on the afternoon before the fight.

(*Concluded from preceding page*)

plification. The long range receiver will be one of new design having a range up to thirty thousand meters using as an amplifier. A universal amplifier of six steps with telephone jacks for using either radio-audio or audio alone in one or two steps will be employed.

The radio compass probably will be installed in the keel, just forward of the control car and may be used for taking bearings on wave lengths from 500 to 30,000 meters. This compass coil is rather unique in that it is of spherical shape and has two sets of coils. In the long-wave reception all the winding are used but in the short-wave reception it is divided into two coils and the variometer effect is taken advantage of.

The airship's name will constitute her radio call, just as the WR-2 before her destruction answered to "WR-2." Lieut. J. H. Gouan, U. S. N., will be in charge of radio, assisted by Chief Radioman J. T. Robertson. The electric power will be supplied by a gasoline-engine driven generator and a 200-ampere hour storage battery, similar in operation to the electric power plant of an automobile. These units will supply current for lighting as well as radio purposes. The battery itself will have sufficient capacity to provide between one and two hours' operation for the radio set in case of a generator break down.

Summer Interest in Radio Is Good This Year

FOR many reasons interest in radio is likely to be maintained this summer to a far greater extent than last year, according to the radio experts of the Bureau of Standards. The maintenance of this interest and of good radio business during the summer depends very largely on the broadcasters and radio dealers.

Two elements of radio receiving sets which have been perfected during the last year or two have gone far to help in making it convenient and satisfactory to use radio receiving sets outdoors. The first of these is the dry battery tube; that is, electron-tube detectors and amplifiers which require only a small dry battery rather than a heavy storage battery to light the filaments. The second improvement is the development of more satisfactory loud speakers which furnish a considerable volume of sound without undesirable distortion. Thus it is possible now with small portable receiving sets which can be purchased or which can be fairly easily assembled, to receive satisfactory radio broadcasting while out camping or boating or making automobile tours. It is a noteworthy fact that exploring parties now take radio receiving sets with them for the dual purpose of furnishing amusement during the evening hours at camp and for receiving time signals with which to check their chronometers.

It must be recognized that radio transmission conditions are not as good in the summer time as in the winter. Transmission range is decreased so that it is not possible to hear the distant stations which can be received in the winter. The presence of atmospheric disturbances often makes it difficult to hear weak signals and reliance must be placed on stations which are near enough and powerful enough to produce loud sounds from the receiving set. Fortunately it is not necessary to rely entirely on distant stations since there are now nearly 600 licensed broadcasting stations in the United States. In fact, about nine-tenths of the area of the country and probably 95 per cent. of the population is within one hundred miles of a broadcasting station which furnishes quite satisfactory service. Therefore, while it has been possible during the winter to receive from any one of a large number of broadcasting stations, the summer decrease in transmission range will not mean an entire stopping of broadcast service for large numbers of people, but only a decrease in the number of stations between whose services they can choose.

There are a number of ways to minimize the interfering noise which is caused by atmospheric and other stray disturbances. At important government and commercial stations certain devices and methods are in use by means of which strays are appreciably reduced and it is made possible to obtain fairly reliable reception during the summer. The apparatus and methods employed at such stations are usually too elaborate to be used at the ordinary broadcast receiving or amateur station. One method which is easily employed and which will be found helpful in reducing certain types of strays is the use of a small antenna. If the ordinary open type of antenna is used its height and length may be reduced and the loss in signal strength recovered by employing a more sensitive receiving set. A coil antenna may be constructed by winding a suitable number of turns of wire with proper spacing on a wooden form about four feet square. In case a coil antenna is used there is some loss in signal intensity but there is an added gain in freedom from interference on account of the directional characteristics of the coil. Thus by rotating a coil antenna to the proper position the directional types of strays may be greatly reduced and a better ratio of signals to strays will be obtained.

Some relief can also be obtained by persons having good amplifiers by using a "ground antenna." This is a long insulated wire run in a shallow trench or on the surface of the ground. The ground wire should be run in the direction of the station from which the most signals are to be received and should preferably be several hundred feet long.

It is also worth while to use various means to improve the sharpness of tuning of the receiving set. Then such interference as is picked up by the antenna will to some extent be filtered out before it reaches the telephone receivers. The receiving set itself should be thoroughly shielded to prevent the tuning coils and transformer windings from direct induction from the source of trouble. Inductively coupled receiving sets should be preferable to single-circuit sets under these conditions. Radio-frequency amplification with sharply tuned inter-stage transformers is also helpful. A well designed regenerative receiving set is also very selective. If the receiving set is one which has a series condenser in the antenna circuit it is sometimes helpful to shunt the set with a high resistance (several thousand ohms) connected between the antenna and ground terminals. This may provide a shunt path for some of the interfering currents and avoid their entrance into the receiving set.

While the increase in the number of broadcasting stations in operation is an important factor in the radio situation this year, a still more valuable feature from the viewpoint of the listener is a very notable improvement in the quality of programs, and other features of operation of broadcast stations. There are now about thirty Class B broadcasting stations operating on individually-assigned frequencies between 1000 and 550 kilocycles (300 and 545 meters). These stations furnish programs of high quality and employ transmitting sets of 500 to 1000 watts power in order to secure the privilege of frequency assignment in this band. The large number of Class A broadcasting stations are also distributed over a range of frequencies from 1,350 to 1,050 kilocycles (222 to 286 meters). A number of these stations as well as some of the Class C stations operating on 833 kilocycles (360 meters) have well-designed transmitting sets and carefully selected programs. The assignment of broadcasting stations to frequencies differing by at least 10 kilocycles, in accordance with the recommendations of the Second National Radio Conference, has resulted in a decrease in interference and an improvement in the quality of broadcast service which is obtainable by the average listener.

Broadcasters Reassigned

Week ending July 14, 1923

The Ideal Portable Receiver

By A. D. Turnbull

PORTABLE receivers seem to have captivated the popular fancy at the present time, partly due to the fact that people desire a receiver that can easily be taken away to the country with them or taken on a trip in a car. In order to be of any great use such an outfit should embody simplicity, ease of tuning, and efficiency to work on a comparatively small collector (antenna).

Under the heading of simplicity the size of the outfit must be small and easily adapted to portability. No one desires to take a set away that takes up half a trunk and needs storage batteries and an expert to operate.

The ideal portable receiver must not have a multiplicity of controls in order to accomplish reasonably fine tuning. Numerous condenser and inductance adjustments only tend to exasperate when signals are quickly desired.

As a loop antenna is to be employed and accommodated to a single tube receiver it is necessary to use the super-regenerative principle, that particular type of circuit giving the best and loudest signals possible on one tube. Unlike most "super" circuits, however, this one does not depend upon large inductance values. Advantage was taken of the principle on which the "flivver" circuits work and an extremely efficient receiver of moderate cost was the result.

The material needed for this portable receiver is: 1 variometer (preferably small size); 1 vernier variable condenser, .0005 mfd.; 1 fixed condenser, .006 mfd.; 1 fixed condenser and variable grid leak, .00025 mfd.; 1 fixed condenser, .001; 1 tube (U. V. 199, or dry cell tube); 1 tube socket; 1 loop antenna; 1 pair phones, 3000 ohms; 1 good vernier rheostat.

If you happen to have any of these parts you can use them, but I want to caution prospective builders to use only the best possible parts. In the choice of fixed condensers it is necessary to get those using mica dielectric. If paper insulated ones are used the difference in capacity in damp weather and dry weather will be so great that the set will not operate at all. Also do not use a condenser whose capacity you can change by squeezing. It is best to pay the few cents more that the best will cost than to buy inferior goods and then be disappointed in the results. In purchasing a rheostat be sure to get one that is capable of fine adjustment. For this reason it is best to get the carbon pile type, as their range of adjustment is extremely large, and very fine adjustment can be had by careful manipulation.

The entire set easily can be accommodate in a cabinet 10 inches by six inches by six inches. So get a panel that size and drill it for the variometer, variable condenser and rheostat, mounting them as your fancy suits you, but bearing in mind that as the variometer will be used the most it should be placed so as to be handy.

Shield the entire panel carefully with copper screening or foil and ground it to the minus side of the A battery. Watch out when shielding that your jack is clear of the shielding, as I managed to short my shielding on the jack, and wondered for some half hour what could possibly be the trouble.

When the panel is drilled, and everything is in readiness, connect up the instruments as shown with tinned bus bar wiring, using varnished cambric tubing on all of the leads. This is a necessary evil in all portable sets, especially where they are to be contained in small cabinets as the wiring is necessarily close and no chance should be taken with accidental short circuits due to jarring. When connecting the fixed condensers in the circuit take the precaution to mount them far enough from the shielding. If they are mounted too near the shielding they will add stray capacity to the circuit and the set will howl and act in general like a "mad dog" instead of a docile receiver.

No instructions are given as to the construction of a loop as numerous articles have appeared in RADIO WORLD on this subject.

The B batteries can either be carried as part of the set, or separately, depending upon the amount of voltage that is desired, always keeping in mind that the volume depends directly upon the voltage in this circuit. It will work fine on 22½ volts, but best results are to be had when 45 or 67½ volts are used.

After making sure of your connections and going over them several times before inserting your tube in the circuit, turn the filament on. Place the variometer at 50° and swing the loop in the direction of the station desired. When the signal or carrier is heard reduce the filament current and tune the variometer. During the first operation of the set, the high-pitched whistle or scream of the "super" will be noted. This should be varied until it is almost too high to hear, by varying the grid leak capacity. After it is set, it will be noted that it will vary slightly with the tuning of the variometer,

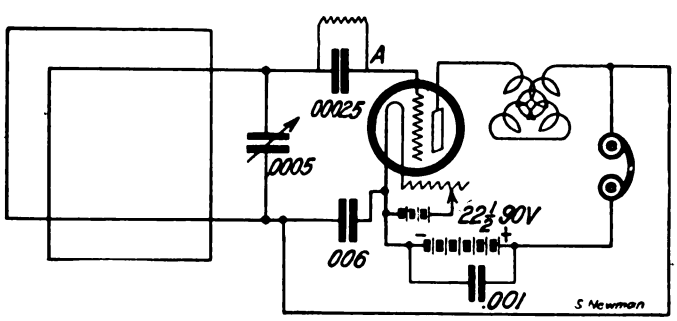

Diagram of a loop set employing the "flivver" principle that will work admirably on a comparatively small loop. Care should be taken in the construction and placing of the condensers.

and that the signals will always be the loudest when the pitch of this whistle is highest. This whistle should always be present, as if it stops, the circuit is not working correctly and the grid leak should be re-set until it appears.

The last operation of the set is clearing out the signals by means of the vernier control of the variable condenser. If any interference is noted it can easily be tuned out by swinging the loop, but in that case the entire set should be re-tuned.

Extremely long distance is possible with this loop set, and it is not an exaggeration when I state that I have consistently logged WDAR and KDKA on a 3-foot loop from Nova Scotia, which is a distance of 1,000 miles. It is simple to construct and tune and the dials can be set for certain stations and the same station will always come in on the same settings, regardless of anything else.

As a final note I again want to caution builders to be very careful in their construction, especially in the connection of the instruments, keeping all the leads separated and cross them at right angles. Do not vary one bit from the diagram and expect to get any results, as the circuit is simplified as it is.

A Long Distance Sensitive Crystal Receiver

By Richard B. Wilbur

FOR radio fans who do not want to put much money into a radio receiving set, and who wish to get long distance stations, herewith are the details of a very sensitive crystal receiver, using an ordinary crystal detector. This set, if properly built and operated, will get results that will be surprising. The writer has a set of this kind that has received a station at a distance of 1,410 miles with plenty of volume and clearness of reception. This set is the tube's only rival.

The parts needed to construct it are as follows: 1 6½"x12" panel (any kind); 1 23-plate variable condenser; 1 .002 mfd. phone condenser; 2 switch levers; 18 switch points; 4 switch stops; 2 3" dials with knobs; 1 crystal detector (ball and socket type is best); 1 unmounted galena crystal; 1 empty shaker salt box (3½" inside diameter, 6" long); 1 3" rotor ball; 1 ¼"x6" tube for rotor shaft; 1 8 oz. spool of No. 22 DCC magnet wire; 1 ¼" board, the same size as the panel; 2 pieces of flexible wire, 6" long (leads for rotor).

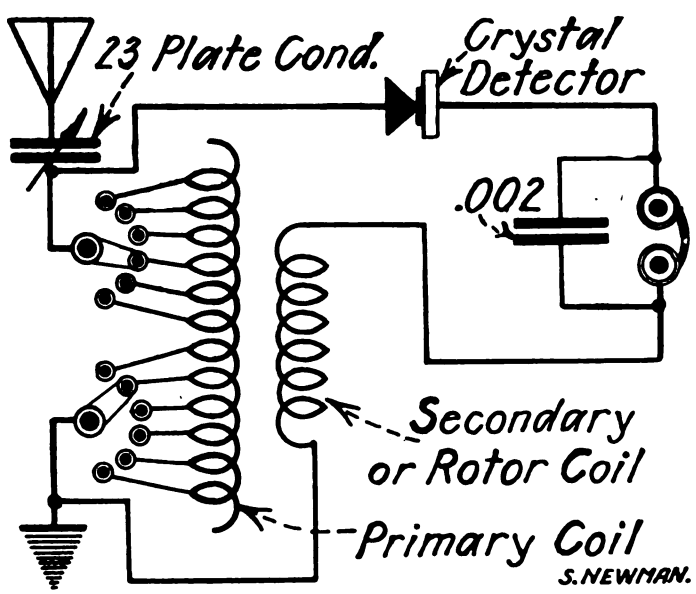

Fig. 1. Hook-up for Wilbur's long distance sensitive crystal receiver.

The total cost of these parts ought not to be over $6.50.

Use a variocoupler that will tune from 150 to 650 meters. It is best to make one yourself and it's a trifle cheaper than buying one—and it will be more efficient.

To make a coupler take the empty shaker salt box which will measure 3½" inside diameter, and 6" in length. Measure to the center of the box and make a mark. Now get a stiff piece of paper ½" wide, and measure around the outside of the box, commencing at the center mark. Get the exact diameter of the outside of the box, fold the strip of paper and cut. You now have one-half the diameter of the box. Take one of these strips and place one end on the center mark, hold tight on the box and mark the other end of the strip. Now then you have the marks on the box where you are to make holes for the rotor shaft.

In winding the primary coil, first make two small holes in the box ¾" down from the top, then take the wire and weave it through the two holes a couple of times to anchor it, and leave about seven or eight inches for a connection. Now start winding. Wind on 20 turns of wire (clockwise), then take off a 6½" twisted tap, wind on 30 more turns of wire taking off a twisted tap every fifth turn, and shorten each tap ½" each time; also stagger each tap a little, so that one will not be directly under the other. You have now wound the tube to the center, where the holes are for the rotor shaft. Leave a space ½" wide and angle across between the shaft holes and start to wind again, wind on 50 more turns of wire taking off a twisted tap every fifth turn. Take off the first tap after crossing the ½" space in the same position as you took off the first one in the beginning of the winding, and stagger them the same way. When the last tap has been taken off, cut and anchor the wire. The primary coil is now wound, so scrape off the cotton covering of the ends of the twisted taps.

The three inch rotor form is to be wound next. It should hold about 76 turns of wire. Wind each side of the rotor in the same direction, and solder the two wires together that meet in the center of the rotor. An inch of wire should be left at the beginning of each winding, so that you can connect the flexible leads.

Take the 6" shaft and cut a slot in it about 2" from one end. This slot will be for the flexible leads to pass through.

After this is finished, insert the rotor into the center of the primary coil and put the shaft through it, with the end that has the slot in to the back side. The two 6" flexible leads should be next inserted into the slot in the shaft and started out the end. Solder the flexible leads to the ends of the rotor windings and pull the slack out of the flexible leads. The variocoupler is now completed.

The panel should be drilled next. A sketch of the panel is here shown. Use a ruler in measuring each hole to be drilled so that when the set is finished it will look neat. The variable condenser should be placed in the left center of the panel, with the variocoupler in the right center, the two switches (one above the other) and the detector in the center, between the condenser and coupler. The antenna and ground binding posts go in the upper left side, and the phone binding posts in the upper right side. The .002 condenser should be used to measure the spacing of the four binding posts. The .002 phone condenser is fastened on the panel with the phone binding posts.

After the panel has been drilled, the next thing to do is to fasten the twisted taps of the coupler to the switch points. Fasten the first turn of wire on the coupler, to the first switch point of the upper switch. Commence with the switch point on the left. The first eight twisted taps go to the upper switch and the other 10 go to the lower switch. Fasten both sets of taps the same way and in the same direction. After this is finished, fasten the baseboard to the panel with four small screws. Fasten the variocoupler to the baseboard next. Be sure that enough of the rotor shaft goes through the panel so that you can fasten the dial to it. It is best to put the dial on the shaft, then fasten the coupler to the board. By doing this you can easily fasten the coupler so that the dial won't wobble when it is turned. Fasten the variable condenser to the panel next, then the detector, and binding posts. You are now ready to wire the set. Herewith is a sketch of the hook-up for this set.

(*Concluded on next page*)

Digitized by Google

(Concluded from preceding page)

Fasten a wire to the antenna binding post and run it to the back side of the variable condenser where you fasten it to the connection of the rotor plates. Fasten another wire to the stator plate connection of the condenser and run it to the upper switch lever and fasten. Fasten another wire to the stator plate connection of the condenser and run it to the crystal side of the detector and fasten. Attach another wire to the cat-whisker side of the detector and run it to the upper phone binding post and fasten. Run another wire from the lower phone binding post to one of the flexible rotor leads of the coupler and solder it. Solder another wire to the other rotor lead and run it to the ground binding post, and from here over to the lower switch lever and fasten it. The wiring is now completed and the receiver is ready for use. A cabinet can be made for this set at a small cost and will improve the looks of it.

The best kind of antenna to use with this set is a single wire not over 100 feet long, 35 feet or more in height, with about a 35 foot or more lead-in depending on the height that it is erected.

A good ground should also be used with this set. The best kind is a five foot piece of lead or zinc pipe driven in the earth with a No. 14 wire soldered to it and run to the receiver.

The writer has received stations up to 50 miles without a ground connection to the set, and has also received stations up to 35 miles without an antenna connection to the set. So you may know that this set is very sensitive. But you *must have patience* to operate it successfully. Don't give up when you first sit down to it to tune in if you don't hear anything. It may be because there isn't any one on the air. Wait until you are sure there is someone broadcasting. Use the most sensitive unmounted galena that you can buy. The reason why the unmounted is best, is because it has six surfaces to it where the mounted only has one, and it is much cheaper, too. The writer will be glad to help any one with suggestions pertaining to this set.

Herewith is a list of stations that has been heard in two weeks time with a set of this kind. The distances are also given:

WHAZ—Troy, N. Y.	1,322	Miles
WLW—Cincinnati, Ohio	690	"
WWJ—Detroit, Mich.	730	"
WCX—Detroit, Mich.	730	"

I have not listed the stations under 100 miles for it would take up too much paper to write them on.

Broadcasting Pres. Harding's Speech in Texas

FORT WORTH, TEXAS.—Future possibility of carrying the human voice over a wide area during political campaigns by means of a battery of broadcast stations connected by long-distance telephone lines was demonstrated recently when Station WBAP of the Wortham-Carter Publishing Company here broadcast into thousands of Texas and southwestern homes the speech of President Harding, made 700 miles away at Station KSD, at St. Louis.

This remarkable feat was accomplished through the Fort Worth "Star-Telegram," and its success assured on account of the co-operation given by F. M. Corlett, manager of the West Gulf Division of the American Radio Relay League, and a League member at St. Louis.

As static and other atmospheric conditions would not permit the direct reception of the President's speech by listeners in the vicinity of WBAP they would have been unable to hear the address at all had it not been for the arrangement by which his words were received at the station of a St. Louis member of the American Radio Relay League, turned into a loud-speaker and finally into a long-distance connection with the Texas newspaper's radio room, where they were amplified for WBAP.

The idea of sending out through the air an address by means of several stations broadcasting simultaneously by the aid of toll telephone lines, or similar connections, has been frequently visualized by far-seeing radio men, yet never has it been attempted over so great a distance or with the same result as in this case.

According to the management of WBAP, the "Star-Telegram" local telephone exchange was jammed with long-distance calls of appreciation from enthusiastic listeners who had been informed by broadcast and through its news columns of the spectacular side of the feat.

Members of the 101st Signal Battalion, New York National Guard, in camp at Peekskill, listening to broadcasting by means of a French army field set. The members of the battalion are given a thorough course in radio which has supplanted field telegraph and telephone to a great extent in the army because of its portability and ease of control.

(C. Kadel and Herbert)

Ivan Andre, well-known artist of England and France, finds that radio concerts are a great aid to his inspiration. At present he is in this country, executing a number of miniatures and landscapes. His only hobby outside of painting is radio and his portable set is always with him. It is a three-tube reflex using U.V.199 tubes with a small loop antenna. One is reminded that there is no accounting for the tastes and idiosyncrasies of temperamental people like artists and musicians. When we catch an office boy whistling shrilly and doing a piece of work at the same time we are prone to think that his temporarily divided mentality isn't especially good for the work—but he may whistle fine. The right program received by radio doubtless is soothing.

(C. International Newsreel)

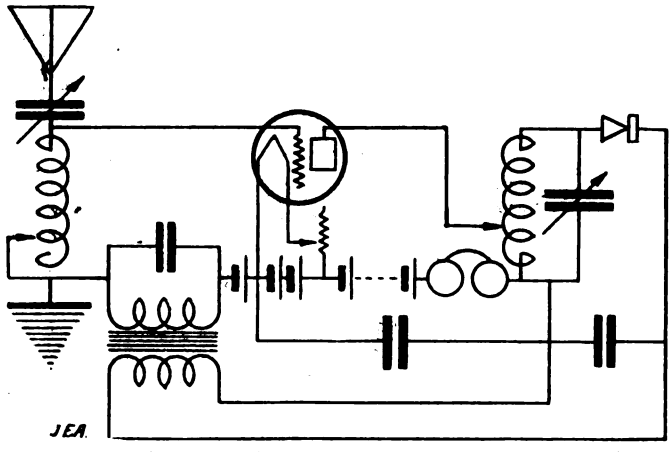
The English Parliament recently were Signor Marconi's guests at a demonstration which took place at the Chelmsford and Ongar wireless stations in England. This is an unusual photograph of Marconi, inasmuch as it shows him with a head set on. On the left is Godfrey Isaacs, M.P., and on the right is Gratton Doyle, M.P., taking great pleasure in listening in on Marconi's portable receiver located in the limousine.

A Simple and Satisfactory Regenerative Reflex Receiver

By J. E. Anderson, M. A.

SIMPLICITY of control is one of the main characteristics of a reflex receiver. In many of the circuits there is but one variable while in others there are only two. None of these simple circuits is regenerative, and for this reason they are neither as selective as they might be nor is the volume of output as large. It is ordinarily believed that if they are made regenerative they become too difficult to manipulate; but this is not necessarily so. By the sacrifice of a little simplicity a reflex circuit may be made regenerative, and the regeneration may be held under perfect control. Only one or two additional controls are necessary.

The writer has tried out numerous reflex regenerative circuits with a view of finding a simple and satisfactory combination. The trouble encountered was not in finding good circuits but in selecting the best out of the many good circuits tried. Many of them seemed equally good, some excelling in sensitivity, some in selectivity, and others in simplicity of control. The



Anderson's simple and satisfactory regenerative reflex receiver hook-up.

circuit shown in the accompanying diagram seemed best to meet the requirements.

This is a single circuit tuner, single tube reflex that is made regenerative by varying the inductance, or more accurately the reactance, in the plate circuit. It may be operated in three different ways. In the first place, as a simple regenerative receiver, in the second as a simple reflex, and in the third as a regenerative reflex. If it is desired to use it as a simple regenerative circuit all that is necessary is to lift the catwhisker from the crystal and tune the plate until the proper amount of reaction is secured. When it is used in this manner the circuit is extremely selective. If it is desired to use the circuit as a simple reflex the catwhisker is adjusted for maximum sensitivity and the secondary of the plate auto-transformer is tuned to the desired frequency. The portion of the coil that is included in the plate circuit is then adjusted to a value such that the circuit will not oscillate. For short wave lengths only a few turns are necessary, while for the longer broadcasting wave lengths the entire coil may be required. If it is desired to use the circuit as a regenerative reflex the secondary of the auto-transformer is tuned accurately to the frequency desired. Then the plate inductance is increased until the circuit will oscillate, when a slight detuning of the condenser will just stop the oscillations and bring the signals to the desired intensity, or to the maximum intensity obtainable. If the circuit will not oscillate, the inductance in the grid circuit is also increased, and the plate variables readjusted. It may be necessary to change all the four variables at the same time; that is, the two variable condensers and the two variable coils, in order to get best results. Usually a very large value of inductance is needed in the grid circuit and a comparatively small value in the plate circuit.

The inductance coil in the grid circuit should not be less than 75 turns on a 3.5 inch tube or the equivalent. This should be capable of variation in steps of two to five turns. The condenser in the antenna circuit should not be larger than .0005 mfd. A .00025 mfd. condenser would be preferable if it is available. The inductance in the plate circuit coil should be about 60 turns on a 3.5 inch tube, or its equivalent, and this should be tapped every five turns. The condenser across this coil may be one of .0005 mfd.

The by-pass condenser in the primary of the audio-frequency transformer may be omitted if desired. If it is used it should not be larger than .001 mfd., because it directly affects the tuning of the plate circuit. The by-pass condenser in the secondary of the transformer may also be omitted as the safe-capacity of the leads is about sufficient. However, if it is used, it should not be larger than .0005 mfd. Both of these by-pass condensers, if too large, will also by-pass the high audio-frequencies to an appreciable extent. The effect is a general lowering of the tone of music and speech. If the signals are too shrill, that is, if the high audio-frequencies are too pronounced, these condensers may be used to reduce the distortion and render signals of a more pleasing tone.

Sometimes it is not possible to cause the tube to oscillate, especially for the higher broadcasting wave lengths, even if large inductances are used both in the plate and the grid circuits. Some tubes oscillate much more rapidly than others, due to greater inter-electrode capacities. When the tube will not oscillate because these capacities are too small, it is necessary to introduce additional reactance between the plate and the grid circuits. This may take any of the customary forms used to secure regeneration, but it does not need to be variable unless desired, as sufficient variation can be secured in the two variable coils or the two condensers.

Just a few words will be said about the performance of this circuit. It was first tried out during a time when the local broadcasting stations were silent. But the traffic in the ether was really heavy. Many medium distance stations were brought in, and a surprisingly large number of small local stations were "discovered." But since most of these stations had never been heard before on that antenna, it was not much of a test of the circuit. However, when WOR opened up it was no longer necessary to wear the head phones; for the signals were so loud that they could be heard all over the room. It was more than the little dry cell tube used could carry, and consequently the quality of the signals was very bad.

Latest Radio Patents

Receiving System for Electric Waves

No. 1,457,009: Patented May 29, 1923. Patentee: Lucien Levy, Paris, France.

In the specification of patent application Serial No. 249,572 filed August 12, 1818, the applicant has described a system of electric transmission at a distance, applicable to wireless telegraphy and telephony and comprising a special transmitting station device and a special receiving station device.

In this patent it was specified that this receiving station device could be combined with a local generator permitting it to receive the ordinary emissions of the continuous wave stations under sufficient conditions of selectivity in spite of the disturbances of spark stations or atmospheric parasites.

Fig. 1.

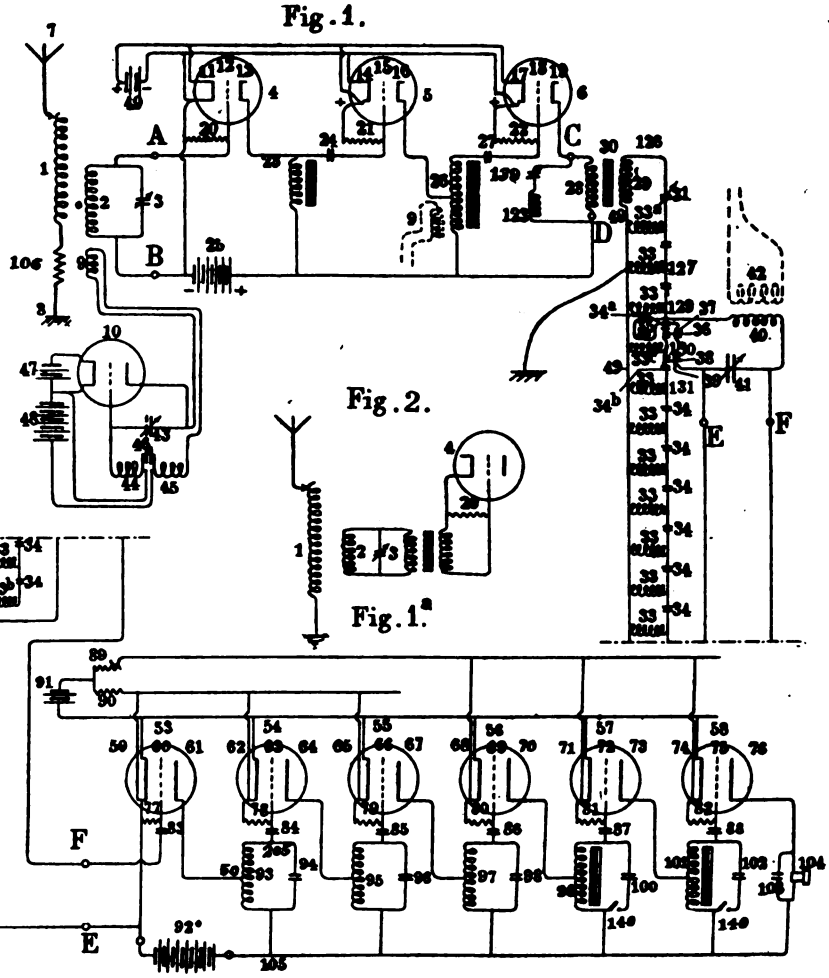

Fig. 2.

Fig. 1a.

Circuit diagrams of Levy's improved system for receiving electric waves.

The present application has for its object an improvement made in the receiving system described in the original application of the applicant in the case of its application to waves emitted by ordinary stations, for the purpose of obtaining a more complete selectivity and a greater protection against atmospheric parasites.

These improvements consist in:

1. A special method of secondary selection based on the original principle described and comprising also various complementary operations intended to ensure efficient working of the system in all cases, even when the parasitic disturbances or confusion are very intense.

2. Arrangements which permit of the practical carrying out of the improved method and ensuring very great sensitiveness of the system.

The present improved method comprises, broadly, the following operations consisting:

1. In producing in the primary detecting selector circuits, before the first detection, beats of adjustable amplitude and of adjustable ultra-acoustic frequency (of the order for example of 10,000 per second) between the currents induced in the circuits by the oscillations of the receiving antenna and the current which is induced by a local generator of high frequency.

2. In amplifying and then detecting these beats in a detecting amplifier of high frequency.

3. In separating the numerous periods of current of ultra-acoustic frequency furnished by the detection of the beats of the continuous wave, from some periods of limited amplitude and very small in number, (one or two furnished by parasites) and from the currents of low frequency coming from the succession of the parasites: this selection taking place in a secondary selector the working of which, is based generally on the known phenomena of propagation of electric waves of systems with capacities and self inductors distributed in a relatively small number of elements.

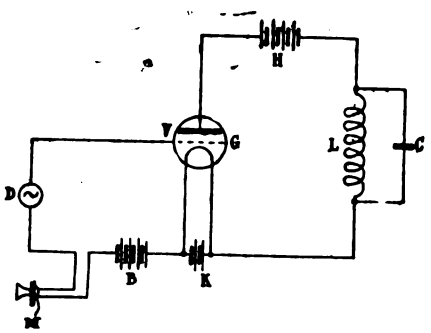
4. In amplifying the selected currents of ultra-acoustic frequency and in transforming them into current of acoustic frequency by causing them to beat with a local current of ultra-acoustic frequency and then in detecting the beats obtained.

5. In effecting a selection on the acoustic frequency.

Modulated Wireless Signaling System

No. 1,455,849: Patented May 22, 1923. Patentee Norman Lee, London, England.

This invention relates to modulated electric signaling systems and particularly to wireless signaling systems.



Lee's modulated wireless signaling system.

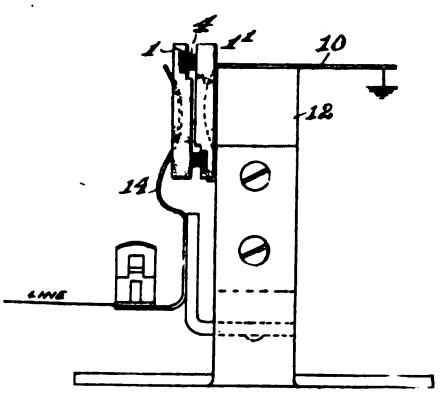
The principal object of the invention is to provide an amplifying appliance wherein the high frequency output of an amplifying power valve energized by a suitable source of oscillating current is modulated by causing the separately produced modulating potentials to vary the potential of the grid of the power valve about a certain negative value and thus to vary the high frequency output of the valve.

Electrical Protector

No. 1,457,249: Patented May 29, 1923. Patentees: G. W. Janson, Brooklyn, N. Y., and L. H. Rovere, Richmond, N. Y.

This invention relates to protective devices for electric circuits, commonly referred to as lightning arresters.

The purpose of the present invention is to provide an arrester in which the air-gap is very accurately determined and definitely maintained and wherein no mica or other separators are interposed between the arcing surfaces so that an inspector can readily detect any attempt to alter the thickness of the air-gap. We furthermore provide for a direct positive contact between the electrodes whenever the arcing continues beyond a predetermined interval, thus avoiding the expense of providing fusible inserts as well as any uncertainty which may be occasioned by relying upon a connection of fusible metal.



Janson's improved device for protecting electric circuits.

Answers to Readers of Radio World

Is amplification without tubes possible? Is it practical? Is any firm making instruments of that sort?—Joseph Shannon, 702 Seventh Avenue, New York City.

Amplification is possible by the use of magnetic amplifiers, utilizing the microphonic vibration principle. They are not practical because of the harsh sounds that they make. No firms that we know of make instruments of this sort. There is no market for such apparatus, as the present tube amplifiers are much more efficient.

* * *

What set would you consider best for one using not more than three tubes? Will the 22-turn coil and 43-plate condenser used in the antenna circuit of Mr. Shult's set, described in RADIO WORLD *for February 17, be of any value in other circuits? Can a .001 variable condenser with vernier be used in place of an .0005 variable condenser? Will connecting four .001 fixed condensers and one .001 variable condenser in parallel as per enclosed sketch give me a useful capacity of .005?—Jesse I. Seward, 1 Clinton Street, Palmyra, N. Y.*

Would suggest that you use a three-tube reflex circuit, such as the D7 Reflex, using a crystal as a detector. This will allow you to get the most out of three tubes if you take extreme care in the construction and use the best apparatus. You can use the coil and condenser you mention in other circuits that call for a coil of this size. The condenser can be used in any circuit. You can use a .001 variable vernier in a circuit that calls for a .0005 by using half of its capacity. The arrangement of condensers that you suggest would allow you to get a useful capacity of .005.

* * *

In RADIO WORLD *for April 14 you published a circuit by Arthur S. Gordon. I have constructed this circuit and have had good results when I use the detector, but when the amplifier is plugged in the set seemingly goes dead. I have checked the diagram with my set and find that it is absolutely correct. What can my trouble be and how can I remedy it?—William Oakes Morris, 197 So. Whitney Street, Hartford, Conn.*

Suggest you test your amplifying transformers. It is quite evident that, as you have tested out your circuit and found it absolutely correct, one of the windings must be blown. Test each one out independently by means of a dry cell and a pair of phones. If you do not hear a click when the circuit is made and broken you will know that you have a burnt-out winding, or that one of the windings is damaged in some manner.

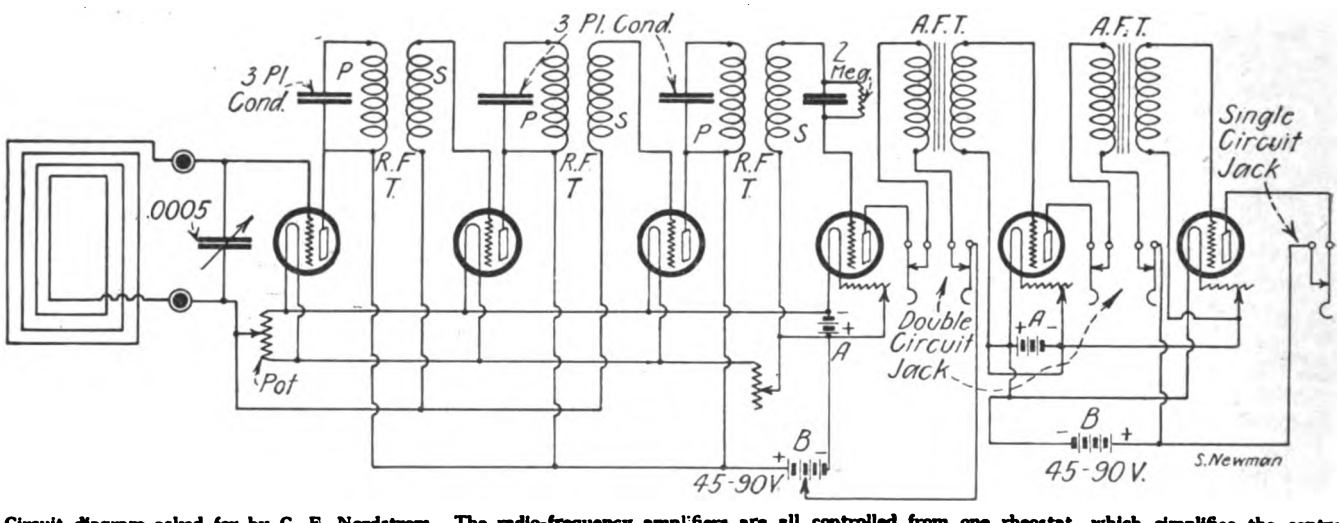
* * *

I intend building a portable set to take away to camp with me. Is it possible to use the flashlight cells to light a six-volt tube if I use six cells, three in series and three in parallel?—Jacob Winslow, 374 Elm Street, Boston, Mass.

You should be able to light your tube by the use of the cells you mention, but you have the wrong idea in regard to the connections. You should hook up two sets of three in series and put them in parallel with each other.

* * *

Kindly publish a circuit diagram of a three-stage radio-frequency, detector, and two-stage audio-frequency set, with a loop antenna and separate rheostat for each tube in the audio-frequency tubes and 3 plate condensers across the radio-frequency transformers.—C. E. Nordstrom, 3224 18th avenue, South, Minneapolis, Minn.



Circuit diagram asked for by C. E. Nordstrom. The radio-frequency amplifiers are all controlled from one rheostat, which simplifies the controls considerably. Separate A and B batteries are furnished for the audio-frequency and radio-frequency tubes to prevent any chance of trouble due to radio-frequency currents leaking through to the audio-frequency tubes. This is the best method of procedure in a set of this type. Tuning is done by means of the condenser shunting the loop.

The circuit you wish is published herewith. It is necessary when constructing a circuit of this type to keep your leads separated and the battery leads apart. Two sets of batteries are furnished for both the radio-frequency and audio-frequency circuits to prevent any trouble due to leakage from one circuit to another. A coupler is not necessary when a loop is used.

* * *

I noticed the term "phantom circuit" used in connection with the measurements of various circuits in experimental work. What does the expression signify?—Robert Mackay, Box 14, Sheepshead Bay, L. I.

In laboratory experiments it is not advisable to use regular antenna and ground circuits in conducting all kinds of work; therefore resistances and inductances are used which measure exactly the same as would the regulation antenna and ground system. Experiments are conducted in this manner. Thus one is able to find out how different experiments work out without actually using the regulation system. When they are working in this manner they are using "phantom circuits."

In a paper recently presented before our local radio club one of the talkers made mention of the fact that the windings on a coupler of a radio set should be made with the same size wire on both primary and secondary. I have made a coupler, but have used 20 DCC wire on the primary and 24 SCC on the secondary. Should I rewind it? Will it give me better results?—Lawrence Houston, Palm Cottage No. 6, Florida.

The common method of procedure is to wind the same size wire on both the primary and secondary of the couplers, but it will not detract from your set by having different size wire on both windings.

* * *

I recently built the circuit described by George W. May in RADIO WORLD *for Feb. 17 and have had wonderful results. Can I turn this receiver into a reflex set? If so, will you please give me a diagram and constructional data for doing it.—Edward Walter, 5624 Locust Ave., Kansas City, Mo.*

You can use some of the apparatus for a reflex circuit, but turning the same circuit into a reflex is impossible. We refer you to RADIO WORLD for Feb. 24 and March 3 for reflex circuits.

* * *

Is it possible to utilize a battery charger for filament current without using a storage battery? How will I connect it?—Harry Gilbourne, Yard Street, Freehold, N. J.

You cannot do what you mention. You would blow your tubes. A battery charger is not meant for that kind of work. It is designed for charging storage batteries alone, and cannot be used for anything else. The use of any rectifier feeding directly from alternating current would produce a very disagreeable hum in your tubes.

* * *

I am desirous of building a radio-receiving set that will enable me to clearly get long-distance stations. What is the most advisable circuit to use that will allow me to accomplish this?—Dr. B. Kahn, First National Bank Building, Winters, Texas.

We would advise the use of a reflex circuit for the purpose you name, with radio-frequency, detector and audio-frequency set as a second choice. Numerous circuits of both these types have appeared in back numbers of RADIO WORLD.

Origin of the SOS Call

By Jack Binns

WHAT do the letters SOS used by ships at sea as a distress call stand for? That is the question which I have been asked a thousand times, says Jack Binns in the New York *Tribune*. The answer to it is simple enough, but in view of the general aptitude to assign a catch phrase to any arbitrary group of letters, a simple answer will not suffice the average person. In this case the letters are associated with the cry "Save our souls!" so far as the public is concerned, while the call CQD, which it superseded, meant "Come quick, danger!" to the layman.

As a matter of cold fact, neither of these two phrases is correct. Unfortunately, it is the truth that both groups of letters were adopted as a matter of expediency and not because of their peculiar susceptibility to dramatic interpretation. The original CQD was arrived at by the ordinary process of evolution in the detail work of communication, while SOS was an arbitrary adoption of the first international radio telegraph convention.

The story of the distress call has never been adequately told, and in view of the large number of questions that have been raised on the point I am going to outline in this article the history of the famous calls.

When wireless telegraphy was first placed into commercial use the ordinary telegraph and cable systems had been in operation several years and had reached a high state of development. The operation of the latter systems was governed by an international convention which periodically laid down rules to meet necessary operating requirements.

Among these rules was a series of double letter symbols which were used by operators to facilitate the working of special circuits, and these symbols invariably incorporated the letter Q because it is one of the least used letters in the alphabet, and in the Continental code its dots and dashes are distinctive. In these various groups there was the signal CQ. This was used on telegraph lines where more than one station was on the line, and it meant that the operator sending the call wanted every station along the line to listen in to what he was about to say.

Now most of these operating symbols were adopted by Marconi's new company when it began commercial operation at sea in the year 1902. The call CQ particularly adapted itself to wireless use, because any ship hearing the call would answer and thus establish communication with the ship making the call.

As the system gradually developed there were a number of minor emergency calls made and it was quickly observed that the call CQ was not of sufficient distinction for emergency purposes. As a result of these experiences the following general order, known as "Circular No. 57," was issued by the Marconi company on January 7, 1904:

"It has been brought to our notice that the call 'CQ' (all stations), while being satisfactory for general purposes, does not sufficiently express the urgency required in a signal of distress.

"Therefore, on and after February 1, 1904, the call to be given by ships in distress or in any way requiring assistance, shall be 'CQD.'

"This signal must on no account be used except by order of the captain of the ship in distress, or other vessels or stations transmitting the signal on account of the ship in distress.

"All stations must recognize the urgency of this call and make every effort to establish satisfactory communication with the least possible delay.

"Any misuse of the call will result in instant dismissal of the person improperly employing it."

This is the exact wording of the famous general order as issued. The original is now framed, and exhibited as part of the important archives of the Marconi company. It was superseded in July, 1908, by the adoption of the call SOS as a distress signal by the International Radio-Telegraphic Convention, which sat in Berlin. As this convention was not completely ratified by all of the nations represented for at least a year, the call CQD remained in force sufficiently long enough to be used in the first major sea disaster where wireless played an important part.

The call SOS is purely arbitrary in its grouping of letters and was chosen because of the unusual combination of dots and dashes which make it distinctive above all other calls. It consists of three dots, space, three dashes, space and three more dots.

Do You Remember When—

A receiver consisted of a coherer and you used to hold your breath when it clicked?

You first made your tuning coil, laboriously winding a rolling pin with wire, connected it to a galena or carborundum detector, and then tuned for Navy, and boasted about it for a week?

You used to try and copy some of the crack operators in the Navy and you covered sixteen sheets with two letters, a word, and then finally a whole sentence?

You first heard a signal over another fellows "audion?" And then for nights you used to lay awake and plan ways of making enough money to get one?

You used to copy Arlington press and weather and pride yourself on the fact that you never missed a word?

You got so used to hearing the weather report that you could tell what was coming and write it down before it was sent?

You blew out your first tube?

You went down to the Navy yard for your license? Gosh, but a radio officer can make you nervous!

The Farmer Informs the City Feller

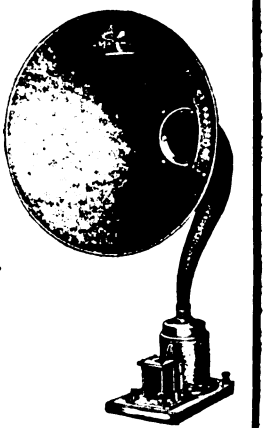
A PARTY of city dwellers, returning from an automobile trip into the Adirondacks the evening of July 4 began to discuss the Shelby financial fiasco. It was after 8 o'clock and they were naturally curious about the outcome of the fight. Passing a farm house, one of the men in the party saw a radio antenna running from dwelling to barn and he suggested that they ask the farmer for the latest news on the fight.

The farmer was caught as he came in from the barn. He calmly heard their question as though it was the most natural thing in the world that he should be asked the outcome of a fight in Shelby, Montana.

"Dempsey won on points," the farmer laconically answered.

The radio story of the fight, broadcast by WGY at Schenectady, N. Y., gave the farmer the news as quickly as it arrived in the offices of great metropolitan newspapers.

MAGNAVOX
Radio Products



R2 Magnavox Radio The Reproducer Supreme

The Utmost in Sound Amplification

Where the reproduction of broadcasted programs is desired in large volume, the Magnavox Reproducer R2 should be used.

Thanks to the Magnavox (electro-dynamic) principle of construction, this result is secured with minimum electrical energy.

Without Magnavox equipment, no Radio receiving set is complete.

Magnavox R3 Reproducer and 2 stage Power Amplifier . . . $90.00

R2 Magnavox Reproducer with 18-inch curvex horn: the utmost in amplifying power; requires only .6 of an ampere for the field $60.00

R3 Magnavox Reproducer with 14-inch curvex horn: ideal for homes, offices, etc. . . . $35.00

Model C Magnavox Power Amplifier insures getting the largest possible power input for your Magnavox Reproducer.

AC-2-C, 2-stage, $55.00
AC-3-C, 3-stage, $75.00

Magnavox Radio products can be had of good dealers everywhere. Write for copy of our new booklet.

$3,000,000 Radio Purchase

GIMBEL BROTHERS, of New York City, it was announced last week, have closed a deal with the Radio Corporation of America for the purchase of 20,000 Radiola R. C. receiving sets, manufactured by the Westinghouse Electric & Manufacturing Co., over 60,000 of which are now in use in the United States. The purchase price was not divulged, but it was reported that the value of the merchandise, at present nationally established list prices, is about $3,000,000.

Station WOR Awards Prize to Dr. Gildersleeve

STATION WOR, owned and operated by L. Bamberger & Co., Newark, N. J., recently offered a prize for the photograph showing the best and most decorative arrangement of a radio receiving set in the home. Many amateurs entered the contest, some of them submitting three and four photographs. The prize, which is a hand-colored enlargement of the winning photograph, has been awarded to Dr. Donald M. Gildersleeve, 169 Prospect Park West, Brooklyn, N. Y., for the picture of his set used as an illustration on page 13 of RADIO WORLD for July 21, 1923.

A Fixed Crystal Detector

THE Grewol detector, distributed by the Randel Wireless Company, Newark, N. J., takes the crystal detector out of the group of adjusting instruments, which the fan has to learn to operate. It performs all the duties of a detector, but requires no more attention than a fixed condenser. The Grewol detector comes to the consumer already set and fixed so that the adjustment is vibration and jar-proof. At the factory the most sensitive spot on the crystal surface is found, and the cat-whisker is secured so as to stay exactly on this spot. A glass cover fits snugly to keep out moisture and dust. This detector on a set can be forgotten. The makers claim that it will continue always to be as sensitive as the day it was purchased because the adjustment cannot be "lost."

De Forest Company Again in the Courts

PAPERS were served on July 17 on the DeForest Radio Telephone and Telegraph Company, of Jersey City, N. J., in a suit brought by the Wholesale Radio Equipment Company of Newark, N. J.. The plaintiff wants $125,000 for breach of contract, alleging that on Oct. 6 last it signed a contract with the DeForest company by which the plaintiff company was to handle the defendant company's products for two years.

The DeForest company recently notified the Newark concern that the contract would be canceled on June 23. The plaintiff company had $7,500 worth of the defendant company's products on hand, it said, the value of which was depreciated by the sale of the defendant company's products by the defendant company to other agents in the same territory at a lower price.

Radio Trade Notes

W. L. Armitage, 647 Yonge St., Toronto, Ontario, Canada, would like exclusive agencies for Canada.

The Blue Ridge Electric Company, 709 National Bank Bldg., Charlottesville, Va., has been organized to act as manufacturers' agent for electrical appliances and supplies.

Every City Should Have Its Broadcasting Plant

SOME months ago there appeared in RADIO WORLD an article about the new broadcasting station to be built and operated by the City of New York. This article attracted a great deal of attention.

RADIO WORLD is now starting a campaign for the purpose of interesting the city fathers of all the good-sized American municipalities in a plan by which each city shall have a municipal broadcasting staton of its own. In this way the message of radio will reach the homes of millions of Americans who are not now owners of radio sets, and in the near future should lead to millions of new sales of radio sets that would not otherwise be made.

RADIO WORLD is getting in touch with the city authorities in thousands of towns throughout the country in the effort to make known its plan, which is a most comprehensive one and shows how it can be operated for the benefit of present local radio fans and fans-to-be.

By the way, a nominee of either party who would come out on a platform, one of the planks of which would be "Our city should have its own municipally operated broadcasting station," undoubtedly would be a popular candidate among local voters.

The more municipal broadcasting stations that are organized throughout the country on the order of New York City's broadcasting station, the better it will be for all owners, manufacturers, distributors, dealers, and the art, science and business of radio generally.

THE EDITOR.

Daily Newspapers Publishing Radio News and Programs

AS a part of its service to readers RADIO WORLD publishes herewith the names of daily newspapers which carry radio programs and radio news. Wherever possible the name of the radio editor of the paper is given. Additions to the list will be published as received.

Oakland Tribune, Oakland, California. Publishes radio programs. Radio editor, Seth T. Bailey. Operates Radio Club of the Oakland Tribune, Station KLX.

The Chicago Tribune, Chicago, Ill. Lists Chicago stations somewhat fully and gives the program hour of about 20 outside stations, making mention of "specials." Elmer Douglass, radio editor.

The Sun, Baltimore, Md. Carries radio programs in morning, evening and Sunday issues. Frank Chapman, radio editor.

Illinois State Journal, Springfield, Ill. Carries daily radio department, which includes the programs of broadcasters throughout the country. S. Leigh Call, editor.

The Birmingham News, Birmingham, Ala. Publishes daily programs of its local broadcasting station, WSY. Sunday department sketches programs for the coming week of large broadcasters. Jack Turner, radio editor.

The Boston Post, Boston, Mass., publishes very complete programs and devotes from one to two pages to radio daily and Sunday. Lewis S. Whitcomb, radio news editor. Prof. Henry Bayard Phillips, technical editor.

Waiting for the Stinger

HE was running a small hardware store in a newly developed district, and the wholesale dealers found him backward in payment of his accounts. They sent him letter after letter, all of them polite, but each more threatening than the last. Finally they sent their representative down to give him a sporting chance.

"Now," said the caller, "we must have a settlement. Why haven't you sent us anything? Are things going badly?"

"No, everything's going fine. My bankers will guarantee me all right."

"Then why haven't you paid up?"

"Well, you see, those threatening letters of yours were so well gotten up that I've been copying them and sending them out to some customers of mine who won't pay up, and I've collected nearly all outstanding debts. I was only holding back because I felt sure there must be a final letter, and I wanted to get the series complete."—Forbes Magazine.

Thanks for the Appreciation!

EDITOR, RADIO WORLD: I take this opportunity to express my gratification with such a high-grade radio publication as RADIO WORLD and for the good it is doing the radio business.

Very truly yours,
THOMAS McNULTY.

7249 Rhodes Ave.,
Chicago, Ill.

Are You Coming to New York?

ARE you an out-of-town radio dealer or manager of a radio department for one of the big stores? And are you coming to New York in the near future? If so communicate with us and, we believe, it will be to your advantage. Address Business Manager, RADIO WORLD, 1493 Broadway, New York City.

Western Union's Revenue for Past Six Months

THE Western Union Telegraph Company, for the first six months of 1923, reports gross revenue, including dividends and interest received, of $56,097,327, comparing with $50,603,181 in the same period last year. Total operating expenses, including charges for repair and reserves for depreciation, aggregated $48,141,299 against $43,856,579 in 1922, leaving a balance, after all expenses, of $7,956,028 against $6,746,602. After deduction of interest charges on bonded debt there remained net income available for the capital stock of $6,802,603 against $5,593,177 in 1922.

E. Y. Gallaher, vice-president and controller, in his statement, says that the expenses for the first half of 1923 include charges for accrued proportion of employes' income participation, whereas no corresponding charges were incurred for the same period of 1922.

Mr. Kullman Is a Great Radio Enthusiast

P. C. KULLMAN & CO., New York City, "the wireless brokerage house," is sending out the fifth of a series of circulars designed to "put radio on the map of the world." This latest piece of constructive propaganda has been mailed to officials in charge of wireless telegraphy and radio telephony in 112 foreign countries. It gives interesting information of radio development in the United States, including the following statistics:

UNITED STATES

Trans-Oceanic Stations	12
Experimental Stations	292
Broadcasting Stations	591
Point-to-Point Commercial Stations	128
General Public Service Stations	41
Aeroplane Stations	2
Technical Training School Stations	128
Amateur (Licensed) Stations	18,357
Limited Public Point-to-Point Stations	40
Ship Stations (Estimated)	3,000
Amateur (Unlicensed) Stations (Estimated)	3,500,000

Mu-tron Radio Corp., install radio, $250,000; Geo. A. Blackford, Wheeling, W. Va.; A. Tegarden, Martin's Ferry, Ohio; T. M. Darrah, Wheeling, W. Va. (Horace G. Eastburn, Wilmington, Del.)

Harlem Radio, $5,000; H. C. Bernheim, M. Lovett. (Attorney, M. L. Gilman, 27 Cedar St., New York City.)

Associated Manufacturers Of Electrical Supplies Hold Annual Convention

THE annual convention of the Associated Manufacturers of Electrical Supplies was held at the Hotel Griswold in New London, Conn., recently, with a large membership in attendance.

This association is a representative of the engineers and executives of the leading electrical industries of the United States, an organization which in the versatility of its aims and objects as well as membership exceeds any of its kind in the country.

With the expansion of the radio industry, a section of the society was formed by radio manufacturers. The chief objects of the Radio Section are to further the simplification and standardization of radio apparatus, to develop among the radio manufacturers more efficient manufacturing processes, and to establish a centralized bureau for the dissemination of unbiased radio information, whether news or technical, for universal press consumption.

Up to the time of the present convention, which marks the second year of the establishment of the Radio Section, radio representatives have acquired a wealth of knowledge on all phases of their activities by virtue of the contact between radio manufacturers and electrical manufacturers. That the presentation of papers before the various meetings of the association by those engaged in electrical manufacturing, has materially enhanced the working knowledge of the radio producers, is indicated by the measures adopted by the latter at the recent convention. These measures, when carried by the radio membership, will make for simplicity in design and operation of radio equipment of every description and the standardization of complete sets and parts.

The Committee on Publicity has adopted measures which set a definite policy with respect to future shows and exhibits, these measures to be helpful to the radio memberships of the association. Recommendations were made for the establishment of a centralized office from which newspapers, radio magazines and others interested might apply for information on radio subjects.

During this convention the following officers for the Radio Section of A. M. E. S. were elected to serve during the period of June, 1923, to June, 1924: Chairman, E. B. Mallory, Westinghouse Electric & Mfg. Co.; Eastern Vice-Chairman, D. R. Murdock, William J. Murdock Co.; Western Vice-Chairman, C. E. Hammond, Signal Electric & Mfg. Co.; Secretary, Quinton Adams, Radio Corporation of America; Treasurer, George E. Eltz, Jr., Manhattan Electric Supply Co.

General Electric Handling Tremendous Business

ORDERS received by the General Electric Company for the six months ending June 30 totaled $164,263,755, compared with $114,219,248 for the corresponding period of 1922, or an increase of 44 per cent., according to a statement made public last week by President Gerard Swope. For the first quarter the orders totalled $84,249,710, as compared with $62,883,948, or an increase of 34 per cent.

Explaining Aerial Discharges on Steamer

Editor, RADIO WORLD: In reference to the query from E. M. Pace, of 807 Cherry Street, Vicksburg, Miss., in the June 23d issue of RADIO WORLD, I would like to advance the following theory which may possibly explain the electrical discharges from his aerial on the Mississippi steamer.

Though it is not possible accurately to state the cause without observing conditions as they existed, I would offer the explanation that the discharges from his aerial were due to negative charges being carried away through small particles of matter which came in contact with it. These particles might be dust, carbon (in the smoke) or water from steam. The latter would tend to explain the excessive discharges when the boat whistled, since the whistle would probably be equivalent to turning loose at boiler pressure a good-sized pipe of steam.

It is a well known fact that an insulated conductor will have a charge of approximately 60 volts for every meter that it is distant from the earth, provided the negative charge can be carried off. This may be accomplished experimentally by suspending an insulated metallic vessel in the air and allowing water to drop slowly from it.

If a condenser was used in series with the lead-in, this charge would be stored till the air gaps between plates could be broken down.

The fact that this phenomenon was not present at night may have been due to dampness in the air allowing the charge to leak off as it was formed, or the fact that the smoke or steam did not pass the aerial due to change in direction of the wind or the boat. The starting up of the boat's generator at night also may have had considerable effect on neutralizing the removal of negative charges from the aerial, as suggested by Mr. Pace. It is entirely possible that the generator may have had the negative lead grounded, either intentionally or accidentally. This ground would extend to the stack or steam piping, thus giving the small particles an initial charge, so that further charges could not be carried away from the suspended wires; or if other suspended matter were responsible for removal of charges, enough charges of opposite sign would be added to neutralize the effect. This principle has recently been demonstrated by Prof. Bancroft, of Cornell University, in his experiments for dispersing clouds by use of charged particles of sand. These unite with oppositely charged particles of water and fall as rain.

In the opinion of the writer this method of producing a charge on an insulated conductor is responsible for a goodly portion of the so-called "static" which is far less noticeable when a loop aerial is in use that is not subject to this effect. I believe it might lead to interesting results if the Bureau of Standards or other capable organization would make some tests along these lines with the object of reducing static by use of initial charges on the antenna.

This condition, I believe, could be relieved, to some extent at least, by using either the condenser shunted around the primary tuning coil instead of in series; or, better still, by using a tuning arrangement in the aerial circuit which would not require a condenser. These arrangements would leave the aerial practically grounded and thus carry off charges as they were formed, though possibly with the accompaniment of considerable "static."

Another preventative would probably be the relocation of the aerial so that no smoke or steam would pass it; though it is possible that there might be enough suspended particles in the air to still give the effect.

Hoping this discussion will help a fellow-reader of the RADIO WORLD as many others have aided me, I am,

Very truly yours,
J. FRANK NAUGLE.

The Small Boy Chooses Radio

WHEN a small boy is confronted by the problem of choosing between a radio concert and studying for examinations, the radio generally wins—that is, if mother and father are not near to influence the choice.

A ten-year-old Philadelphia youngster, writing WGY at "Skednety," N. Y.—Schenectady was a little bit too much for him—took advantage of his mother's absence and scribbled a note to WGY as follows:

"I was one of your manny radio fans of Tuesday night, June 18, 1923. I wish you to accept a thousand compelments from me. I am only a boy ten years old and a radio fan. I have built a set with a peanut tube. My mother says I pay more attenchion to it than to my studies and this leter looks it. I was lisning Tuesday night to WFI in my own city and all of a suddan I heard in a stearn loud voice 'this is station WGY, the next number is——' I blotted out WFI intirly. You had some power. Oh boy!"

"Verry cincerely Yours."

(Name withheld for reasons shown in postscript.)

"P. S.—My mother is out I guess it looks it. Please excuse this as I haf to get it out to you before she sees it. She will tare it up and say 'Get to your studies young man,' as my examanations are going on."

Evidently mother came in before the young Philadelphian could get a stamp for his letter. In the upper right hand corner, generally decorated by a postage stamp, he had written, "Collect on the other end please."

Future of Radio on the Pacific Coast

IN any business, as in radio, certain portions of the United States respond more readily, buy more freely than others. This is chiefly an economic condition. Respecting this declaration it might be truthfully stated that the Pacific Coast is the "bright spot" in the radio business to-day.

Radio manufacturers and wholesalers say there are two chief reasons for this —the climate lends itself to easy reception of broadcast matter and secondly, the excellence of the broadcast programs.

Human nature, in most cases, leans towards laziness; it is only natural that they should seek luxury. If the climate on the Pacific Coast permits facile reception and does away with tedious "tuning in" the public is certainly more interested in doing something where they can easily obtain a result. Hundreds and thousands of dollars have been spent by private enterprise in the perfection of broadcasting apparatus and the securing of artistic entertainment, with the direct result that the public is eager to "listen in," knowing full well they will hear something worth while.

It is logical to conclude that with the varied programs, large number of Class B stations, a suitable climate to enable easy operation of radio sets, a greater proportion of the western Pacific public would be inclined to experiment along radio lines.

Numerous opinions and analyses have been printed on the economic trend of radio business. In the last analysis it is merely a repetition of what has happened in many other businesses. With the country-wide interest aroused in radio, manufacturers went wild, produced sets and supplies not for the purpose of improvement or quality, but to supply the demand. In 1922 the Pacific Coast market was flooded with "junk" and it has taken six months to liquidate these goods. Prices were smashed. Competition was keen. Hundreds of inexperienced men, who had entered the radio business with no knowledge of what they were selling, went to the wall, sold out and quit. Radio then began to stabilize itself.

We all know the story. New prices —better apparatus—a continual striving for long distance reception—new inventions and a hundred and one other issues. The Pacific Coast was hit hard and took longer to recover because radio had instituted itself very strongly into the daily life of the western public.

It is a proven fact that radio is here to stay and its future on the Pacific Coast is dependent upon the prices of eastern manufactured goods and the merchandising service rendered. If the western public can get their goods when they want them and at a price to suit their pocketbooks, they will buy.

Advertising has played a great part in the development of radio business on the Pacific Coast. Month after month national radio periodicals have placed their columns before our buying public, showing every conceivable make and style of suitable apparatus and the public have bought. Sometimes they have been satisfied, sometimes not, and it still remains true that the greater part of developed business in the west has been due to systematic advertising in local and national periodicals as well as the efforts of the local representatives.

The Pacific Advertising Agency has for the past year, centered a large part of its energy in the placing of radio advertising copy. They saw in that field an opening to develop sensible advertising. It has been their endeavor to "prick the bubble" of sensationalism, do away with vague and misleading copy and advertise radio goods for their actual worth. Pacific Coast manufacturers have backed them up in their effort, realizing that the ultimate success of their business either in the West or the East, was partially dependent upon a true portrayal of their product's worth.

Maintenance of a policy of conservatism will increase the confidence and trust of a sadly misled public and make for bigger strides in the future of radio.

Perhaps the most potent factor from an advertising manufacturer's viewpoint, is the value of keeping his name before the public. Competition is too keen on the Pacific Coast to trust to the individual sale as an advertiser. The public is confused. The buying field is large. The buyer must choose. And what does he buy? Generally a well advertised product that has proven its worth and practicability, for the Pacific Coastean is well known as a skeptic. It is only the truth which will bring the radio public to a greater confidence in the radio wholesaler and retailer.

General Electric's Wonderful Increase in Sales

THE annual sales of the General Electric Company increased from about $12,000,000 to $243,000,000 in the thirty years between January 1, 1893, and January 1, 1923, according to a statement issued by the company.

The outstanding capital stock increased from $35,000,000 to $184,000,000, and the value of its manufacturing plants from $4,000,000 to $167,000,000. The number of employes grew from 4,000 to more than 74,000.

The statement was issued as a review of the corporation's accomplishments under the leadership of Charles A. Coffin, who is retiring as chairman of the board after thirty years of continuous service. Tribute is paid also to the accomplishments of E. W. Rice, Jr., former president of the corporation, and to its corps of engineers, including Professor Elihu Thomson and Dr. Charles P. Steinmetz.

Mention is made of Thomas A. Edison, who gave the world the first central plant in which to generate electricity for public lighting.

Broadcasting Forecast in "Looking Backward"

DO you remember the interest created in 1887 by the book "Looking Backward," written by Edward Bellamy? He was classed as a new Jules Verne, but many people hooted derisively at some of the prophecies in his story. If you are too young to have read Bellamy's book ask your parents or grandparents if they remember the passages quoted below. They certainly read like an inspired forecast of present-day radio broadcasting:

"Come, then, into the music room," she said; and I followed her into an apartment finished without hangings, in wood, with a floor of polished wood. I was prepared for new devices in musical instruments, but I saw nothing in the room which, by any stretch of the imagination, could be conceived as such. It was evident that my puzzled appearance was affording intense amusement to Edith.

"Please look at today's music," she said, handing me a card, "and tell me what you would prefer. It is now five o'clock, you will remember."

The card bore the date of September 2, 2000, and contained the longest program of music I had ever seen. It was as various as it was long, including a most extraordinary range of vocal and instrumental solos, duets, quartets and various orchestral combinations.

I observed that this prodigious program was an all-day one, divided into twenty-four sections, answering to the hours. There were but a few pieces of music in the 5 p. m. section, and I indicated an organ piece as my preference.

She made me sit down comfortably, and, crossing the room as far as I could see, merely touched one or two screws, and at once the room was filled with music of grand organ anthem.

"Grand!" I cried as the last great wave of sound broke and ebbed away into silence.

"Wait a moment, please," said Edith. "I want to have you listen to this waltz before you ask any questions." And as she spoke the sound of violins filled the room with the witchery of a summer night. When this had ceased she said: "There is nothing in the least mysterious about the music, as you seem to imagine. It is not fairies, or genii, but by good, honest and exceedingly clever human hands. There are a number of music rooms in the city perfectly adapted acoustically to the different sorts of music . . . connected . . . with all the houses of the city whose people care to pay the small fee. . . .

"There are on that card for today, as you will see, district programs of four of these concerts . . . which can be heard by merely pressing the button. . . .

"The programs are so co-ordinated that the pieces at any one time simultaneously proceeding in the different halls offer a choice not only between instruments and vocal, and between different sorts of instruments, but also between different motives from grave to gay, so that all tastes and moods can be suited."

Zion Broadcasting Station WCBD

STATION WCBD, owned and operated by Wilbur Glenn Voliva, is located at Zion, Ill., on Lake Michigan, midway between Chicago and Milwaukee. The station slogan is, "Where God Rules Man Prospers." J. H. Depew, manager, writes to RADIO WORLD as follows:

"We have been requested by various listeners to our station and programs to furnish your magazine with our schedule and call letters.

"I am enclosing schedule, and you will note that we broadcast on 345 meters, or under the new arrangement of 870 kilocycles frequency, and that our call letters are WCBD.

"This is a standard Western Electric equipment with 'T' type aerial, and 150-foot towers, standing at an elevation of 234 feet above Lake Michigan. At present we are using two oscillating tubes of 250 watts each and two tubes of modulation.

"This station, complete, cost about $40,000, and is said to be one of the best equipped in the country.

"A cordial invitation is extended by the management to the editor and any one associated with your valued magazine to pay us a visit at any time you are passing this way.

"Station WCBD is located in plain view of Sheridan Road in the city of Zion, and is open to receive visitors every weekday."

The schedule sent by Mr. Depew reads:

EVERY LORD'S DAY (SUNDAY)

Zion Orchestra, from 9:00 a. m. to 9:45 a. m.

Principal Service of the Entire Week, from 2:30 p. m. to 5:30 p. m.

Special Music by Zion Band, Organ (one of the largest in the world), and Zion White-Robed Choir.

Address by Wilbur Glenn Voliva, General Overseer of the Christian Catholic Apostolic Church in Zion.

EVERY MONDAY

Concert, beginning at 8:00 p. m.

EVERY WEDNESDAY AND FRIDAY

From 2:30 p. m. to 3:45 p. m.

Sacred solos and duets, and an address either by Wilbur Glenn Voliva, General Overseer of the Christian Catholic Apostolic Church in Zion, or one of his representatives.

EVERY FRIDAY

Concert, beginning at 8:00 p. m.

All broadcasting is done on local daylight saving time.

This schedule effective until October 1, 1923.

Address .....

City and State.....

If you wish two maps, one for yourself and one for a friend, send $5.00 for a yearly subscription and the two maps will be sent to different addresses if you wish.

Heard Over the Radio Counter

PART XXI.

WHEW, gosh all fishhooks, but it sure is warm! Are you too warm to give me a little information?"

"You're right, it's warm, but as for the information, if I can give it, why summer or winter does not matter."

"Well, I had my set out in camp last week, and it was working fine and dandy, until that terrible rain storm. I think it must have gotten wet, but I don't see how it could, as I had it sitting on a box; ever since, I can't seem to get it working right Probably you can give me some idea of why it doesn't function since then."

"Wow, man, you sure are a bear at asking questions, but tell me where were your batteries?"

"Oh, I had my filament battery in the cabinet, but I left the B battery down on the ground. It got soaked, but I laid it in the sun and it dried out all right. I just bought it before I left, and it looks O. K."

"There is your trouble, old man. It is a funny thing, but I had another camper in here this morning who told me the same thing, only he had his set in a car, and the batteries got soaked. I think if you get another battery you will find that your trouble was right there."

"O. K. You had better give me one right away. Say, what is that funny looking thing there?"

"Why, a new loud speaker that is very good. Would you like to hear it?"

"I don't mind if I do, I have to get one sometime, so I had better start looking around now and get some idea of what they are."

"Will you step over here? I'll show you how it works on a detector and one step."

"Why, that sounds real clear. Who is that?"

"It must be WJAQ, because they were on about ten minutes ago."

"What is the price of that?"

"That sells for $6.00, with six feet of green cord and a plug to connect it with. Say, listen to that violin! Sounds natural, doesn't it?"

"Well, if I didn't know that it was coming from that funny looking thing I would think that he was right here. Better pack that one up for me. I don't think I can go wrong, and I don't want to make the mistake I did before. I waited for tubes to come down, and they went skyrocketing up instead, so think I will take it now."

"Perfectly all right with me. Just one moment, and I will have it wrapped up for you."

"Here you are. That is the correct change, so I won't wait for a slip. Here, take a smoke on me. Well, guess I will trot along, and get it working."

"Good day, sir. Drop in anytime I can help you along."

"Thanks, I will. Good-bye."

Ideal Control For All Tubes Especially U.V. 199's

Patented

and all dry cell tubes, permits accurate and superfine adjustment necessary at critical operating point. Utilizes great tuning possibilities of vacuum tube itself.

Replaces the rheostat! Occupies little space on panel. No redrilling necessary.

200 at Dealers Everywhere

GUARANTEED

The FIL-KO-STAT is to all purposes "fool proof." Each instrument is packed with the maker's guarantee that it will be replaced if broken within one year.

triple tested

Not just fabricated and assembled. Each Fil-Ko-Stat is triple tested, carefully calibrated, then actually *operated* on a tube before shipment.

Reliability and durability backed by guarantee. **No disks to break or chip.**

FIL-KO-STAT MEANS

—stations you never heard before.
—absolute noiseless operation.
—complete control of electronic flow in the tube.
—the assurance of laboratory tests that you have the best filament control for **any make of tube.**
—filament control eighteen times greater than with a wire rheostat and many times that of any other so-called filament control.
—lengthened life for your tubes.

The filament kontrol of infinite adjustment

FIL-KO-STAT

REGULATED

The Fil-Ko-Stat is regulated at the factory to the ideal "off" point for all tubes, obviating the necessity of tampering with any screws or adjustments.

Construction of New Type Transatlantic Receiving Sets
By M. B. SLEEPER
Fully Illustrated. Price 75 Cents

IN addition to the listening to ships and broadcasting stations on short wave lengths there is a peculiar fascination about listening to the high-power telegraph stations of England, France, Germany, Russia and Italy as well as those located in the Pacific Ocean and the Oriental Countries. It is much easier to do this than most people imagine. The sending is very slow, a feature of assistance to the beginner in telegraphy. Several types of receiving sets for this task are described. Detectors, amplifiers, oscillators, etc., for long distance reception are also described. Suggestions for the operation of relays by the signals and the reproduction of them on a phonograph are given. In addition there is some valuable data on home made wavemeters for testing and experimenting.

More Reasons Why CROSLEY Better-Cost Less Radio Products are so Much Better

By perfecting the new Crosley Duostat universal filament control rheostat, the Crosley Manufacturing Company has made their instruments more efficient because of the:

1. Efficient, smooth, uniform control of all tubes duo-wound to low and high resistance 10 to 20 ohms.
2. Plunger type contact actuated by a special spring, insuring uniform pressure at all times.
3. Spring washers producing uniform tension.
4. Positive rugged stop at zero resistance or "on" position.
5. Circuit interrupted at "off" position.
6. Resistance material having zero temperature co-efficient.
7. Windings protected by a black moulded shell of high heat insulating material.
8. Electrical connections substantial in construction.
9. Design of parts to prevent warping.
10. Extremely low operating temperature with all tubes.

The outstanding performance of all Crosley Radio Sets is due to the effective co-operation of the new "Filament Control Rheostat" with the other parts.

IMPORTANT NOTICE

While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

Protection of Trade-Marks in Latin-America

THE Inter-American High Commission has issued a detailed explanation of the convention adopted at the recent Santiago Congress to harmonize American and Latin-American laws affecting trade-mark and patent protection.

There is a fundamental difference, it is explained, between the trade-mark laws of the United States and those of Latin America in that right of protection to a trade-mark is obtained in the United States through use, while in Latin America such protection is obtained through registration.

"The provision which covers this essential difference in the national practices is especially important for the American trade-mark owners," says the statement, "and it is believed that, giving them full protection, it does not violate in any way the laws of the Latin-American countries. The main principle which has inspired the convention is the principle of protecting rights legitimately acquired."

One article of the convention provides that "all differences between the contracting states relative to the interpretation or execution of this convention shall be decided by arbitration."

Tore It to Scraps

ONE of our readers writes to tell us this: Last week the local broadcast station made the following announcement: "Miss Xantippe will now render that famous ballad entitled 'Kiss Me Again.'" Believe me, fellows, she didn't rend it—she positively ripped it to shreds!

RADIO WORLD'S SPECIAL TWO-FOR-PRICE-OF-ONE SUBSCRIPTION BLANK

RADIO WORLD, 1493 Broadway, New York City.

Enclosed find $6.00, for which send me RADIO WORLD for twelve months (52 numbers) and also, without additional cost, Radio News or Popular Radio, or Wireless Age or Radio for twelve months.

Name .....

Street Address .....

City and State .....

This Offer Good Until Only August 20, 1923

Take Radio Camping With You

By Velma Carson

WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY.

IT takes one more paddle to go canoeing nowadays than it used to. Besides the one for propelling the boat, there must be a paddle for catching concerts.

And besides a girl, some cushions, a camera, and a lunch basket, the young man takes along a small radio receiving set. They come now in small boxes with a handle and are as easy to carry as any of the aforementioned prerequisites to the successful canoe trip.

He puts the set between himself and the girl in the bottom of the boat, places the extra paddle perpendicularly against the back of the seat and has her lean on it to hold it secure. Then he attaches one wire to the upright end of it for an aerial and trails the other wire in the water to ground his circuit. They put on the headphones. He tunes in to the nearest station and paddles off to the shadiest nook he can find.

Imagine this canoe on a moonlight night away off down the river and an unseen orchestra playing "Melody of Love"!

If there is any time in the world that a person is in the mood for good music it is at the end of a long, thrilling day exploring in the woods or doing any of the relaxing things that are a part of camp life.

Even the rattlety-bang piano player with a one-sided repertoire, or the banjo picker who knows eight old songs, or the sixteen-year-old with a thin voice and ukulele have always been welcome in a summer camp. Well, if the man who can improvise on a mouth organ has had his share of appreciation out in the woods, the radio, with its diverse programs, is sure to be listed right along with the iron skillet when the question comes up concerning camping paraphernalia.

The business man who wants to hide himself from business annoyances, the telephone, newspapers, and other people, can still get the news of the day and satisfy his curiosity about the baseball scores.

If mother does not care about too much strenuous hiking and swimming, she can be sure of having entertainment while she rests in camp. The children can be kept occupied at the awful hour of bedtime, and the young people can have dance music without the trouble of importing a victrola or a piano. Besides, if one is to go into wilds sufficiently wild these cumbersome instruments are practically impossible.

One group of Camp Fire Girls learned the joy of doing interpretive dancing in their bare feet on grassy slopes near their camp in the North Woods by radio last summer. They also studied the art of telling stories from the Dreamtime Lady.

It is no small help in any camp to get the weather report and river conditions.

"Humoresque" goes beautifully with bacon and eggs or trout and flapjacks, and does not detract in the least from the chirp of crickets.

Fans, Watch Your Step

NOW that no broadcaster from the United States reaches Porto Rico we wonder what will our friends do for a list of stations heard. A little imagination and a good radio call book can accomplish wonders. Be careful how you connect that ¼-kw. "coffin" to the S. P. D. T. switch. The boys at the university must have made a mistake.—*Porto Rico Radio News.*

Sleeper's Two Latest Radio Books

Two new and remarkably good radio books by M. B. Sleeper —one is entitled "Six Successful Radio Sets," with design data and instructions for receiving sets specially selected for exceptionally long distance reception. The other is "101 Receiving Circuits," being a most complete compilation of diagrams including circuits for a generative, superregenerative, Reinartz, Flivver, Flewelling, super-heterodyne, reflex and radio frequency sets. Each book mailed on receipt of fifty cents and ten cents extra for postage. Both books for $1.00 and no extra charge for postage. The Columbia Print. 1493 Broadway, New York City.

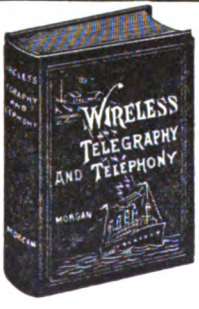
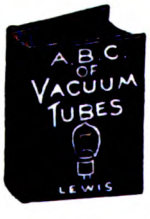
Telling How to Operate a Radio Set—How to Build a Set—Principles of Vacuum Tubes and Other Radio Problems



Wireless Telegraphy and Telephony Simply Explained

By ALFRED P. MORGAN

One of the most complete and comprehensive treatises on the subject ever published. A study of its pages will enable one to master all the details of the wireless transmission of messages. The author explains in simple language the theory and practice of wireless telegraphy and telephony. 154 pages, 156 engravings.....PRICE $1.50



The A B C of Vacuum Tubes Used in Radio Reception

By E. H. LEWIS

Assoc. I. R. E., and Radio Instructor

Written particularly for the person who "knows nothing about radio," but who would like to gain an understanding of the elementary principles of operation of vacuum tubes and various circuits in which they are used for the reception of radio-telegraph signals and radio-telephone music and speech. Illustrated.....PRICE $1.00

Experimental Wireless Stations

By P. E. EDELMAN

Tells how to make apparatus to not only hear all telephoned and telegraphed radio messages, but also how to make simple equipment that works for transmission over reasonable long distances. Then there is a host of new information included. The first and only book to give you all the recent important radio improvements, some of which have never before been published. 392 pages, 167 illustrations....PRICE $3.00

Big Opportunities for Inventors in the Radio Field

RADIO is undoubtedly the most fertile field for the development of invention that man has under cultivation at the present time, says a writer in the New York *Tribune*. Moreover there is the greatest possible incentive to invention because of the intense public interest which broadcasting has brought about.

All of the big industrial companies are fully aware of the possibilities, and they maintain extensive research laboratories in order to solve the problems which face them in the orderly evolution of the radio art.

As a result of the stupendous growth of radio as an amusement enterprise through the medium of broadcasting, the other aspects of the art have been to a certain extent overlooked, yet they are as a matter of fact vastly more important. Just think what radio communication is as a method of insuring life and property at sea, especially the radio compass in protecting valuable ships!

Take, for instance, the value of radio in cases of distress. The difficulty of equipping every vessel which floats is not so much a question of expense for apparatus, as one of expense in maintaining operators aboard so that a continuous watch may be had. Most of the tramp steamers would be quite content to have apparatus aboard which would flash the distress call in case of need.

Under these circumstances an automatic device which would continuously send out the distress call when the captain of a tramp steamer pressed a button would be a most valuable contribution to the art. Such an apparatus would adequately cover the needs of the tramp steamer because the radio compass instruments upon other ships or at land stations would enable other operators to get the necessary information the moment they heard the distress call.

The greatest drawback to the development of trans-Atlantic wireless communication at the present moment is interference. Continuous wave telegraphy has improved matters a great deal, but there is still a lot left to be desired.

Radio, while it may not immediately supplant the cable, will in the near future supersede it. The reason is that in radio there is none of the inherent difficulties which exist in cable operation. Theoretically there is no limit to the speed which trans-Atlantic wireless communication can be operated at. Automatic transmitting and receiving equipment already allows a speed of 200 words a minute under favorable conditions. This may eventually be increased to 1,000 words a minute.

If some means could be devised whereby dots and dashes could be dispensed with altogether and an electrical recording instrument operated by variations of frequency in alternating current above the range of human hearing the problem of interference would be quickly eliminated.

Audible frequencies, roughly speaking, range from 200 to 5,000 alternations a second. Above the latter figure there is a tremendous range which could be taken advantage of in the formation of a code of signaling, provided apparatus could be perfected which would follow the rapid change in frequency and record those changes.

In this manner continuous application of modulating current would be obtained and the present system of breaking up the current to form the dots and dashes would be avoided. Such a method would also take away the present interference caused by the low wave telegraph stations upon broadcast reception. It would, in fact, leave all of the audible band of frequencies for the exclusive use of radio telephony.

It is hardly necessary to point out the need for a static eliminator. The inventor of such a device would be in a position to write his check for any amount of money his fancy might dictate. It would at once remove the curse from all wireless telegraph communication and permit the instantaneous linking up of every part of the world in the most economical manner.

For broadcast listeners it would be an inestimable boon, and from this source alone a very large fortune could be obtained by the successful inventor. In the realm of radio telephony it would enable us to establish immediately day and night telephone communication with all parts of Europe in such manner that the radio system could be effectively and economically linked up with the land telephone systems on both continents.

Do You Want LONG DISTANCE on Your Set?

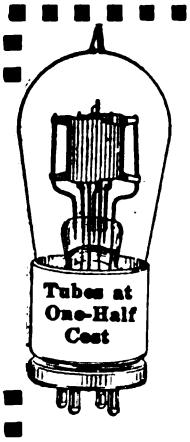
French Airplane Steered by Wireless 250 Miles

A PARIS dispatch to the Associated Press states that a French government airplane has successfully completed a flight from the Saint Assisses wireless station to Tours and return, a total of about 250 miles, steering only by wireless.

The indications were received on an apparatus called the radio goniometer, which showed the airplane's position with relation to the wireless station. This device enabled the pilot to make the journey with an error of only 2 per cent in direction on the outward flight and with entire accuracy on the return.

The test was announced as proving the practicability of such a method for night flying.



IT HAS HAPPENED TO ALL OF YOU IN A FRACTION OF A SECOND!

WHEN the filament burns out, at least $5.00 goes with it to put the set in operation again.

WHY not save nearly one-half the cost of a new tube by sending us your burned out or broken tube to be repaired?

WE REPAIR EVERY TYPE OF tungsten wire filament receiving tube. All our tubes are TESTED and GUARANTEED to function as well as when new.

All tubes returned P. P., C. O. D.

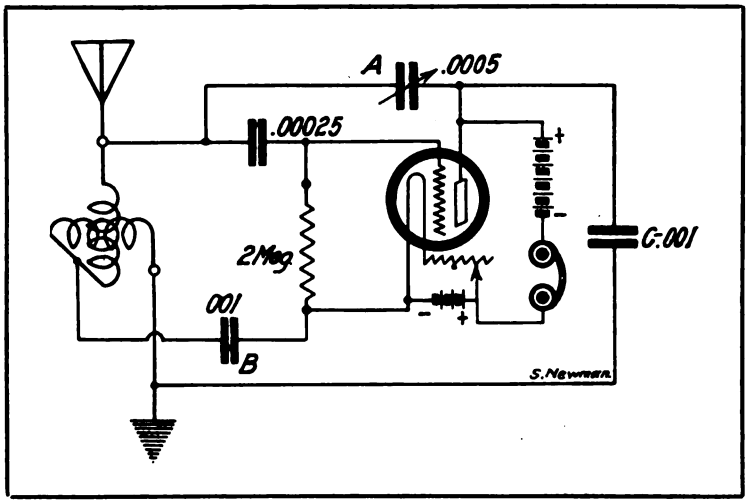
A Dry-Cell Tube Circuit That Will Surprise You

By A. D. Turnbull

THERE has been much said lately about the relative capabilities of single circuit sets versus tuned circuit and the interference caused by re-radiation in the case of the first mentioned type. Discounting the fact that a single circuit set in the hands of an amateur is capable of creating a private bedlam all its own, there is probably no type of circuit yet discovered that will give the volume on one tube that this type will deliver. Furthermore, when you combine capacity feedback and the super-regenerator principle, a circuit of this type will produce signals that are equal to a triple circuit with at least one stage of audio and radio-frequency amplification.

A circuit that is easily controlled and that will, if operated properly, produce exceptional results in both distance and volume, is shown on this page. As can be seen it combines several features not found in any other circuit. It is flexibility personified, as with an ordinary type of variometer and an antenna of from 75 to 100 feet in length it will tune from 180 to 600 meters with no trouble at all. It is as efficient on 200 meters as it is on 600, not losing any volume or selectivity at either extreme.



Circuit diagram of a receiver that will enable the average fan to reach out and corral the long distance. Watch the condenser capacities.

Apparatus necessary for the construction of this set is easily obtainable as there are no parts that have to be specially constructed or sought for. They are: 1 variometer; 2 .001 fixed condensers; 1 .00025 grid condenser (no leak); 1 grid leak, 2 megohm (preferably tubular type); 1 .0005 vernier variable condenser; 1 dry cell tube; 1 socket; 1 vernier rheostat.

When constructing the set pay particular attention to keeping the leads separated and well insulated. If leads are allowed to run parallel the whose purpose and scheme of the receiver will be defeated as due to the capacity feedback and coupling, any extra capacity which is allowed to enter the circuit will entirely destroy the principle of the set and you will have a set which tunes broad and has no volume.

Too much stress cannot be laid on careful construction, especially the location of the condensers A, B, C. These are the controlling features of this circuit and they should be located in such a manner that the leads from one cannot interfere with the leads of another.

When the set is constructed it is necessary to shield the panel, but it should not be grounded to the ground terminal. In this set it is much better to ground it to the minus side of the filament, as if grounded to the ground terminal, it will form one side of a condenser with your body through the phones as the other and every time you go to tune the set it will break out in the most awful howls and capacity effect will be so bad that you will have to tune it with a broomstick.

The set is tuned in the following manner: The feedback capacity A is set at about 50° and the variometer is turned till the carrier wave of a station is heard. The rheostat of the tube is then turned down until it is just above the point where it "clicks" out. If when tuning this part of the circuit it goes out, go back and re-tune the filament until it is just at that point. Then using the variable condenser, tune the set until the signals are clear and loud, clearing up all the noise with the vernier of the condenser.

As advantage of the super principle is taken, a lot of noise will ensue if the circuit is not tuned correctly. So if when the set is first tuned you get lots of funny sounds do not be discouraged but learn to tune it properly and you will find that it is a very selective and sensitive circuit.

Of great importance is the tapping of the variometer. The two winding of the stator and rotor are generally connected in a manner that makes this easy as most variometers use the shaft of the rotor to make the connection, but if yours doesn't, trace the windings and tap it with flexible wire.

If trouble in clearing up the signals is noticed you

Influence of Radio on Arctic Expeditions

By Hendrick Hansen

SWINGING off to the top of the world!

A little packet of letters from members of the expedition to their friends at home, left at a tiny village at the northern coast of Labrador, and every Arctic exploration party turned toward the vast ice fields to the North with all ties to civilization broken. While their last farewells were carried back to the States, they proceeded slowly to the land of ice, darkness and Northern Lights. The world bid them "bon voyage" and forgot them for months and even years.

This briefly was the story of the departure of every Arctic exploring party of former years and the vast curtain drawn between them and home was sometimes never lifted; the hardships they were forced to undergo and the manner of their passing are mysteries never to be unfolded. As soon as their ship's anchor was hoisted at the white man's most northern outpost the trend of world events was to them closed.

How different it is now and what a contrast may be drawn between the famous Greely expedition and that in command of Captain Donald B. MacMillan who is now on his way to Ellsmere Land in the 89 foot auxiliary schooner "Bowdoin." Four strands of wire between the masts of this little vessel comprise the link that makes the parting easier and the future less doubtful.

Cheerfully will they leave their letters on the Labrador coast for they know that these are not the last farewells; radio will keep them in contact with the world below—there will be no good-bye—and while they wave a greeting to natives on shore, Donald H. Mix, their radio operator sent by the American Radio Relay League, may even then be communicating with amateurs 2,000 miles away, or listening to concerts from Chicago.

In the forecastle of the little vessel with headphones fastened over their ears members of MacMillan's crew, through this marvelous new adaptation of radio, will not only listen to the same concerts that thousands hear nightly at home, but what is of more value to them the latest news of world happenings from the Arlington station. And just as they will keep informed of national and international events as well as the result of a world championship bout or the outcome of the next presidential election, so will they describe their own vivid experience in scientific exploration.

The use of radio for Arctic work is new and untried and the results of the plan of communication, designed jointly by Captain MacMillan and officers of the American Radio Relay League, are expected to pave the way for future expeditions under vastly improved circumstances both as to the morale of the explorers and the enlightenment of science.

Should some sudden emergency overtake the exploring party and their rescue be brought about then the weeks spent in preparation, the painstaking care while the radio equipment was assembled and installed to the satisfaction of expert engineers, will not have been in vain and radio will have proved its value in a new field.

One of the spectators of MacMillan's departure from the Maine coast was Major General A. W. Greely, leader of the Greely expedition of 1881. "The whole cause for the death of 18 members of the party," he said referring to his own experience, "was due entirely to the fact that the relief expeditions failed to reach us and our supplies consequently gave out. Of the 25 members, seven were finally rescued, but one man who had lost his hands and feet died from the effects of experience in Greenland where the party stopped on its way home."

Under such circumstances what would radio have meant to the Greely exploration party? What may it mean to Donald MacMillan who is now on his way to the desolate ice fields where so many have gone but for one reason or another failed to return?

What power there is in four little strands of wire!

Ode to Electricity

By Will Chamberlain

SOME call you Jove, but back of you, I know,
There is a vaster Power that guides your flow,
That thrusts your zigzag saber through the sky,
Whose awful glitter quells and blinds my eye,
Whose magic lance rends to its heart the oak,
And smites the steeple with a sudden stroke;
Lights as with sunshine the on-rolling storm,
Causing the world to shrink from seeming harm;
Splitting the stubborn granite to the core,
Ere the slow thunder breaks with sullen roar—
And I bow down in reverence to the sod
Before a might that's god-like but not God.

Yet, scouting fear, I list you, marvelous friend,
Who at a finger's touch will noontide send;
Who, with your faithful, tiny suns, will light
The haunting blackness of the starless night;
Who at a button's pressure bids the cranks
And belts and wheels of workshops play their pranks
Of usefulness in Labor's priceless cause—
You, the invisible fashioner of laws.

And as the daring Franklin, from the shroud
Of thunderbolts that lesser souls had cowed,
Coaxed with his kite the tingling proof that we
Acknowledge everywhere on land and sea,
So I, the least of men, with frail lines plod
Before a force which says, "There is a God!"

(*Concluded from preceding page*)

can experiment with a smaller grid leak capacity, but for most dry cell tubes I have found that two megohms is about the correct capacity.

If the set is carefully constructed and directions are all closely followed, the builder will have a set that he can rely upon to bring in the most distant stations clear and undistorted and with a minimum of tuning.

Do You Watch Them?

MOST fans using dry cells for lighting their tubes never think of their batteries until they actually go dead on them. It is always a good plan to test them with an ammeter every so often. By doing this you can keep an accurate check on your filament supply and never need miss anything for need of "juice." Remember the old saying that runs something like this: "For want of a nail the shoe was lost, etc."

Helpful Summer Hints for Listeners

THESE are ten good rules for broadcast listeners:

1. Don't try to hear Australia in midsummer. Be satisfied to enjoy the nearer stations most of the time.

2. Don't be disappointed if an occasional storm interferes with your summer radio evening. There are many fine concerts coming. You can't expect to find a pearl in every oyster, nor to receive a record-breaking concert every night.

3. If you want louder signals use a longer aerial, more tubes, higher plate voltage, more sensitive loud-speakers, and more careful tickler and receiver adjustment.

4. A pleasant signal filling a moderate sized room should be enough to give satisfaction. It is not worth while producing signals which deafen the neighbors. It is wasteful to insist on tremendous signals, which are generally less pleasant than moderate signals.

5. If your local station comes in too loudly and drowns others out, a smaller aerial will help in tuning him out, with a smaller condenser connected between aerial and ground. And if all measures to get rid of the local station fail, why not enjoy his concerts? He is working hard for you, and it is nobody's fault that you are so close to him that you are bound to hear him. Broadcast stations have to be closer to some people than to others.

6. For the new longer waves above 450 meters use a condenser connected between the aerial and ground terminals of your set.

7. A little patience in learning to handle your receiver yields rich returns in satisfaction from fine signals. Remember that "Rome wasn't built in a day" and keep on getting more and more familiar with your set and how it works.

8. It is a fine idea to read a good radio magazine or two. It helps you to know how your set works and keeps you up to date in radio. Information of this sort is an aid in getting the concerts loud and clear.

9. Ask your radio dealer for advice; he can probably tell you what you want to know, and will be glad to do so. The manufacturer of your set is also willing to help you get the desired results from its use.

10. Do not throw away the direction sheets or booklet that came with your set and with the tubes. Read all such material carefully now and then. If you have lost the direction sheet write to the dealer or manufacturer for another. The direction sheet must answer most of the questions which have been puzzling you and preventing you from getting the best out of your set.

Round Trip in Three Minutes

The picture below is a view in the New York sending station of the Radio Corporation of America. Messages are sent from here direct to London, Paris and Berlin through the control station at Rocky Point, Long Island. A high-speed duplex system is used on wave lengths from 10,000 to 20,000 meters. At the right is illustrated the receiving apparatus which catches the signals automatically relayed from Riverhead, Long Island, and transmits them to operators who decode them. A round trip from New York to London in three minutes is common.

(C. Kadel & Herbert)

Tipping You Off

WHERE a set is used that combines radio-frequency and tube detector, with either straight or regenerative qualities, it is much better to use separate A and B batteries than to combine the leads so as to get all the tubes feeding from one set of batteries. You will find you will not be bothered with broad tuning and the distance you will get will be increased.

Naval Radio Development Centered at Bellevue, D. C.

By Carl H. Butman

WHAT is believed by experts of the Bureau of Engineering of the Navy to be a forward step in co-ordinating its research work, including radio development, at a single station was accomplished recently with the formal dedication of the Naval Research Laboratory at Bellevue, D. C., a short distance from the Capital.

Here are consolidated the Radio Research Laboratory formerly at the Bureau of Standards; the Aircraft Radio Laboratory, previously at the Anacostia Naval Air Station, old NOF; and the Sound Research Section of the engineering experiment station which was located at Annapolis. A group of buildings, just completed, on the shore of the Potomac south of Anacostia, comprise a power house, pattern, foundry and machine shops and the three-story laboratory building.

Radio Officers of the S. S. "Leviathan"

(C. Kadel & Herbert)

First photograph showing complete radio staff of the S. S. "Leviathan." Left to right are seen E. N. Pickerill, chief radio officer; A. C. Tamburino, first assistant radio officer; R. J. Green, second assistant radio officer; H. F. Bollendonk, third assistant radio officer; E. E. Engelder, fourth assistant radio officer; C. R. Underhill, fifth assistant radio officer.

The whole project is under the direction of Capt. E. L. Bennett, U. S. N., aide to Secretary Denby, in Washington, and at Bellevue is under the supervision of Cmdr. E. G. Oberlin, U. S. N. Dr. A. H. Taylor, formerly in charge of radio at Anacostia, is in direct charge of radio experiments, assisted by twenty technical and scientific aides and engineers All the work is of a more or less confidential nature and, it is understood, each of the employees took an oath of secrecy.

The entire third floor of the laboratory is devoted to radio and sound development. It is divided into 18 rooms averaging 17 by 25 feet. Radio work there includes the development of ideal transmitting and receiving apparatus suitable for different naval circuits, both afloat and ashore. Special work in the improvement of vacuum tubes, static elimination, amplifiers, high-speed sending and receiving apparatus, such as the teletype and printing telegraph, is being undertaken.

Problems to be studied will be limited to research in so far as they may be connected with applied science; in other words, this laboratory will not undertake purely scientific research as does the Bureau of Standards. Special problems relating to marine and military radio are studied and model sets constructed for manufacture by commercial firms. The new transmitting set for Arlington which is free from "mush and harmonics" was produced by naval radio experts at the old laboratory at Anacostia. Different styles of receivers and wave meters are also experimented with.

The work specifically covers the practical application of theoretical designs developed by Navy engineers and inventors. Modification of impractical designs is frequently necessary in the actual construction, it being the main object to equip naval vessels with the last word in radio. Sea-going specifications are far more severe than in ordinary land work, especially in radio equipment.

Bellevue has a receiving station but no transmitter, on account of possible interference. When messages must be sent out, however, a land line controls a radio transmitter at Anacostia. Every ship of the fleet does some testing in transmission on its own hook, but when necessary ships can be sent to the dock at Bellevue.

Much of the work has to do with the development of special radio apparatus for aircraft including the adaptation of the radio compass, the use of the teletype and other auxiliary apparatus. Although some tubes and batteries are tested at Bellevue, most of the preliminary work is done by the manufacturers themselves, the perfected tubes and batteries being submitted for final trial. Usually in the event a special set is desired, the engineers and laboratories construct it around the best tube available in the commercial market.

Broadcasting Station for Milton, N. Y.

RECOGNIZING the value of radio as a means of disseminating valuable information to the general public, A. Stone, the novelist, lecturer and philanthropist of Milton-on-the-Hudson, New York, and founder of the A. Stone Foundation, an organization that will devote itself toward the realization of worthy objects, is making preparations to establish a powerful radio broadcasting station upon his estate at Milton this fall. The station, which will probably be 15 kilowats, will be used for broadcasting lectures on important topics which will include science and literature. For this purpose Mr. Stone will enlist the services of nationally known lecturers while he himself will devote two hours each week to broadcasting talks on current literary topics.

Mr. Stone's place on the Hudson is an ideal location for the establishing of a broadcasting plant. Overlooking the river, the highest point is 700 feet above sea level.

Members of the Authors' League of America, of which Mr. Stone is a member, are watching the results of the experiment with a great deal of interest.

Transoceanic Radio Telegraphy

By E. F. W. Alexanderson

Chief Engineer, Radio Corporation of America

THE radio engineer is, more than any other, compelled to work with conditions which are not within his control, and only partially understood. The law of probability and averages must therefore figure largely in his calculations.

A good many of those present here are undoubtedly radio amateurs. When you have received some clear signals from Kansas or Cuba this is an interesting fact and you relate it to your friends. Many of you are, no doubt, fond of fishing especially when you have caught a big trout. That is an event worth mentioning. These are single facts highly subject to the law of chance. Nevertheless the professional fishermen succeed in providing fish for our dinner tables with great regularity. It is the aim of the radio engineer to chart the sea of the ether, to weather its storms and to provide a continuous service of communication day and night.

The transoceanic radio station is a power station. Its input is kilowatts and its output is words. The problem of radio engineering is to establish the relation between kilowatts input and words output. This relation between kilowatts and words is a chain comprising four separate subjects which are being studied by specialists in those subjects. They are:

1. Relation between kilowatts consumed and wave energy radiated.
2. Relation between wave energy at the transmitting station and wave energy at the receiving station.
3. Relation between wave energy at the receiving station and the speed at which words can be received.
4. Influence of atmospheric disturbances.

The first subject deals with the radio power station and the antenna. The Radio Central antenna is designed from the ground up. It has six ground connections distributed over a distance of one mile and 150 miles of wire buried in the ground. Through these devices the ground resistance has been reduced to 1/10 ohm. The best antenna of types previously used have ground resistances of about two ohms. The losses in the ground have thus been reduced at the rate of 20 to 1.

The second subject is wave propagation. We have now a great deal of practical data which can be summed up in the rule that the most economical wave length for communication over a certain distance is about one five-hundredths of the distance.

The third subject deals with the design of the receiving station. It has been found that the speed in words per minute at which it is possible to receive telegraph code is directly proportional to the amplitude of the wave. A signal field strength of 50 microvolts per meter corresponds under average conditions to a speed of 50 words per minute.

The fourth subject deals with the atmospheric disturbances. Our modern receiving system eliminates about nine-tenths of the disturbance but the residual which is not eliminated determines the speed of reception by the law of inverse proportionality.

For elimination of disturbances we use a new type of antenna about ten miles long. It is a simple telegraph wire mounted on ordinary poles. It is not tuned for any particular frequency, and waves of all lengths travel along the wire with the velocity of light. The ether wave thus starts a wave on one end of the wire, and this wave travels along the wire while the original ether wave follows beside it in space, constantly adding energy to the wave on the wire, just as the wind starts a ripple at one shore of a lake and rolls it up to a large wave as it travels along. Thus the wave intensity in the wire grows and becomes a maximum at the far end of the wire. Fortunately on the Atlantic coast most of the disturbances come from the west, whereas the signals come from the east. The wave antenna thus separates the signal from the disturbance so that the signal appears at the east end of the wire and the disturbance at the west end. The energy of the disturbance is destroyed by absorption in a resistance at the west end of the wire, whereas a practically pure signal can be collected at the east end.

With the data that is thus available the planning of a new radio system is no longer a matter of guesswork. Before designing our South American system we sent an expedition of engineers to chart the atmospheric disturbances. Their findings led to a modification of the original plan because it was discovered that at the location first selected the principal disturbances came from the same direction as the signal, and therefore could not be eliminated. From the data now available it is possible to calculate the number of words that can be received during each month in the year, although the stations have not yet been built.

We can thus say that radio engineering has reached a point where sound foundations technically and financially can be laid for the expansion of this system of communication.

Abstract of a paper delivered before the American Institute of Electrical Engineers.

Latin-American Officers Learning Radio

(C. Underwood & Underwood)

This picture shows Lieutenant Salcedo, of the Peruvian Army (standing), and Captain Masvidal, of the Cuban Army, learning army radio operation at the R. O. T. C. Signal School, Camp Alfred Vail, N. J.

Securing the Co-operation of the Amateur

By Kenneth M. Swezey

IN most every town and hamlet where there are at least a few amateurs, you are certain to find a radio club. Radio, more than any other popular avocation, seems to harbor such a powerful fraternal spirit that the average person has a hard time to dodge. That is, referring to the real dyed-in-the-wool amateur—the "ham." These clubs serve the purpose of bringing the members together for good fellowship, and more than that, they serve to disseminate a greater understanding of radio by the exchange of ideas, the conducting of classes and the making of group experiments. Many clubs have a very complete equipment of apparatus, both sending and receiving, along with facilities for theory instruction and code practice. And probably a goodly number of the members are experts, having at their command a proficiency above the average commercial man. Indeed, many of the members of clubs with whom the writer is acquainted hold first-grade commercial operators' licenses.

Ever since the inception of broadcasting on its present scale there has been a misunderstanding between the broadcast fans and the amateur. One continually flays the other without rhyme or reason—and simply because the existing conditions are not clearly understood. It seems that the broadcast fans have been doing most of the kicking, so I will take up the brief of the amateur, and try to show the fans the utter lack of antagonism on the amateur's part toward them.

The amateurs are not a bunch of kids whose only ambition is to disturb the ether, bust up the programs and all such nonsense. As was mentioned before, they are most of them well-trained mature fellows who are in the game for pleasure and development. During the past year they have voluntarily sacrificed a good portion of their rights for the sake of broadcasting. They resigned themselves to the very late hours of the night so that the concerts could go on undisturbed, when really they were not the disturbing factors at all, but the poor tuning ability of a large percentage of the receiving sets. The amateur wave length band is sufficiently distant from the broadcast band to enable all good sets to tune them out completely. So, after all, the amateur is not such a bad fellow.

To convince himself that what I have said is true, the best thing the broadcast fan could do is to visit one of the clubs and perhaps join it. Lists and announcements of their doings can be found in this or most any other radio magazine. You will have an interesting time and you will find the "hams" very willing to co-operate in anything pertaining to their hobby. If you have anything the matter with your set, take it along with you, and let them have a hand at trying to diagnose its ailment; it's great sport to them, and each will try to show his superior knowledge. The harder and more knotty the problem, the better it is.

It is very probable that the vast broadcasting audience would advance a long stride if they would take advantage of the service that the amateurs offer them. The ignorance that now exists would soon fade away in the light of proper instruction. There would be less worthless apparatus sold and fewer good sets ruined by lack of operating knowledge. And the amateur would be able to take a step forward because of the increased membership in the ranks and the increased capital resulting therefrom.

Just what has the club to offer the fan? Well, I will use for an example a representative club in which I have a membership. First of all, it offers to increase your friendship circle by about twenty good old scouts; that's a point not to be overlooked. And they are truly real good fellows—except that they will talk you deaf, dumb and blind about radio and nothing else. Next, it offers a person sound theory instruction on the subject. By the aid of good instructors, blackboard talks and practical demonstrations they can pump enough "dope" into your head in an evening to swell it beyond the hatband limits. Besides the regular theory, the members bring their individual problems, new hook-ups, and such things, to be discussed.

If you want code instruction, here is where you can get it, and first class stuff at that. This particular club had code tables arranged for different speeds, and had the option of either hand sending or sending with an omnigraph. I know of at least eight fellows, who joined the club with a very slight knowledge of radio, and in a few months had successfully taken their first grade amateur license examination.

The club also offers social features that are worth while. Every month or so they set aside for a festive occasion, when they have a great time with the games and their "eats." When it comes to filling the stomach, the non-technical fan can put up as good a showing as his fraternal brother, the ham.

Everything considered, the getting together of the hams and the fans would be mighty beneficial. For one thing it would instill a respect in the mind of the fan for the amateur; and the amateur might think a whole lot more of his fan brother if he knew him just a little better—just enough to realize him as human. A lot of receiving set owners would get to understand their apparatus better, and there would be less cheated and disappointed souls. And as a result of this, a great strain would be taken off the newspaper and mazagine question and answer departments. Thus more time would be given the editors to produce better goods. And the fan and the amateur will exclaim in unison, "This is Heaven! Where do we go from here?"

Where to Look for Trouble

IF you hear a constant clicking noise, like the dropping of water on a hot stove, vary your grid leak and watch your grid condenser.

If there is a steady sound like a motor running, look around for a loose or broken connection.

If your tube vibrates when the set is operated mount the socket on felt or soft rubber.

If there is a crackling sound when the coupling is increased, decrease your filament current.

If the signals stop and go and the set is functioning properly, inspect your antenna. It is probably swinging and grounding periodically.

If your set howls when you are tuning, or the signals fade when you take your hand from the controls, shield your panel and ground the shielding.

If your set will not oscillate, reverse the plate and phone leads of your tickler.

If signals are weak, look for dirt and dust inside.

A Radio-Frequency Push-Pull Amplifier Using a Crystal Detector

By J. E. Anderson, M. A.

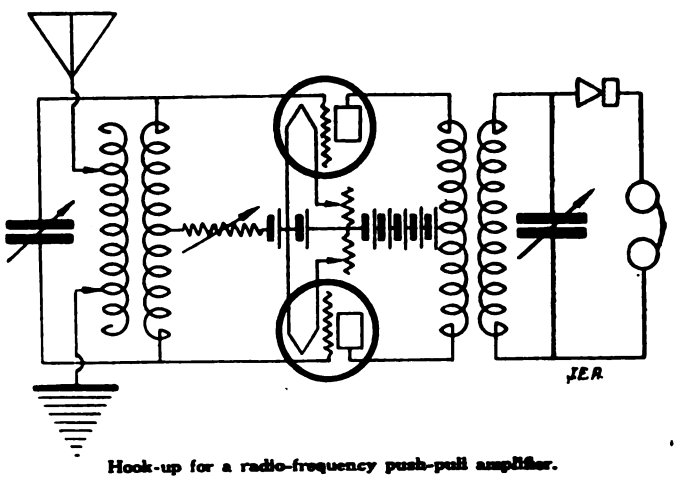
THE push-pull circuit for the amplification of audio-frequency currents is well known in radio circles, but it has not gained the popularity that it deserves on account of the difficulty of obtaining the necessary transformers. Only a few manufacturers have placed these coils on the market and the number of dealers handling them is very limited. It is to be hoped that this condition will soon be remedied, and that the coils may be procured at a price that is commensurate with the pocketbook of the average amateur, so that all who desire may avail themselves of the advantages of this circuit. In the meantime, however, we may apply the same principle to a radio-frequency push-pull amplifier and thus retain some of the advantages of the balanced circuit. This may be done at an expense no greater than that of an ordinary radio-frequency amplifier since the necessary coils may be constructed at home.

The accompanying diagram illustrates one method of connecting a push-pull radio-frequency amplifier, using a crystal detector to render the signals audible. In this circuit double tuning is used on the input side of the tubes and the output circuits are tuned indirectly through tuning of the secondary of the output oscillation transformer. The middle point of the grid coil is connected to the negative end of filaments through the common "C" battery and a variable resistance. The positive side of the common "B" battery is connected to the middle point of the plate coil and the negative side of the "B" battery is connected to the positive side of the "A" battery.

This circuit may be used without any connection between the middle point of the grid coil and the negative end of the filaments with fair results, but the grids will then be "floating" and there will be no definite grid potential with respect to the filament. If the proper negative biasing battery is inserted between these points the circuit is liable to oscillate vigorously and no signals will be heard. But the oscillations may be stopped by inserting a resistance in series with the battery as is shown in the diagram. The amount of this resistance necessary depends on so many conditions that it cannot be stated; it must be found experimentally for each circuit, and for this reason the resistance should be variable. Sometimes the circuit will not oscillate when the resistance is zero and at other times several thousand ohms will be required to stop oscillations. The tendency of the circuit to oscillate depends on the various characteristics of the tubes, the inductance of the grid and plate coils, the degree of coupling in the two oscillation transformers, and on the degree of unbalance of the two tubes.

The most important consideration in this circuit is to obtain as nearly perfect electrical balance as possible. The two tubes should be alike in all their characteristics and they should be carefully adjusted to operate over the corresponding parts of their characteristic curves. This may be done by adjusting the "C" and "B" potentials separately, but it is more convenient to use common batteries and adjust any small unbalance in the circuit by adjusting the temperatures of the filaments. The use of small compensating batteries would merely introduce complications. The adjustment for electrical symmetry may be facilitated by maintaining physical symmetry in constructing the circuit. This would automatically balance out any stray electro-magnetic or electrostatic effects. If the input impedances of the two tubes are different, the effective input potentials will not be the same, even if the electromotive forces induced in the two halves of the grid coil are the same, and the resulting currents in the two plate circuits will not be equal. This may be corrected by connecting the common grid return lead to a point to one side of the middle. This, however, is not recommended. Similarly, if the output impedances of two tubes are different, the output currents will be different, even if the effective input potentials are the same.

The best way of testing the circuit for unbalance is to insert a small coil in series with the "B" battery and to couple a detector circuit to this coil. If the circuit



Hook-up for a radio-frequency push-pull amplifier.

is perfectly balanced there will be no sound in the telephone in this detector circuit. This condition cannot be attained ordinarily in a practical circuit, but it may be approached closely by adjusting the circuit until the sound is a minimum. It will not do to insert a telephone directly in series with the "B" battery in order to test for unbalance. This would merely show whether one tube is a better detector or rectifier than the other, and would not show their balance as amplifiers.

The variable resistance in the grid circuit may be used to control regeneration as well as the oscillations, provided it is capable of variation in small steps or of continuous variation. If it is desired to use a tickler to obtain regeneration for long wave lengths, this should be inserted in series with the secondary of the output oscillation transformer and placed in inductive relation with the grid coil.

Since only one-half of the grid coil is in each grid circuit, this coil should be larger than is usual in order to get a high potential on each grid. If an 11-plate variable condenser is available the coil should have an inductance of about 400 microhenries. If a 23-plate condenser is used the inductance should be about 200 microhenries. The first combination is preferred.

Auxiliary Radio Equipment Saves Passengers

AN example of the value of auxiliary radio power in the form of batteries on seagoing vassels and the necessity of their frequent inspection, is found in the report on the total loss of the S. S. "Advance."

When the "Advance" went aground off Halifax recently, the operator found that his power was cut off soon after grounding, as it was feared there might be a boiler explosion. This made it necessary for him to shift to his emergency batteries for transmitting SOS calls to ships and shore stations. His batteries stood up one-and-a-half hours, when it became necessary to abandon ship. All lives were saved, though the vessel itself was lost, due to the bringing of aid by radio.

There would undoubtedly have been a loss of life if the batteries had not been in good shape, and it is understood that just before the vessel cleared from Boston for Halifax, a government radio inspector discovered that the old batteries were in very bad shape and condemned them. The owners immediately installed an entirely new unit of battery power supply, which insured radio communication when the regular power failed.

The Radio Woman

WHY don't more of you ladies sit down once in a while and write me your experiences or troubles or joys of the redoubtable radio set? It's really an easy thing to do, sisters, and you'd be surprised how delighted some of my readers are at seeing their literary efforts in print. The next time you have a spare minute or two think of me and tell me something about that set you are all enjoying so much. Just write as you talk—our editors will polish up your efforts.

* * *

The other night, when they were giving out the returns of the Leonard-Tendler fight, I unfortunately had an appointment and could not remain at home with my men folks who were waiting for the returns. I passed about four radio shops and at each one the same condition existed—a mob of men and women, mostly men, of course, were gathered about the store and way out into the gutter intently listening to the reports of the rounds. I was just thinking how much more comfortable my little brood was at home with iced tea to sip, cozy lounging chairs, and no crowding. If some of these men could see the picture in my mind, they would undoubtedly walk into one of those stores instead of remaining outside, and purchase the best set they could afford.

* * *

I told F. H. of the conditions existing on the outside and he said, "Well, my dear, we can't all be prosperous and some have to be on the outside or the inside will be crowded, too."

* * *

One of my little boy friends, a high school senior, is working during his summer vacation for the first time. He could have gone to the country with his mother and younger brother this year as usual but preferred to remain in the city with his dad this year. He is earning twelve dollars a week at a place quite near his home, which means no outlay for carfares or lunches and allows him to keep his salary. His intention is to work for seven weeks, save up $84.00 or thereabouts, and buy a beautiful radio set when the winter is here. His parents wisely refused to lay out the money—hence his sudden burst of worthy ambition.

New Broadcasters Licensed

EIGHT new broadcasting stations of the A Class and one in Class B were licensed during the past week by the Department of Commerce. Four stations in Class C were transferred to Class A and one to Class B.

New Class A

Call	Station	Frequency Kcys.	Wave Length, Meters	Power, Watts
KFIY	Brott Laboratories, Seattle, Wash..	1,270	236	15
WSAU	Camp Marienfield, Chesham, N. H.	1,310	229	10
WSAW	Curtice & McElwee, Canandaigua, N. Y.	1,090	275	100
KFIZ	Daily Commonwealth, Fond du Lac, Wis.	1,100	273	100
KFJI	Liberty Theatre, Astoria, Ore.....	1,190	252	10
KFJF	National Radio Mfg. Co., Oklahoma City, Okla.....	1,190	252	20
KFJC	Post-Intelligencer, Seattle, Wash..	1,290	233	100
KFJH	The Sugar Bowl, Selma, Cal.....	1,100	273	10

New Class B

WRC	Radio Corporation of America, Washington, D. C.....	640	469	500

Transferred from Class C to Class A

WWL	Loyola University, New Orleans, La.	1,070	280	100
KFCZ	Omaha Central High School, Omaha, Neb.	1,160	258	100
WLAN	Putnam Hardware Co., Houlton, Me.	1,060	283	250
WRAD	Taylor Radio Shop, Marion, Kan..	1,210	248	10

Transferred from Class C to Class B

KDZE	Rhodes Co., The, Seattle, Wash...	660	455	500

(*Concluded from preceding page*)

From 60 to 70 turns on a 3.5" tube will give an inductance of about 400 microhenries. The plate coil may be somewhat smaller than this. The magnitude of the secondary in the output oscillation transformer is not important. A 43-plate condenser with a coil of 100 microhenries may be used, or a 23-plate condenser with a coil of 200 microhenries. The antenna coil should be capable of variation in steps of a single turn.

This circuit may also be used as a single circuit tuner by connecting the grid leads directly across the antenna coil and the common grid return lead to the middle point. When this is done an antenna condenser must be used to tune the circuit. If any changes are made in the antenna inductance they must be made symmetrically with the common middle point. Another variation in this circuit may be made by eliminating the secondary of the output oscillation transformer and connecting the tuning condenser and the crystal-telephone branch directly across the plate inductance coil. This would simplify the circuit but it would render it less selective.

The circuit described here operates as a radio-frequency amplifier, and therefore only hard tubes should be used. These are not so critical and not so difficult to balance as the detector tubes.

RADIOGRAMS

WORLD NEWS HAPPENINGS BRIEFLY PHRASED FOR OUR BUSY READERS

BXZ has been assigned as a general signal call to all British war vessels.

* * *

The coast station at Puno, Guyas, Ecuador, is now open to PG service.

* * *

Amateur radio again proved its value when long distance messages were handled during the recent telephone strike in New England cities.

* * *

The Director of Telegraphs of Venezuela has announced that bids will be asked for the erection of a new high-power radio station at Caracas in the near future.

* * *

Commander R. R. Mann, U. S. N., has relieved Commander J. J. London, U. S. N., as superintendent of Atlantic Coast Naval Communications. He is in charge of both radio and land line circuits.

* * *

Powell Crosley, Jr., president of the Crosley Manufacturing Company and the Precision Equipment Company, Cincinnati, is taking a special radio set with him on his vacation to the wild camping district of the north. He will make some special tests with this equipment.

* * *

The radio baby carriage man has appeared at Forest Hills Gardens, Long Island. He trundles a loop set in a perambulator up and down the residence streets prepared to give an instantaneous demonstration—in fact, the set is sometimes talking when he pulls up to the front door.

* * *

Radio returns of the Dempsey-Gibbons fight, crop reports and bedtime stories filled idle minutes under the big gas bag which carried him to victory in the national elimination balloon race last week, Lieut. Robert S. Olmstead, pilot of the army balloon S-6, said on his return to his post at Middleton. Olmstead and is aide, Lieut. John Shottow of Chanute Field, Ilinois, were over Lake Erie when they began to pick up the broadcast programs.

* * *

Radio service on the Great Lakes formerly handled by the Naval Radio Service has been taken over by the Intercity Radio Company, which has established stations at Cleveland, Detroit and Chicago. Other stations will be opened shortly in all the important lake cities. Ordinary telegraph service between the cities also will be handled. The new installations will operate on 1,800 meters with call letters WTK for the Cleveland station. The station will operate continuously.

Radio service for each of its 1,215 guest rooms will be one of the novel features of the thirty-story Book-Cadillac Hotel, under construction at Detroit, Mich.

* * *

The French Cabinet, on Premier Poincare's demand, has passed a special decree establishing control of the material for radio broadcasting. The decree was presented to President Millerand for signature. The measure forbids the use of radio for anything except Government announcements, ministerial speeches or other matter specifically permitted by the Ministry of Posts and Telegraphs.

Music Radioed From Ship to Shore

(C. Kadel & Herbert)

This is the equipment to be used in broadcasting music from the new S. S. "Albert Ballin's" orchestra as soon as a permit is obtained. Both panels on the wall contain speech amplifiers, which will amplify the music picked up by the microphones. The music will then enter the transmitter to be broadcast to thousands of listeners on shore. Chief Operator William M. Hannemann at the microphone.

RADIO PRIMER

CARE OF THE STORAGE BATTERY IN SUMMER: During the summer months the radio set does not get as much use as it normally would, partly due to the fact that portable sets are used, and also partly due to the fact that the set is not used as much, if it is used at all during the real hot weather.

When you start in the fall, if certain precautions are not used you will be surprised to find that your battery is rapidly deteriorating. Where the battery stands idle, it should always be kept under full charge, regardless of whether it is used or not.

This is because the chemical action that takes place in a storage battery is slowly going on all the time, and if the battery is not kept charged you will find that your battery has "gone dead" on you, or worse yet, the plates will be sulphated (covered with a scaly powdered white coating) and will have to be thrown away. In view of this therefore, always take the precaution to charge it every month.

Another and equally important point in the scheme of things is the fact that the solution should be kept above the tops of the plates. During the warm weather, there is naturally more evaporation than would normally take place in the colder months. Use only distilled water and put enough in the cells every two weeks to keep the plates covered.

Keeping the battery dust proof is also a very good idea. Sulphuric acid has a very bad habit of "creeping." If some is allowed to gather on the composition filler covering the battery you will soon find that it covers the entire top of the battery, creeping to the wood and destroying it.

It is always good practice to cover the terminals and lead strips and all metal parts, such as the lugs that connect the leads of the filament circuit to the battery, with a light coating of vaseline. This is a precaution that will save much time and trouble when you start to use the set later on. If this is not done, you will have trouble with corroded joints, as the fumes of the acid will work havoc with metal if it is not properly protected.

A battery is almost like a human being in some respects. At least once a year you should take the battery to some service station and have it looked over and cleaned out. A lot of sediment generally collects at the bottom of the jars, due to the acid working on the wooden separators and other parts. If this deposit is allowed to stay, it will short circuit the plates and seriously harm the working of the battery.

The Vacuum Tube as An Amplifier

By C. White, Consulting Engineer

IN a previous article I endeavored to explain the difference between the vacuum tube when it was employed as a detector and when employed as an amplifier. For a brief summary, the determining factor was the particular characteristic we were working the tube on that would decide whether the action were that of a detector or an amplifier. Then again, when a tube was to be used as a detector it must have a rectifying quality which is not at all present when the tube is to be used as an amplifier. You will also note from the previous article that when a tube is used as a rectifier it is only the positive impulses that are passed on to the plate circuit, and also that when the grid is positive there is a small current flowing on the grid circuit. This is the reason that a grid leak resistance is used in the grid circuit of a detector tube to regulate the resistance of the leakage path of this current, or of the positive charges on the grid, if you so desire to think of the action in terms of charges. But when the tube is acting in capacity as an amplifier, negative as well as positive impulses must be passed on amplified to the plate circuit, otherwise serious signal distortion would result, to say the least. The grid current, though only appearing on the positive impulses of the grid voltage, would not at all be beneficial since it would flow through the secondary of the amplifying transformer, thus causing the core to be demagnetized, thereby cutting down the volume. To overcome this tendency of the grid to become positive at times it is customary to connect the grid return wire to the negative leg or side of the filament "A" battery. This action causes the grid to be biased with a negative potential which does the same thing graphically as shifting the grid variations from the dotted line position, as shown in Fig. 1, to the solid line position. It means that the grid will remain negative at all variations of the grid potential, unless the positive throw of the grid alternation is greater than the negative bias, and under such circumstances an additional negative potential bias must be obtained from a "C" battery as illustrated in Fig. 2. If, perchance, a high "B" or plate battery voltage is employed the grid will have a strong tendency to become positive at certain times, or when amplifying certain notes. This means that there will be a grid current for those particular notes and no grid current for all the others—hence distortion will be present. To prevent this a "C" battery is used when high plate voltages are used. The advantage of the latter is that the amount of amplification is greatly increased with an increase in plate voltage provided we keep the grid negative at all times and we do not overload any part of the circuit.

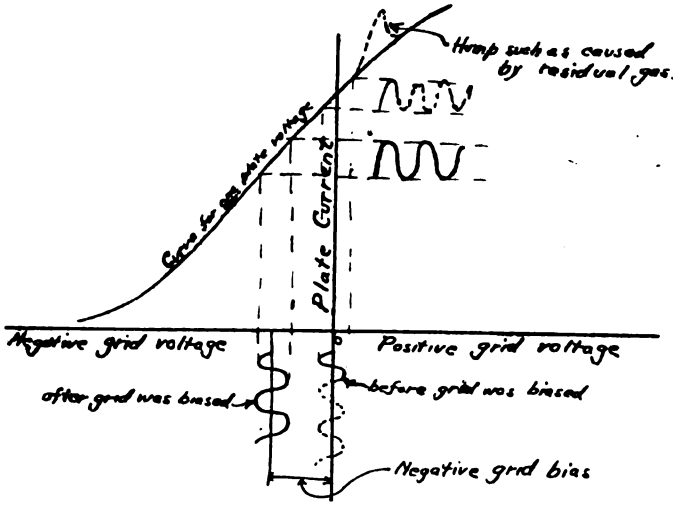

Fig. 1—Results of laboratory tests on a soft tube.

The old question as to why a soft tube makes a good detector and a poor amplifier arises. A soft tube is one in which a small amount of residual gas still remains. When the filament is heated there is an electron emission from the material of the filament itself and another entirely separate electron action caused by the residual gas. The action is quite analogous to boiling a pot of fluid that contains ether and water. Of course, you would expect that the ether would boil off at a different temperature than the water. The same is true of the gas in the tube. The combination of the two actions makes the tube very erratic or "sensitive," which fact is easily seen in a laboratory test of a given tube by a hump or lump appearing on the characteristic, as shown by the dotted line on the curve in Fig. 1. A lumpy curve is no more desirable for amplification than a rough road is for motoring. Strange to say, the lumps do come in handy when a tube is to be used as a detector, but do not be mislead into the belief that only a soft tube will act satisfactorily as a detector. This fact, though very common a year ago, is now falling into the background because experience has shown that a hard tube will often do the job just as well and in some cases better than a soft.

There is always a bridge from the theoretical side to the practical. Remember that I said that when the grid was negative that no grid current flowed. This fact is not entirely true for at all times there is a very small grid current, although it is to be conceded that the amount flowing when the grid is positive is many times larger. Then again, experience has taught that a constant input impedance for an amplifying circuit is very desirable; hence the practice of placing a variable grid leak across the secondary of the amplifying transformer in order to provide a constant input impedance once it is adjusted to the correct value. If the secondary is left open the input impedance can vary anywhere from a known value to infinite value, depending upon the insulation resistance and other constants of the circuit. With some transformers you will find that a grid leak in the position as indicated in Fig. 2 certainly takes a lot of noises and crackling out of the signal without cutting down amplification to a marked degree. If you now have an amplifier and it is very noisy try a grid leak across the secondary and a "C" battery. Try reversing the secondary terminal connections to the transformer and note the difference Little tricks will often enable you to locate trouble as well as improve your outfit.

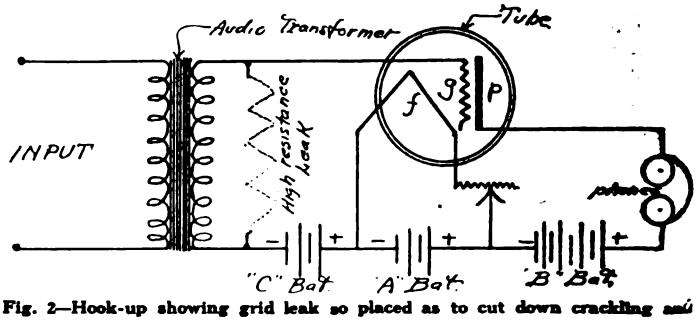

Fig. 2—Hook-up showing grid leak so placed as to cut down crackling and other noises.

Second Convention of Radio Amateurs Meets in Chicago, September 12-15

CHICAGO, ILL.—All "Hamdom" will meet in Chicago!

The largest gathering of radio amateurs in history is scheduled for this city September 12 to 15, when the Second National A. R. R. L. Convention will be held here under the auspices of the Chicago Radio Traffic Association with headquarters at 959 Rookery This was announced last week following receipt of information that Chicago had been selected as the scene of the convention by the American Radio Relay League Board of Direction at a meeting in New York City.

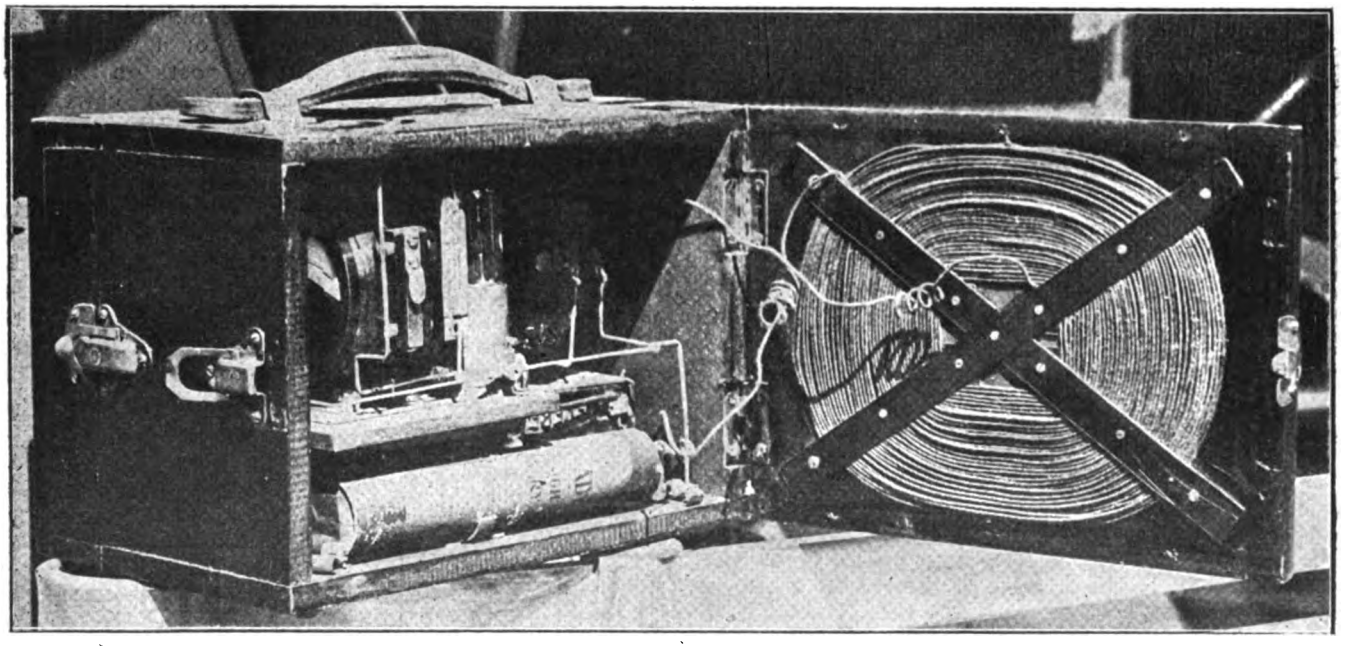
DX fans all over the country and Canada, from New York to the Golden Gate and Ontario to the Gulf, many of whom communicate with each other nightly over thousands of miles through the A. R. R. L. relay system and who know each other best by their call letters, will here meet face to face for a discussion of their special problems.

There has been but one other such convention, held here in 1921, and the tremendous strides in amateur radio since that time and with it the growth of the amateurs' representative body, the A. R. R. L., will make the coming event one of great moment to all amateurs and to the radio public in general.

Since that first meeting amateurs using low power have sent their signals across the Atlantic and Pacific Oceans, their transmitters have worked stations in Australia and New Zealand and their calls have been heard in South America and Africa. One of their number is now radio operator on Captain Donald B. MacMillan's schooner "Bowdoin" bound for exploration in the Arctic.

With their transmitting stations reducing the size of the globe month by month, amateur interest is running high and the coming convention will carry this spirit of progress in review.

A Light Weight Portable Receiver for Automobile Use



This picture shows an interior view of a new auto portable receiver built by L. J. Miller, of Brooklyn, N. Y. The set weighs nine pounds and is complete with batteries and head phones. It operates on a 7x10-inch loop incorporated in the set. It will receive up to 25 miles in the city and 50 miles in the country.

Condenser Substitute

SOME time during the operation of your transmitter you have had the hard luck of blowing a condenser, just when you needed your transmitter most. No doubt you sat there and made the surrounding air a deep navy with your remarks.

The next time it happens (we don't wish it on you, but accidents are liable to happen) don't cuss. Simply get a mason jar and a test tube, or smaller jar which will fit inside of it, and fill both three-quarters full of salt water. Immerse two leads in both jars, and you have a condenser. It is a makeshift at best, but it has saved many a futile hour hunting for a glass plate to mend the old one.

Are You Undecided?

MANY times the fan sees a circuit that he wishes to try, or wants to build a set and doesn't know which type to tackle. Will it be a triple circuit, double circuit, single circuit or reflex? If he has no experience in set building, the last one that he ought to tackle from a practical standpoint is the reflex. But if he is looking for selectivity, he ought to give the triple circuit sets careful consideration. If he wants volume he should tackle some simple single circuit, but first give a thought to the neighbors, because most single circuits can cause more ruction in a neighborhood than a mouse at a "sewing circle."

A Crystal Receiver and Wave Meter Combined

By Kenneth Malcolm, A. I. R. E.

A WAVE meter serves the purpose which its name implies—it measures waves. Not long ago the writer was asked how anyone knew that a station had a wave length of so many meters, since the waves themselves were imperceptible to any of the senses, and they could not be measured with a rule, as visible material things could be measured. We cannot see amperes or volts or watts, yet we can measure them very accurately with instruments that are made for the purpose—and radio waves can be measured in the same way by instruments.

The length of a radio wave depends upon its frequency, and the frequency of a wave depends upon the product of the inductance and the capacity in the circuit. By knowing the inductance and the capacity of the circuit we know the frequency, and by knowing the speed at which the waves travel, we can easily calculate the wave length—simply by dividing the speed by the frequency. The waves travel through the

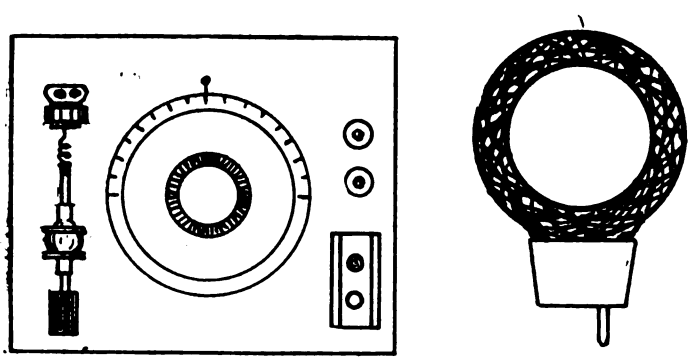

Fig. 1. Panel layout and coil for a crystal receiver and wave meter combined.

ether at the speed of light, or 300,000,000 meters a second. If we have the circuit constants of such a value that they will give a frequency of 500,000 waves a second, the process of simple division gives us the figure 600, which is the length in meters of a single wave.

To simplify the process of calculation, an inductance coil of known value is incorporated in a circuit with a variable condenser, and the combination is calibrated from standards and called a wave meter. Some of these instruments read directly in meters, while others must be used in connection with a calibration chart, which gives the meter values for the different scale readings of the condenser.

It is not absolutely necessary to have a wave meter when you have only a receiving set, but its use would prove interesting, as well as aiding in the calibration of the set and in tuning.

The meter to be described can be made quite easily and at a very moderate cost, and besides being a measure for wave lengths, it may be used as a very fine crystal receiver for use with a large loop; a loop such as described a short time ago in this magazine.

The necessary parts are few and include: a good variable condenser of .0005 mfd. capacity; the parts for a crystal detector; four binding posts; a pair of phones; a phone condenser of a capacity of about .002 or .003 mfd.; a DL coil plug socket; a DL-35 honeycomb coil; an insulating panel 3/16-inch thick, seven inches long and six inches wide; and a box of a size to fit the panel and about four inches deep.

Too much stress cannot be laid on securing good parts—those whose constants will not easily change with weather conditions and with handling. The condenser should be of solid construction, with heavy plates that are held firmly in position and well spaced. The DL coil should be perfect, with no loose wires and with the plug well secured. The detector may be of most any type, but the one illustrated is convenient and will give good service. The parts may be bought for very little, or they may be demounted from a mounted detector. The box should be of hard wood, and of a depth sufficient to take the particular condenser which you are able to get.

With all the parts at hand, you can start to lay out the panel for drilling. The arrangement shown in the drawing is very good, both for accessibility of instruments and making short and direct connections. If you wish to use the instrument solely for a wave meter, you may omit the pair of binding posts on the right hand side next to the plug socket, for these were designed to admit the outfit being used as a receiving set with a loop, or connected in the secondary of a loose coupler.

After all the holes have been drilled, the apparatus may be assembled. Then comes the wiring. Use heavy wire for this—say, No. 18 or 14—and make the connections direct, and solder them all. The circuit for the meter is shown as the circuit in Fig. 2, in which the inductance A is included. The two right hand binding posts are connected in parallel to the plug socket. The lower pair of posts are for the phones.

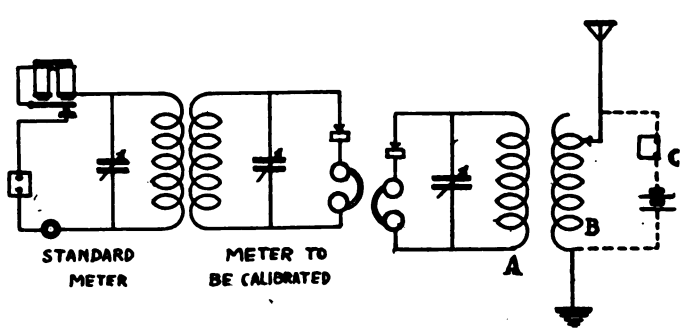

Fig. 2. Arrangement of apparatus for measuring incoming waves. Fig. 3 (at the right). Method of calibrating instrument from a standard.

When this has been done, your wave meter is complete, except for the calibration. This may be done with the aid of a standard wave meter, or, at least partly, by the assistance of the standard waves that are sent out periodically by the government. The former mentioned method is the easiest and the most satisfactory, and will be described. The standard wave meter should have a buzzer exciter, and the two meters should be placed in the relationship to each other as shown. That is, the coils of the two meters should be in inductive relation to each other. The exact degree of coupling can only be determined by experiment, but it should not be any greater than is necessary for

(*Concluded on next page*)

Digitized by Google

(*Concluded from preceding page*)

good audibility, for the looser the coupling, the greater the accuracy that may be obtained.

To begin the calibration, set the standard meter at some arbitrary wave length, such as 250 meters. Start the buzzer going, and adjust the detector of the meter to be calibrated. Then vary the condenser until the maximum response is heard in the phones. This point is the point of resonance, and the degree on the scale of your condenser should be noted on a piece of paper, beside the wave length; such as 250 meters, 30 degrees. Go through this operation with a number of other wave lengths, marking down each one on the paper. Try about 10 points. Also determine the maximum and minimum wave length that is possible with your particular coil and condenser. If a higher wave length is desired than is obtainable with your DL-35 coil, use a larger coil, and make a separate calibration list for this coil. It might be here mentioned, that after a particular coil has been calibrated in connection with the wave meter, it should always be used, and not changed for another of supposedly the same inductance value, for a very slight difference in the coils will make a considerable change in the accuracy of the meter.

When you have secured the scale readings for about ten wave lengths, you can make a *calibration curve* on a sheet of cross-section paper. This paper you may buy in any store where draftsmen's materials are sold; or can make it yourself, by ruling horizontal and vertical lines on a sheet of paper, forming a large number of squares, somewhat as shown in the sample in Fig. 4. The curve is made by first dividing the horizontal lines as scale readings on the condenser and the vertical lines as wave length readings. Now, at the intersections, mark dots, for each of the test readings that were taken. For instance, the scale at 20 gave a meter reading of 175—mark a dot at the intersection of the vertical line 20 and the horizontal line 175. The scale at 70 gave a reading of 450 meters—mark a dot at this intersection. And do the same with the other readings, as shown. Then, when this is done, draw a line connecting all these dots. This will give you at a glance the wave length for any scale reading on your condenser.

Next comes the practical use of the meter, in measuring waves. Fig. 2 shows how the apparatus should be arranged to measure the wave length of a wave that is coming in through the aerial. In this instance the apparatus connected by the dotted lines is not used. B is the primary of your coupler, and A is the wave meter coil. Get these in inductive relation to each other, tune your set in the regular way, and then adjust the wave meter for maximum response. The maximum audibility point indicates resonance, and by checking up your dial reading with your calibration chart you can tell the wave length.

The value of knowing the exact wave length cannot be overestimated, for with this knowledge the receiving set can also be calibrated; which means that tuning comes out of the realm of guess-work and becomes exact. To calibrate your set, you have simply to tune in a station, ascertain its exact wave length, and either mark the dials, or else mark their relative positions on a sheet of paper, or in a little book for future reference. Or, instead of tuning in a station, you may connect a buzzer and battery across your primary coil, as shown by the dotted lines in Fig. 2; then set your wave meter at some arbitrary wave length, and adjust the coupler primary switch until maximum response is obtained. When the primary is adjusted to resonance, the other circuits may be tuned to it, the buzzer still going.

The wave meter shows its real value in tuning a transmitting set, for here we more than have a wave of an exact length. The process that must be gone through is identical with that of tuning a receiving set, except that the power is supplied to the set from a small spark coil, a transformer, or a vacuum tube, instead of incoming signals. For best results, each circuit should be tuned separately, and then finally both together. First, the closed circuit is tuned with the secondary, or open circuit, out of inductive relation. Then the open circuit is tuned, without being coupled to the closed circuit. Finally the normal coupling is used, and the circuits slightly readjusted as required.

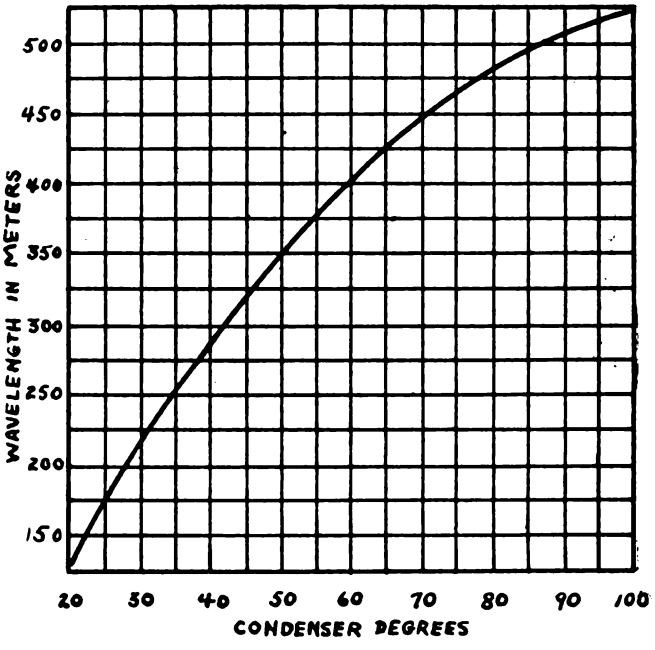

Fig. 4. Specimen calibration curve.

Texas Amateur Station Makes Record

HARTFORD, CONN.—Relaying of private messages by amateur radio telegraph stations of the American Radio Relay League is holding up well during the summer. The report of F. H. Schnell, traffic manager, shows a total of 34,648 messages handled during June by North American amateurs. The messages handled by spark transmitters were only six per cent. as compared with 94 per cent. using continuous wave.

Despite the tremendous amount of static which prevails in the Gulf states at this season, the best individual record was made by Roy S. Lay, operator of official A. R. R. L. relay station 5TM, at 110 Hubbard St., Yoakum, Texas.

Have You Made Sure?

DO you understand the polarity of your phones? Phones always work best when a definite lead is connected to the positive side of the B battery. If you do not know, ask someone who does and note the difference. The same applies to loud speakers, especially the ones that do not need a field battery.

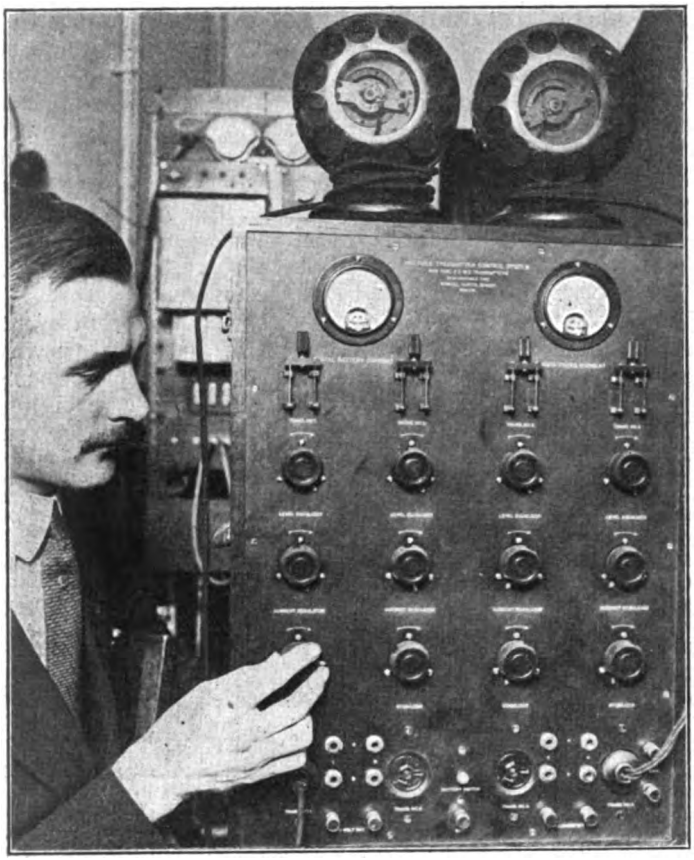
It's Wonderful the Way Radio Pe



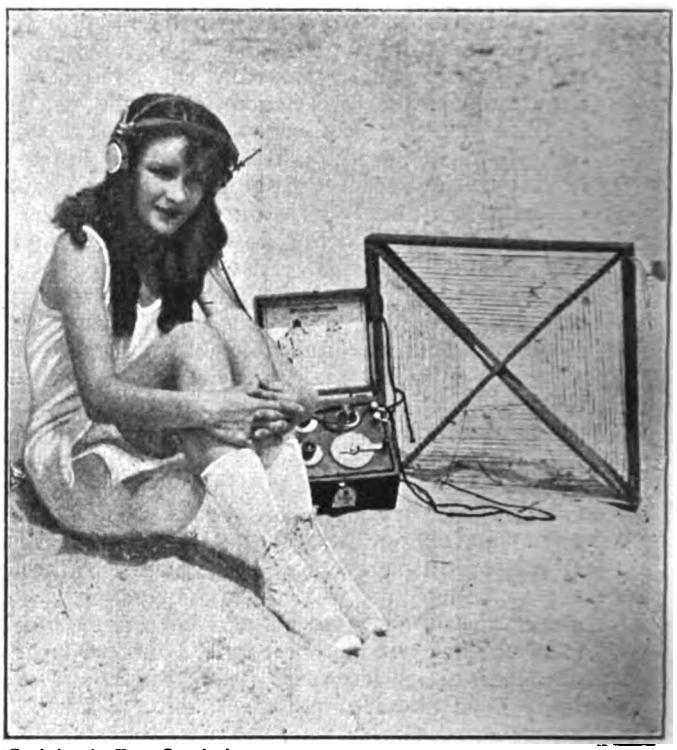
(C. Kadel & Herbert)

Station WNAC of the Shepard Stores at Boston, has developed a system whereby organ music, band concerts, etc., can be broadcast with all tones preserved intact. Most of the low tones of a pipe organ or orchestra are lost when broadcast by radio, but by means of this device four microphones can be used simultaneously to pick up the music. The picture shows Chief Operator Samuel Curtis who contrived the device.

Captions by Robert L. Dougherty

(C. Joel Feder)

A charming interior with the radio set artistically arranged. Mother and daughter are apparently enjoying a program which interests and pleases. The set is equipped with the Sleeper "Monotrol."



(C. Atlantic Foto Service)

Many summer residents of Atlantic City, N. J., carry their portable sets with them to the beach. Miss Beryl Williams is one of these. Having tired of the ocean waves she is resting on the sands and picking up something interesting via radio.

(C. Kadel & Herbert)

Phil Hughes and Willie Keeler have finished a strenuous eighteen holes and are now listening in while resting for a final round. Not only in the club house but on the course radio is gaining in popularity at golf clubs.

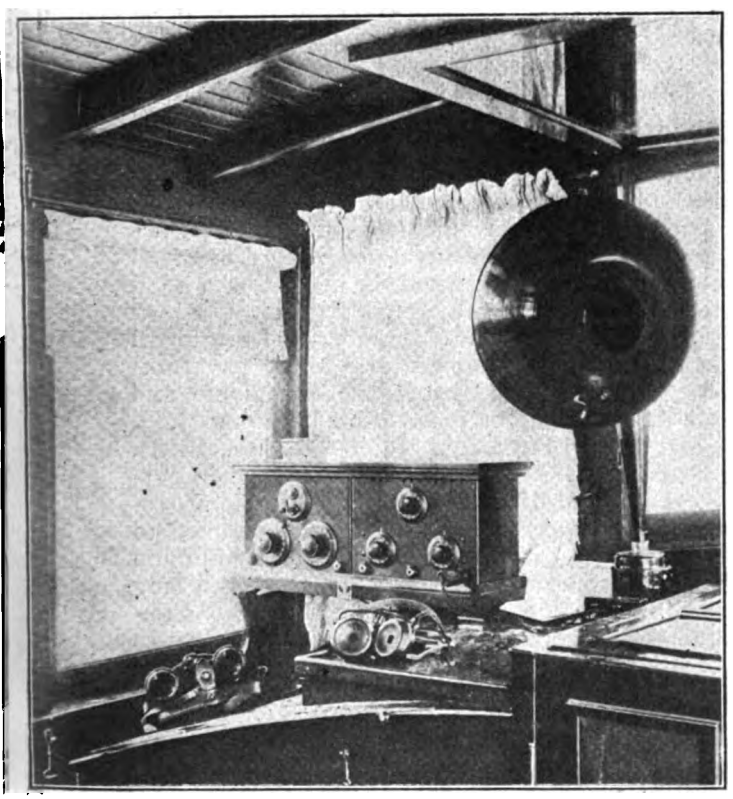
(C. P. & A. Photos)

Capt. Gypsy Pat Smith, famous English revivalist, is recovering from an operation at a nursing home in Edinburgh, Scotland. His hours of convalescence are lightened by listening in to radio programs.

rmeates the Whole Wide World

(C. Kadel & Herbert)

Charles Hall, of New York City, using a bed spring aerial and an interesting combination of a neutrodyne and tuned radio frequency, easily receives WOC, WOAW and WDAP right in mid-summer. Mr. Hall has a unique cut-off arrangement in this set by which he can use a crystal detector or one or more tubes.



(C. Kadel & Herbert)

Here's the neat receiving set on the beautiful yacht of Harry C. Stevenson, of Rochester, N. Y. The set is grounded to the shaft of the engine. For an aerial he uses a rubber insulated cable about 75 feet long with the outer end carefully sealed and insulated. This is tossed in the water and drags after the yacht. It is said to work well.

(C. Photonews, N. Y.)

New York firemen haven't much spare time, but with a pool table and a radio set presented by a friend, the men of Engine Company No. 8 are well fixed to enjoy their leisure. Captain Joseph Donovan is tuning in.

(C. Underwood & Underwood)

Harry Schwartz is here shown giving pointers on the construction of radio sets to Boy Scouts at Camp Spence, Bear Mountain, N. Y. A day's tramping in the forest, a lesson in woodcraft, a cooling plunge in the lake or stream, dinner and a radio program—well, it's good to be a Boy Scout!

(C. Keystone View Co.)

Mlle. Suzanne Langlen, the greatest woman tennis player of them all, is here shown broadcasting tennis instruction to thousands of fans. This is an unusually quiet pose for the tennis star.

Scott Clariphone Kills Static

By Carl H. Butman

THE Scott clariphone, an acoustical device for the elimination of static, will undoubtedly be one of the greatest advancements in radio communication when perfected, naval radio experts declare. Through its selective action the clariphone subdues the mechanical sounds of discontinuous character and sustains the continuous notes as well as uniformly pitched sounds, enabling stations transmitting from a long distance through static interference, to be read much more easily.

Although the inventor, Chief Electrician Wm. J. Scott, U. S. N., began work on this static eliminator eleven years ago and filed an application in the Patent Office in January, 1921, little except the name of the filtering device has been made public. Since successful tests at the Bureau of Standards and at Naval Radio Central at Washington, naval officials have decided to release certain facts regarding the unique apparatus in the interest of those who are also fighting summer static in an effort to perfect radio communication.

While the clariphone is still in its experimental stage, the results obtained from the tests in Radio Central seem to indicate that the entire elimination of static may be hoped for in the near future, one naval expert asserts. Without going into the technical details, and the operation is complicated, the writer can vouch for the fact that the instrument works. While in one of the receiving stations on the third floor of the Navy Building a few days ago, we tuned in NPG, San Francisco, which we heard faintly through bad static. By changing from the set of head phones on the regular receiving set to a pair connected with the clariphone, a remarkable improvement was at once noted; the static was reduced materially and the distant signals from 'Frisco came in clearer and sharper. Dispatches from the naval stations NBA, Balboa, and NPL, San Diego, were also read with ease when the clariphone was connected in, whereas the dots and dashes were difficult to distinguish through the phones directly on the receiving set.

Mr. Scott also hopes to be able to eliminate all interference from nearby stations using wave lengths which are close to the wave length that the instrument is tuned to.

The apparatus consists of a large metallic chamber or tube about four feet long and 18 inches in diameter, with adjustable ends slightly smaller in diameter. From the chamber eight smaller tubes or "telescopes" project radially in pairs. Each "telescope" contains a watch case telephone receiver used for introducing the radio signals received from the radio set into the receiving chamber. The incoming sound is then passed through the chamber acoustically, where it is broken up several hundred times, the inventor explains, by the internal arrangement. All of the static is absorbed by over 10,000 separate pieces used in its construction. Exactly how is not divulged. To a lesser degree, the sound waves themselves are also absorbed in the filtering process. A weaker but a clear note is picked up by four microphones, two on the top of the cylinder and one on each end. The microphones are connected in parallel to the primary of a transformer, the secondary being connected to a head set where the operator receives the outcoming signals after the static is eliminated. The sound of the signals may also be heard through two acoustical phones also attached to the top of the apparatus. When the outcoming sounds are found too weak, they may be amplified in the usual manner.

Whatever the internal acoustical mechanism may be, the Patent Office recognizes it as a pioneer invention, and Mr. Scott has patents pending in the United States and several foreign countries. The clariphone will operate for the elimination of static either in radio telegraphic or telephonic communication.

To date only one instrument is in operation, but another with some improvements is under construction, it is understood. The inventor is now engaged in working out a practical method for producing a good audible tone to the sound waves which leave the four microphones on the cylindrical chamber and are heard in the head phones by the operator. Many naval experts have examined and tested the clariphone and have made helpful suggestions. Chief Gunner J. J. Delaney and Chief Radiomen John Gilmore, E. H. Wilkinson and E. L. Cash are aiding Mr. Scott in perfecting the radio end of his invention. With improvements now under way the apparatus can be tuned to maximum strength wireless signal and minimum strength of atmospheric disturbance, which goes a long way toward improving long distance wireless communication. The apparatus is not yet available to owners of private receiving stations nor amateurs, because of its cost, but future developments and production on a large scale may make it a practical adjunct to general radio reception.

The navy is particularly interested since apparatus of this sort could be used on its ships and shore stations, particularly in the tropics where static interferes greatly with communication. Lighter sets for adoption in airplanes and submarines for the elimination of various forms of noise are also being considered.

Consider the Others

MANY operators of sets like to tune in long distance stations. Many of the sets are single circuit regenerators that oscillate to beat the cars, and re-radiate everything. When tuning in, consider the other fellows in the surrounding district and do not tune by the beat method. It is only through everyone co-operating in this matter that any help can be had on the worst problem of interference that has yet come up. Think it over, fellows, and tune in right.

Radio Dealers, Do You and Your Salesmen Set the Right Example?

You believe, of course, that radio is a great thing, and that every home should be radio equipped.
Have you a radio set in your home?
Have your employees sets in their homes?
Think it over for a moment.
Salesmanship begins at home!

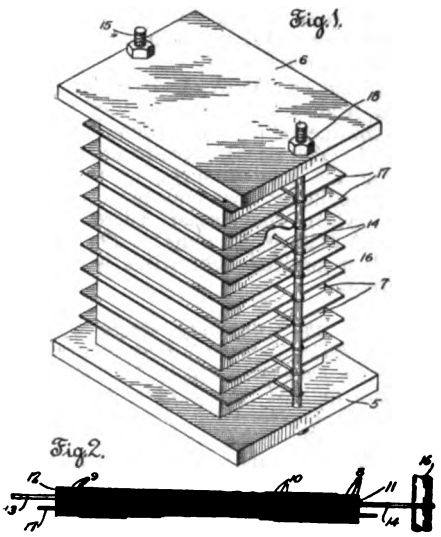
Latest Radio Patents

Dubilier's Electric Condenser

No. 1,455,781: Patented May 22, 1923. Patentee: William Dubilier, New York, N. Y.

The object of this invention is in the provision of an improved condenser or electrostatic accumulator in which induction takes place through its mass, causing a difference of potential energy at its terminals.

Such condensers are usually composed of a plurality of thin sheet metal or metallic foil layers separated by a non-conducting material, such as mica, paraffine paper, etc.,



Dubilier's improved electric condenser.

the opposite layers forming terminals from which current is received and delivered.

In condensers in which mica is used as the dielectric, where the size of the mica sheet is limited for commercial reasons, if large capacities are required, say for example one microfarad, the number of layers and sheets must be increased.

A large number of sheets must be built up into a single unit and if mica sheets of for instance 2x3 inches by .003 be used, a one microfarad unit will be about two inches thick.

With the use of commercial sizes of mica in order to get a microfarad, almost 1,000 sheets will be used in the unit. We then will have about 500 layers piled on one side electrically connected together and 500 layers on the other side of the pile electrically connected together.

If there should be one defective mica sheet in this pile which for some reason or other should break down after the unit is assembled, the entire condenser becomes defective and it becomes expensive to repair.

If however, we should make small groups or sections of say 50 layers and then connect these 20 groups or sections in one pile with insulated separators between each group, and the group containing the defective sheet should break down, the whole unit of course will be defective but it will be much easier to repair by taking out that single group or section which contained the defective sheet.

If however, these groups or sections were connected in parallel through a thin or light conductor which is easily fusible, as for instance a small lead wire, then if one section or a sheet in one section should break down, all the remaining sections that are connected in parallel will momentarily discharge through that broken down section with the result that a heavy rush of current will surge through that single section, it acting somewhat the same as a spark gap across a condenser, with the result that the heavy current will rush through the single light conductor connecting the defective section.

This conductor will fuse thus opening the circuit to the defective group or section, similar to the action of a fuse in an electric light circuit, automatically disconnecting the defective section, with the result that the remaining sections remain in circuit and continue to function.

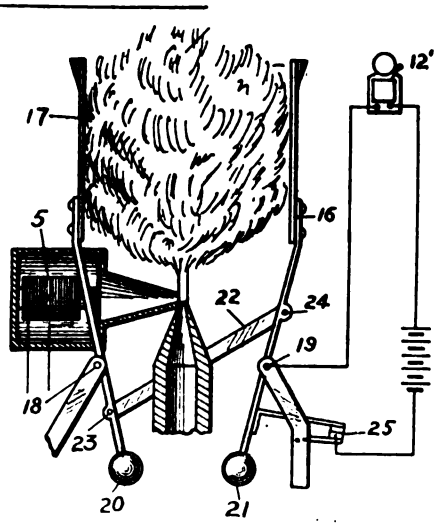
This invention is designed to overcome the defects as above stated, in that, should the insulation fail between any of the plates or sheets constituting one of the several series or groups of condenser elements, those remaining in groups will continue to function effectively.

Electric Indicator for Vibrations of the Air

No. 1,454,965: Patented May 8, 1923. Patentee: Elmer A. Sperry, Brooklyn, N. Y.

This invention relates to a method or means for indicating periodic wave motions of the air which are not readily detected by the ear. Such wave motions may consist of feeble sounds or of wave motions of a frequency above or below that of audibility. The invention has especial relation to the detection of feeble wave motions produced by radiant energy receivers, such as used in wireless telegraphy.

According to my invention I make use of a sensitive fluid jet such as a manometric flame which, as is well known, consists of a long splindling slender gas flame. Such a flame when acted upon by sound waves or the like instantly changes its form by first squatting or greatly shortening its length and then broadening or flaring out laterally in all directions as though effected by a blast or a draught. The moment the vibration ceases the jet resumes its former proportions. Adjacent the flame I place some



Sperry's electric air vibration indicator.

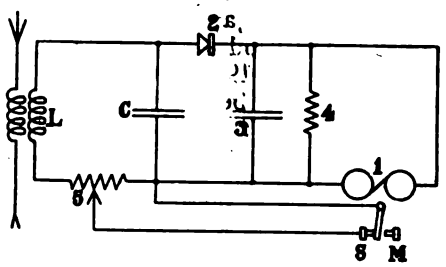
form of sensitive electric apparatus brought into operation by changes in the form of the flame to operate an indicator.

Wireless Telegraph Receiver

No. 1,459,896: Patented May 22, 1923. Patentee: L. B. Turner, London, England.

In high-speed signalling by wireless telegraphy with long waves and with receiving circuits of small damping, limitation of speed is imposed by the slowness with which the oscillation produced in the receiving circuit during a dot or dash of the signalling code dies away during the subsequent space of the signalling code. The rate of dying away is increased if the damping is increased; but the amplitude reached is then decreased, which implies a decrease in the sensitiveness of the receiver.

The present invention consists in the provision of means whereby the received signal (dot or dash, in the Morse code), upon reaching an amplitude competent to operate the receiving instrument, introduces additional damping into the receiving circuit;



Turner's wireless telegraph receiver circuit.

which additional damping is maintained as long as the incoming signal is maintained but automatically disappears, or substantially disappears during the next spacing period. The automatic increasing of the damping is hereinafter referred to as "curbing"; and curbing is said to begin when the additional damping is first introduced, and to end when it is removed. The curbing is preferably maintained throughout as large a proportion of the spacing period as possible. Under these conditions, the decrement of the uncurbed receiving circuit may be made small, thus favoring the growth of the oscillation in the receiving circuit up to its operative amplitude; the curbing thereupon effected imposes a restriction on the further growth of amplitude; and, if the curbing is maintained for a time after the cessation of the incoming signal, the rate at which the amplitude dies away towards zero is greater than that corresponding to the decrement of the uncurbed circuit.

Curbing may be effected in all or any of the receiving circuits, including the antenna circuit itself; but the arrangement preferred is one in which the antenna is relatively highly damped, and has coupled to it a circuit of specially low decrement to which the curbing is applied. The low decrement of the uncurbed receiving circuit may be arrived at in any known way, with or without the aid of retroactive thermionic triode circuits associated with the receiving circuit for the purpose of reducing its decrement in the well known manner.

Another Subscriber Likes the Diet We Provide

EDITOR, RADIO WORLD: Enclosed please find check for six dollars. Kindly send RADIO WORLD for another year, beginning July 14, 1923, taking care not to miss sending me any of the fifty-two issues. I have a copy of all issues to date, and make the fur fly if the mail doesn't bring each copy on time. RADIO WORLD is breakfast, dinner and supper to me.

Yours very truly,

L. HAMILTON ADAMS, JR.

Answers to Readers of Radio World

Kindly advise me if the enclosed radio-frequency circuit can be used with the De Forest coils and triple mounting?—Arthur Peterson, Rockaway Building, South Ozone Park, L. I.

You could not use the De Forest coils and mounting with this circuit without changing it entirely around. It is regenerative as it stands, and no benefit would be derived in changing it.

* * *

I recently constructed a reflex set using one tube and a crystal detector, with a honeycomb coil and condenser as a radio-frequency transformer. I can take the crystal detector out of the circuit and still hear signals. What is the trouble?—Charles Leslie, Box 134, San Francisco, Cal.

It is quite evident that, in the construction of your receiver, you made some mistake, otherwise you would not be able to hear signals when you remove your crystal detector. Go over your connections very carefully, and make sure that your leads do not run parallel. See that everything is connected right, or, better yet, rehook your set. Be extremely careful about your battery connections. You are using your tube as a rectifier (detector) and the current is leaking through some of your leads. Reflex sets require very careful construction in order to work correctly, and you should not go about the construction of these sets unless you are prepared to take every care and precaution and plenty of time in the wiring and use only the best of parts.

* * *

I am located just on the outskirts of Rochester, N. Y. I have great trouble getting distant stations to the South and Southwest, although I use five tubes and can get the far Western and Northern stations. I should be able to get greater distances as the set operated perfectly when up in Albany, and stations all over pounded in; but where I am located I cannot get anything but at one location.—Gene Fowlman, 132 Main Street, Rochester, N. Y.

It is quite evident that you are in a "dead spot," as can be seen by your explanation. Nothing can be done to alleviate your trouble as there is some condition existing which is causing it that you have no control over. It may be that your set is located in a district that has some steel structures that are robbing you of your signals, or it might be some other cause. Suggest that you ask some of your radio friends in Rochester and see if they are bothered in the same manner. Writing your troubles to the Radio Division, General Electric Co., Schenectady, N. Y., would probably give them some information that they would be glad to investigate.

* * *

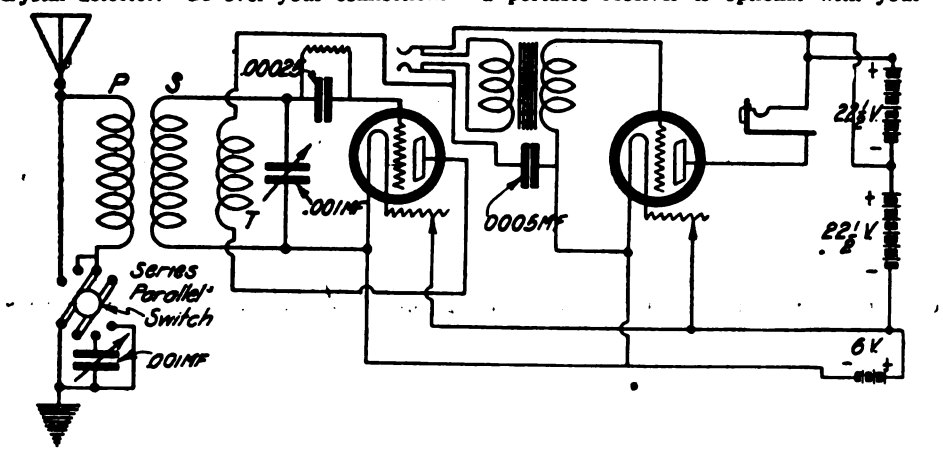
Do the call letters signify anything particular outside of a certain station? Can each station pick its own call letters?—A Radiofan, Cincinnati, Ohio.

The call letters are given as an indication of each station and do not have any valid meaning. The call letters are assigned by the government, and are arranged alphabetically and given in order.

* * *

Will you publish a circuit diagram of a receiver capable of receiving from 150 to 25,000 meters using two tubes? It is to be a portable receiver.—A. B. June 11 Fairview Avenue, New Brighton, Staten Island.

The circuit you wish is published herewith. The fact that you want to make it a portable receiver is optional with yourself. We can only furnish the circuit diagram. The design of the set is up to you.



Three circuit honeycomb coil set with one stage of amplification, requested by A. B. June. A series parallel switch is used to give a wide range of adjustment with but few primary coils.

* * *

The light for the house and barn is furnished by a 32-volt, gasoline-driven generator. Can I use this to light the filaments and supply the plate voltage of the tubes of my set?—Charles Customer, Spring Lake, N. J.

You can do this by the use of proper resistances and a filter system to remove the commutator ripple. Be very careful when using this voltage, however, or you will blow out your tubes. In the long run it will be safer if you use the regulation battery for filament supply.

* * *

I purchased a three-tube set made by the ..... company last winter. I have heard that, during the summer months, distant reception is impossible. During the winter my range was 2,000 miles, yet now I can only get extremely local stations within a range of 50 miles and with extremely poor volume. Should my reception and volume be cut down that low?—J. S. Domidion, 155 West 45th Street, New York City.

Your reception will not be as great in the summer as in the winter, but the enormous cut in reception that you notice probably is not due to this condition. Examine your antenna, especially your insulators, and see if they are not shorted by dust and dirt. Clean them thoroughly and look at your lead-in connection. Examine your ground connection thoroughly and try using another ground in connection with it. Examine your phones carefully and test them, if possible, against another pair to see if it is the phones or the set itself that is at fault. Renew your B batteries.

* * *

I recently constructed the Grimes' inverse duplex receiver as per instructions in Radio World *for June 2. Will it be possible for me to operate three loud-speakers on different floors of my house with the aid of a single power amplifier in connection with this set? Should I lay the wires in conduit? What size wire should be used in wiring for this purpose?—John Guilbert, 232 West 4th Street, Newark, N. J.*

You should be able to operate three loud-speakers from a single power amplifier on the set you mention. They should be wired in parallel. You do not have to use conduit in wiring the loud-speakers, as the tenement and building laws only prescribe that method when commercial currents are being used (110 or 220 volts). The double stranded or braided light wires will serve this purpose.

* * *

What is the consistent range of the De Forest reflex loop set? I have been told that signals have been received 2,800 miles, but wish to find out before going any further.—E. L. MacNabb, 3 Water Street, Quebec, Canada.

We cannot specify the range of any receiver as there are too many variable factors which affect the range of such apparatus. However, it is perfectly possible to cover the range you mention with such a receiver, conditions being favorable.

* * *

Concerning the WD-11 circuit described by Ortherus Gordon in Radio World *for Jan. 20. I cannot get it to work properly. There seems to be no difference whether I have the tickler coil one-half or three inches away, it does not vary the tuning. Also, my antenna condenser does not vary the wave length.—Eugene L. Kills, 524 W. Fourth St., Cameron, Mo.*

Reverse your tickler connections and make sure that you have it wired correctly. This is the conventional single circuit tuner, using a tickler in the plate circuit to produce regeneration. As to your condenser, there is no reason in the world why it should not vary the wave length if it is properly inserted. Make sure that it is not short-circuited. If it is this would cause the trouble that you are experiencing.

* * *

Is it possible to lessen interference by the use of resistances in series with the antenna inductance? I am bothered by considerable inductive hum from the feeder lines of the railroad that run parallel to my antenna.—Morris Muller, East Philadelphia, Pa.

Putting resistances in your antenna circuit would not tend to lessen the induction hum you notice. Place your antenna at right angles to the feeder lines and use a filter coil such as is described in Radio World *for January 20, page 20.*

* * *

Is it possible for me to accommodate the neutrodyne principle that is so popular with the set shown herewith?—Louis Plantaka, 244 East 72d Street, New York City.

It is impossible to apply the neutrodyne principle to the receiver you show. It is a three-circuit regenerative, and if you kill its regenerative action you are losing the advantage of the circuit.

MAGNAVOX

Radio in Summer

THE man who purchases a Magnavox for its clearness of reproduction, finds additional advantages in its use which contribute greatly to his enjoyment of Radio.

For instance, due to its extreme sensitivity, the Magnavox can clearly reproduce signals which otherwise would be indistinguishable.

This means a great increase in distance range—more stations brought within the Magnavox owner's reach.

Magnavox Reproducers and Power Amplifiers can be used with any receiving set of good quality. Without Magnavox, no receiving set is complete.

Magnavox R2 Reproducer and 2 stage Power Amplifier (as illustrated) **$115.00**

R2 Magnavox Reproducer with 18-inch curvex horn: the utmost in amplifying power; requires only .6 of an ampere for the field **$60.00**

R3 Magnavox Reproducer with 14-inch curvex horn: ideal for homes, offices, etc. . . . **$35.00**

Model C Magnavox Power Amplifier insures getting the largest possible power input for your Magnavox Reproducer.

AC-2-C, 2-stage, $55.00
AC-3-C, 3-stage, $75.00

A clearer Radio voice, sounding above the tumult of vacation time

WHEN days are spent in summer's outdoor playgrounds, Magnavox needs only an instant's notice to supply dance music, sporting news or entertainment for all.

Open places test impartially the real quality of Radio reproduction—with Magnavox equipment your receiving set will give superbly adequate performances, indoors or out, the year 'round.

Magnavox products can be had of good dealers everywhere. Send for copy of unusual booklet.

The Magnavox Co., Oakland, California
New York: 370 Seventh Avenue

Radio Literature Wanted

Manufacturers of and dealers in radio apparatus and accessories are notified that literature and catalogues describing their products have been requested, through the Service Editor of RADIO WORLD, by the following:

Morker Electric Co., 340 St. Mary St., Phoenixville, Pa. (Retailer.)
C. D. McDaniel, 2072 East 55th St., Cleveland, Ohio.
G. S. McIntire, 412 N. Fifth St., Apollo, Pa. (Dealer.)
Fred Hoffman, Jr., 1963 Sixty-first St., Brooklyn, N. Y. (Interested especially in transmitters.)
Henry Boehning, 2205 Eighth St., Brooklyn, N. Y. (Wants 30-volt, 5 to 10-ampere D. C. generator or motor generator for radio work.)
Donald McCamman, Lebanon, Ky.
W. B. Dobson, 201 University Ave., Toronto, Ontario, Canada.
Ratcliff & Broyles, Barnes City, Iowa. (Retailers.)
George Fisher, P. O. Box 514, Atlantic City, N. J.
J. W. Irwin, 5754 Holmes Ave., Los Angeles, Calif. (Builds sets.)
New England Stock Co., Box 79, Haverhill, Mass. (Distributors and retailers.)
H. H. Oge, Box 32, Boonville, Ind. (Wants to represent reliable wholesalers.)
N. Appelbaum, 178 Middleton St., Brooklyn, N. Y.
C. H. Barnett, Hagerman, New Mexico. (Builds sets for the public.)
Ralph L. Arthur, 924 South Sixth St., Atchison, Kansas. (Dealer.)
E. E. Gosher, Brandon, Vermont.
Howard E. Litchfield, 14 Shepard St., Lynn, Mass. (Constructs sets.)
Warren T. Slowen, West Haven, Conn.
Wesley McArdell, Radio Construction Club, Brooklyn Technical High School, Manhattan Bridge Plaza, Brooklyn, N. Y.
Samuel O'Toole, 75 Baldwin St., Pawtucket, R. I.

Coming Events

AMERICAN RADIO EXPOSITION, Grand Central Palace, New York City, October 6 to 13, 1923. J. C. Johnson, general manager.

ANNUAL HOME AND CITY BEAUTIFUL EXPOSITION, featuring radio exhibits, Atlantic City, N. J., June 16 to September 8, 1923.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEER, Pacific Coast convention, Del Monte, Cal., Oct. 2-5. F. L. Hutchinson, 33 West 39th St., New York.

He Boosts the Radio Game

MR. O. H. HOVEY, general manager of the Southern Radio Supply Company, Perry, Okla., is a real booster for the radio industry. He seems to take a broad view of the business and does many things easy for any one to do to advance the business in a broad-gauge manner. For instance, his company's stationery is printed in two colors on tinted stock and carries the following good propaganda in red: "Get the market reports. Enjoy splendid concerts and lectures. Get the weather reports. Outfits cost no more than a good phonograph. Give far more pleasure and satisfaction, and no more trouble to operate."

A New Loop Aerial

A LOOP aerial that should prove of interest to amateurs because of its inexpensiveness and convenience is being manufactured by the Ritter Radio Corporation, 232 Canal Street, New York City. The loop is joined with dowels with an upright fitting into a slot at the base. The crosspieces are slotted to take the enameled wire which is sold with the outfit. The loop can be stained to match the color of the particular set for which it is purchased.

Westinghouse Sales Grow

THE Westinghouse Electric & Manufacturing Co., in the three months ended June 30, 1923, booked new contracts valued at $47,649,129, an increase of $15,530,205 over the same period last year. Billings for the same period were valued at $35,094,884 against $25,713,707 last year. In the first quarter of the year bookings were valued at $45,741,000 and billings $39,577,000.

Horne Company Changes

The Horne Electric & Manufacturing Company, whose main office is at Mercer and Colgate streets, Jersey City, N. J., have succeeded the Horne Manufacturing Company and will continue the manufacture and sale of the well-known Horne radio products.

New Radio and Electric Firms

Wayman Electric & Manufacturing Co, Wilmington, Del., $200,000. (Colonial Charters Co.)

Albert Weber, New York City, electrical devices, $50,000; A. Weber, L. Inkeles, M. Kane. (Attorney, L. J. Feinstein, 47 West 34th St.)

United-Edison Electrical Contractors, Brooklyn, N. Y., $5,000; J. Katsch, A. Goldberg, H. Schein. Attorney, R. H. Kittel, 522 5th Av., New York City.

Steel-O-Graph, New York City, make electrical appliances, $250,000; W. C. Lamphier, J. Wood Jr. (Attorney J. S. Twaddel, 261 Broadway.)

New York Central Electric Corp., New York City, has increased its capital from $7,000,000 to $10,000,000.

Rubes Radio Manufacturing Company, Delaware, $125,000; Rep. C. A. Vauhan, 302 Church street, New York City.

Drew Electric Construction Co., Rochester, N. Y., $10,000; G. E. Drew, G. H. Pond, F. B. Warren. (Attorneys Carnahan, Pierce & Block, Rochester.)

Penn Fibro-Electro Co., deal in transmitting and receiving apparatus radios, $500,000; Arthur Johns, Clifford Roberts, John E. Voege, New York, N. Y. (U. S. Corporation Co.)

Home Electric Co., N. J., 300 shares preferred stock, $100 each; $1,000 common, no par value; A. C. Maccabe, 50 Church St., New York City.

Warner Speed Control Corp. of America, New York City, to manufacture motors and engines, 20,000; G. and A. Worsnop, W. G. Lovatt. (Attorney, H. S. Hechheimer, 1540 Broadway.)

International Patents Development Co., Wilmington, Del., engineers and contractors, $1,000,000; Frank H. Hall, Daniel Royse, New York, N. Y.; Arthur R. Oakley, Pearl River, N. Y. (Registrar & Transfer Co.)

Electric Milker Corporation has changed its name to Electric Products Corporation, Chicago, Ill.

Superior Radio Inc., has changed its name to Shipley & Co., Inc., Philadelphia, Pa.

Put Your Shoulder to the Wheel for the Second Annual National Radio Week!

LAST fall the idea of National Radio Week was originated in the editorial columns of RADIO WORLD. The radio press and trade generally took up the matter and everybody worked hard to make this first annual seven-day event of importance.

Another year is swinging around, and it is time now to think of the Second National Annual Radio Week. Every radio editor of a daily paper, publishers of all radio magazines, and manufacturers, distributors and dealers should give careful thought to the Second National Radio Week.

We shall be glad to have special opinions from all those interested. What do you think the date should be, and what are the special features you would suggest for this seven-day period? Last year's National Radio Week came just about the time when folks were making purchases for holiday gifts. Why not fix on about the same period this year?

RADIO WORLD does not claim ownership of the National Radio Week idea. It merely acted as the original sponsor. The event is too big a thing for any one publication to try and keep to itself.

Now, let's all get together, make the right kind of preparations, and see if we can't make the Second Annual National Radio Week bigger, better, and more far-reaching in every way than the initial event of last year. THE EDITOR

Newark, N. J., Considering City Broadcasting

EDITOR, RADIO WORLD: Your favor of the 23d instant came duly to hand requesting an opinion from Mayor F. C. Breidenbach regarding a municipally-owned-and-operated radio-broadcasting station, and was taken up at a meeting of the Board of Commissioners of the City of Newark, held this day.

Hon. William J. Brennan, Director of the Department of Public Safety, moved that your letter be referred to Mayor F. C. Breidenbach. The motion was adopted.

Very truly yours,
W. J. EGAN,
Newark, N. J. City Clerk.

Springfield, Mass., Is Lucky on Broadcasting

EDITOR, RADIO WORLD: Replying to your request of the 23d inst., would say that the Westinghouse company has a large equipment in this city, from which they are glad to broadcast anything the city desires to send.

I should think cities not so favored would need a municipally-owned station—a source of pleasure and profit.

Yours very truly,
EDWIN F. LEONARD,
Springfield, Mass. Mayor.

Baltimore Considering a Broadcasting Station

EDITOR, RADIO WORLD: I acknowledge receipt of your letter of July 23 regarding municipally-owned radio-broadcasting station for Baltimore.

I have had this matter under consideration for some time, but at the moment no definite action has been decided upon.

Yours very truly,
HOWARD W. JACKSON,
Baltimore, Md. Mayor.

Enjoys Us, But Wants a Radio Daily

EDITOR RADIO WORLD: I am a regular subscriber to RADIO WORLD and wish to say that I have enjoyed reading it more than any other radio magazine published. It shows the newest things first and is also full of valuable information. My only regret is that it is a weekly magazine instead of a daily.

Yours truly,
KENT DECKARD.
Rusk, Texas.

Radio Weddings Now in View

APPLICATIONS are coming by every mail from those who wish to participate in the radio wedding which is to be broadcast by WLW of the Crosley Manufacturing Company at the Fall Festival to be held during the last week in August and the first week in September from the Cincinnati Fall Festival. There will be two weddings, one each week, and the whole radio world is invited to be "air guests." A receiving set is all you need to be "present."

Station KFHX Is Correct

IN RADIO WORLD for July 14 the call for KFHX, operated by the Nelson Manufacturing and Supply Company, Hutchinson, Kansas, was published in a list of new broadcasting stations of KFHS. This was incorrect, according to Mr. R. A. Nelson. The correct call is KFHX.

Broadcasting of Fights Helps Demand for Radio Goods

THERE is no longer any doubt that the broadcasting of big fights means a great deal to the radio trade. This was noticeable immediately following the broadcasting of the Firpo-Willard contest. On the day after this event the dealers in New York and throughout the country, particularly in the East, noticed an increase in demand for sets and parts, and the same thing obtained before and after the broadcasting of the Leonard-Tendler bout last week.

The broadcasting of the latter fight, by the way, was handled in masterly fashion. Major J. Andrew White was the man at the microphone. Not only did his voice carry clearly, but Major White made his description so graphic that he delighted millions of fans throughout the country, many of whom have declared that this was the most satisfactory fight broadcasting in the history of radio.

Gimbel's Radio Sale a Wonderful Success

GIMBEL BROTHERS, New York department store, whose purchase of approximately $3,000,000 worth of radio receiving sets from the Radio Corporation of America was announced in last week's issue of RADIO WORLD, have scored what is probably the biggest selling success in the history of the radio industry. The sets were priced at a comparatively very low figure and heavily advertised in the New York daily newspapers. Gimbel Brothers inform RADIO WORLD that over 1,600 sets were disposed of during the first two days of the sale. At the time of going to press sales figures had not been received from the firm's stores in Philadelphia and Milwaukee, which also participated in the event.

Wants Radio Sets for Mail Order Trade

EDITOR, RADIO WORLD: We are contemplating entering the mail order field, and desire to specialize in radio equipment.

Can you furnish us with a list of manufacturers who supply dealers with catalogs for imprint, and also those firms who specialize in small, complete sets at a price which would be low enough to make them specials?

Our activities will be mostly confined to the farmers of foreign birth and we, of course, do not desire to handle trash of any kind, but would want to guarantee all equipment sold by us as far as possible. Very truly yours,

MAHLER'S TRAVEL BUREAU,
By Richard J. Ward.
205 Seventh Ave., New York City.

Likes Our Style—Thanks!

EDITOR RADIO WORLD: As per your subscription offer, I enclose herewith my check for $6.00 in payment for one year's subscription. Your magazine is far-and-away the most interesting and instructive—genuinely helpful—of any now on the market, especially to the thousands and thousands of us who have neither the time nor the desire to become expert radiotricians (or whatever you call 'em), and who nevertheless enjoy our broadcasting-receiving instruments and want to keep in touch with the general progress of radio.

You boil it down for us, give us the essentials, aren't ashamed to use everyday English (some of the publishers foolishly think the way to impress their readers with their superior wisdom and learning is by using extremely technical terms and the terminology of the most expert electrical engineering shopwork), and the questions of your readers do not seem to bore you.

Sincerely,
H. L. SMITHTON.
Cincinnati.

Radio Trade Notes

Modell's has opened another store at Whitehall and Stone streets, New York City, to meet the radio needs of lower Manhattan and residents of Staten Island who use the ferries.

* * *

Freed-Eisemann Radio Corporation, 255 Fourth Avenue, New York City, announce that they have recently added to their organization Mr. A. B. Ayers, formerly with F. D. Andrea, Inc. Mr. Ayers will act in the capacity of Eastern District Sales Manager.

* * *

C. C. Henry, of the Federal Telephone & Telegraph Company, has been appointed a member of the board of directors of the Radio Trade Association of New York City, to fill the unexpired term of C. H. Love, resigned.

* * *

Leading manufacturers to the number of 45 already have signed contracts for space in the second annual American Radio Exposition, to be held in Grand Central Palace, New York City, October 6 to 13.

* * *

Poster & Co., manufacturers of panels, have removed to 244 West 42d Street, New York City.

* * *

The Mercury Radio Products Company, Little Falls, N. J., has been granted the second license issued by E. L. Grimes, of Staten Island, N. Y., for the manufacture of the Grimes inverse reflex, with exclusive rights to the music field, as well as rights with other licensees in the radio field. The Sleeper Radio Corporation, of New York, is at present the only other licensee.

Radio Trade Association to Meet at Radio Show

THE board of directors of the Radio Trade Association, New York City, has accepted the offer of the American Radio Exposition Company to conduct a series of meetings at the Grand Central Palace during the fall exposition of the American Radio Exposition Company which will be held the week of October 6th. The program committee is working on a list of speakers. These general meetings doubtless will be of interest to the entire trade. Exact dates and hours of meetings as well as lists of speakers will be announced later.

WLW Now Used by Salesmen

J. L. WOODS, JR., sales representative of Crosley Manufacturing Company, Cincinnati, has left for the west coast states, but before going he was the center of a re-christening party when he was given a new first initial W in order that he could use WLW as his initials. These stand for the WLW designated by the government as the call letters of the Crosley radio broadcasting station. He now signs his name W. L. Woods, Jr.

Return of the Lightning Rod

HE lightning-rod is coming back, says an editorial writer in the New York World. The first electrical scientists of the time, Thomas A. Edison and Dr. Charles P. Steinmetz of the General Electric Company, have reindorsed it, when properly installed, as a protector of buildings from fires caused by lightning. The National Board of Fire Underwriters now gives a great practical push toward its restoration by declaring that 99 per cent. of such fires can be prevented by a general use of the rod, and by offering its services for the adoption of right methods of installation.

It is a new vindication for Benjamin Franklin and the first lightning-rod, which grew out of his kite experiment some 170 years ago. But it needs to be said that in all this time electrical science has never flatly condemned lightning conductors on buildings and other lofty objects as useless. What killed them in popular favor and use was the "lightning-rod man" and his tricky commercialization of the Franklin discovery. Memories of men now living easily go back to the time when this person was considered a worse pest along the countryside than the book agent or the Yankee-notion peddler. Faulty material, bad insulation, superficial grounding, and failure to follow a direct path from the tip of the rod to the ground, commonly made it useless and often worse.

Against a return in the lightning-rod's comeback of this ignorance and petty swindling, owners of exposed property can have the help of the fire-insurance companies, and with it the incentive of reduced insurance rates. Nor will the run of humankind fail to gather comfort from this assurance of electrical science in its present rapid and extraordinary developments that the dreaded lightning stroke may yet be robbed of its power to injure or destroy where due precaution is taken.

No Good

SAY, Sam, what did yo' all do wif dat radio set you bo't for yo' Melindy?"

"Done gone trow de darn ting fru de winder. Sum smart perfesser told us over it dat chickun oughtn't to be eaten, and prescribed cown beef 'stead. I ain't gonna have no man tellin' me how to reg'late my meinyou."

LATEST BROADCASTING MAP IN COLORS FREE to RADIO WORLD SUBSCRIBERS

The latest radio broadcasting map of the United States and Canada, containing all the new allocations and changes, is offered *free* to subscribers for Radio World who send in their subscriptions within the coming four weeks. This map is printed on fine map paper stock and has just the information you want regarding broadcasting stations throughout the continent, including army and navy stations.

If you are already a subscriber you can get this map by renewing your present subscription now.

Send direct to this office or you may subscribe thru your newsdealer who can send your subscription direct to us.

Use the coupon attached.

RADIO WORLD FREE MAP SUBSCRIPTION BLANK

Radio World,
1493 Broadway, New York.

For the accompanying $3.00 please send me Radio World for six months (26 numbers) beginning with issue dated .....and also, without any expense to me whatsoever, the latest radio map as advertised.

Name .....

Address .....

City and State.....

If you wish two maps, one for yourself and one for a friend, send $5.00 for a yearly subscription and the two maps will be sent to different addresses if you wish.

Telephoning Over High Voltage Lines

By Lloyd Jacquet

EXECUTIVES from large power plants from various sections of the United States, as well as officials of the Consumers' Power Company of Michigan, witnessed the first demonstration of telephoning over power transmission lines over the company's system between Jackson and Battle Creek last week.

The celebration upon the occasion of the opening of the first new high frequency automatic telephone system was in charge of B. E. Morrow and C. W. Tippy, officials of the Consumers' Power Company, and the first to talk over it.

This system has just been installed by engineers of the Westinghouse Electric & Mfg. Company, who developed and designed the installation. Only two sets, located at Jackson and Battle Creek, are completed. Four other similar stations will be installed at various points along the six hundred miles of transmission lines.

The installation on the Consumers' Power Company of Michigan is a long step in advance of anything yet attempted in experiments with "wired wireless."

This system provides for two-way communication, similar to an ordinary telephone line system. While the radio impulses are guided by the high voltage transmission lines along the entire system, in event of breaks in the power lines, communication is not interrupted, as the radio impulses readily jump the gap. In fact, signals can be exchanged even if several miles of transmission lines are down. During lightning storms, which will interrupt ordinary line telephones momentarily, speech can be transmitted without difficulty over the system. This feature of the installation gives it a marked advantage over the conventional wire telephone circuits.

The high frequency apparatus, or the radio units of the system, are located at the various terminal stations. Two antenna wires are strung for a short distance on the towers which support high tension power lines. One of these is a sending antenna and one used exclusively for receiving. The antenna wire is given about 12 feet clearance from the power line wire. The upper or transmitting antenna is connected to the transmitting set and the lower antenna to the receiving set.

High frequency currents are generated by a 250-watt vacuum tube similar to those used in broadcasting stations. This tube operates on 2,000-volt direct current. The high frequency current flows into the transmitting antenna and instead of being broadcast through the air, it induces, by electrostatic and electro-magnetic induction, corresponding high frequency current in the adjacent power line and this high frequency energy, superimposed upon the energy transmitted normally by the power line, is carried on the power line to the receiving station where, by induction, it is led into the receiving set through the receiving antenna. This unit is an ordinary long wave, coupled circuit radio receiver. It is equipped with a detector and one-step amplifier.

The high frequency currents generated by the 250-watt vacuum tube type oscillator and modulated by a second 250-watt vacuum tube to the grid of which the voice frequencies developed by the microphone are applied. A 50-watt vacuum tube is interposed between the relatively weak microphone circuit and the grid of the 250-watt modulator tube for the purpose of amplifying the voice

Station WLW Locates Missing Man

THE value of the radio broadcasting station in its relation to locating missing persons and articles was fully demonstrated when WLW of the Crosley Manufacturing Company, Cincinnati, located Herbert Weber within a day after his description had been sent into the air. This marks the first recovery of a person by radio although thousands of messages and descriptions have been sent to all parts of the world by radio.

Immediately after the church services by radio, WLW broadcast a description of Herbert Weber, a deaf and dumb man whose wife had not been able to locate him. He had wandered off and so the wife turned to the new agency, radio, to help her in her search. She gave a full description of him and then trusted to the modern miracle to do the rest.

T. Paul Jordan of Newtonsville, Ohio, a radio listener to the church services, heard this message of distress and began a search for the missing man. It was not until the next afternoon that the deaf and dumb man was found wandering along a country road. Mr. Jordan approached him and wrote on a paper the message he had heard on his radio receiving set. The man wrote back that he was the missing one. Within a short time he was safely home.

Radio as a Means of Expression and Contact

By Dr. Lee De Forest

TO celebrate its first anniversary WOR has tonight assembled representatives from the three great principles of expression—the newspaper, the motion picture and the radio—and has done me the honor to speak on behalf of radio as a medium of expression. I like better to consider radio broadcasting as a medium of *contact,* for without question it has already demonstrated the fact that radio broadcasting brings the millions of our citizens, high and low, in cities and in the most remote districts, into contact with our leaders in every field of activity—political leaders, leaders of the drama, of art, great editors, captains of industry, singers and musicians—in a manner in which no other medium since the beginning of civilization has begun to approach. And I hold that it is in this peculiar property of personal contact between the widespread millions of our citizens and the comparatively few gathered nightly in the small auditoriums of our broadcasting stations which is more responsible than any other factor for the immense and ever-increasing popularity of radio.

In 1909, when the idea of radio broadcasting first occurred to me, and the music of the Metropolitan opera singers was for the first time launched upon the ether, and again in 1916, when, for the first time, regular radio concerts were maintained, from the old station at Highbridge, when I had a small but intensely interested audience growing in numbers nightly, there began to dawn before me a vision of the astonishing potentialities of the radio broadcast, which vision the last eighteen months has been bringing more and more into reality. But I confess that in those early pioneer days my eager imagination fell far short of picturing the astonishing hold with which this idea so suddenly gripped our entire nation. And not alone the American people, for I have found that, in England, France, Holland, and even in Germany, wherever the fame of American broadcasting has penetrated it has enkindled to an astonishing degree the imagination of classes which one might doubt would respond so quickly. In truth, the broadcasting idea, which America may be justly proud of originating, is already outgrowing national boundaries. Already the radio telephone is beginning its benign work of breaking down the artificial barriers erected by politics or race. Nothing since the early days of the discoverers has so appealed to the imagination of a nation. No other medium in man's history has demonstrated its unique powers for uniting far separated sections of a great country, for causing to become acquainted dwellers in distant districts from north to south, from east to west. More than the newspaper, more than the postal service, this mighty hearing of the spoken voice in greeting, the public address, the sermon, the lecture, the musical program, is actively uniting us in a bond of common fellowship, common acquaintanceship as no other conceivable instrumentality can accomplish. I predict that, as an educational medium, the radio telephone broadcast will in time prove second in importance only to the public school. Already we see a closer interlinkage between the people of Canada and ourselves, due to the broadcasting idea; and soon these benefits will extend to Europe, between the peoples of the Old World, always heretofore strangers; enemies because strangers and personally unacquainted. When, night after night, the citizens of foreign lands will hear the friendly words, the music and the songs from across strange frontiers, then gradually will the feelings of enmity and suspicion, based chiefly on distance and ignorance of each other, change to understanding and good will. Thus I maintain that radio broadcast with its irresistible educational influence is destined to prove one of the most potent powers for the abolition of war.

So rapidly is this movement growing that it will not be long before the necessary high-power broadcasting stations will be planted in all our cities, each covering a sufficiently wide area to enfold the entire land in a mantle of music; to breathe into every ear which cares to listen voices of comfort, of nightly companionship with the world's doings and the world's best minds. "Just a Song at Twilight," but its lovely echoes are being heard in the miner's cabin, in the rancher's hut, in the living room of the old farmhouse, over the mountain range, beyond the desert, across the silent prairie, over the wastes of sea. And who can say what minds are not awakened, what souls that were deadened, what hearts long embittered by loneliness, will not be stirred to a new life, a new outlook by that sound?

When one seriously considers the human side of this broadcasting idea and its possibilities one must admit that it possesses potentialities for universal education and for all the trail of good which results from universal education, which can be compared only to that brought about during the past five centuries by the art of printing. Only this new revolution will grow to maturity in a decade instead of 500 years—a graphic commentary on the acceleration of man's present progress.

I have for a long time maintained that this educational value of radio broadcasting will prove by far its greatest worth to the people of our country, and, later, of all nations. No doubt just now the entertainment feature is the most striking; the phase most appealing to the popular desire, naturally enough. Unquestionably the fine programs which are now being given by the large broadcasting stations are accountable for the astonishing spread of receiving stations during the past eighteen months.

But comparison of radio broadcasting with the introduction of the printing press is not too bold. When newspaper and press syndicates realize its full possibilities in their own field (and their leaders are rapidly coming to this realization) this comparison will become concededly commonplace. Editors now have a medium where antenna wires take the place of Mergenthaler typesetters, ether waves of ink and press paper, head phones of spectacles, and ears of eyes. It is indeed gratifying to me to note the whole-hearted and enthusiastic co-operation of the American press generally with the broadcasting idea. Without this broad vision on the part of newspaper men the present popularity and astonishingly rapid growth of broadcasting would have been quite impossible.

It is therefore a great pleasure for me to speak to you tonight, in company with that Nestor of the American press—Melville E. Stone, of the Associated Press—who, earlier than any other American newspaper man (as far back as 1899), foresaw something of the immense possibilities of wireless in newspaper service, and who has ever since those early years stood out conspicuously as a believer and advocate in the future of wireless as a medium of contact with the people.

Such occasions as this tonight, when I again take part in the radio telephone broadcasting, which I have labored so many years to bring about, are occasions of profound personal satisfaction. They bring back vividly to me the countless nights of step-by-step upbuilding of this idea, and the device which has made it finally a reality. And with them comes a profound sense of gratitude, for I realize on such occasions as this the personal sense of contact and friendship with the untold thousands of listeners who are realizing with me the actuality of an old dream.

Address by Dr. Lee De Forest, broadcast from Station WOR, July 23, 1923, on its first

An Unusual Broadcasting Anomaly

ALTHOUGH the words of President Harding when he spoke in the Civic Auditorium at San Francisco on July 31 were heard as far away as New York and Washington within one-fifteenth of a second after they were spoken, according to telephone engineers, it was nevertheless the following day and month when they were heard in New York. The President began speaking at San Francisco at 8 o'clock, July 31, which was midnight in New York (daylight saving time), and consequently he was not heard there until August 1.

Delights of Radio for the Hard of Hearing

JOHN G. GEBHARD, of Mt. Vernon, N. Y., writes to the New York Times as follows:

There is one feature of radio broadcasting which should get wide publicity. I refer to radio for the deaf. Not all deaf people can use a telephone, but a large majority of them can, and every one of these would find a good radio an unspeakable joy. To those who have good ears, listening-in is more or less of a mere pastime; but for those whose poor ears catch only a fraction of the words and other sounds around them, radio broadcasting becomes a new and delightful entrance into the joys of hearing.

I am 65 years old and hard of hearing, but the happiest hours of my days are those I spend with my home-built radio receiver. One day stands out with unforgetable distinctness. It was one of those hot June days when the mercury was soaring into the nineties. In the middle of the afternoon, as I was touching up a connection here and there, I suddenly heard the strains of the wedding march, and then and there became an intensely interested listener to a wedding ceremony in Newark, N. J., which was being broadcast by WOR. When I had the best of hearing I never heard a marriage ceremony with such distinctness, every word of the officiating clergyman, every word of the responses of the bride and bridegroom, and the bridegroom's kiss were as plain as if the whole affair were taking place five feet away in my own room.

Early that evening my son asked, "Father, who is WGY?" "Schenectady," I shouted, and clapped on my head-piece to hear two magnificent Gregorian chants from a cathedral, broadcast by Schenectady. At 10 o'clock that same night I enjoyed, with my whole family, every word of President Harding's speech at St. Louis on "The World Court," broadcast by WEAF.

The wonder of it all was that each of these three treats was a complete surprise, extras, which did not appear in the printed programs for the day. No retiring of my radio for the summer! I'm in for listening every day in the year, barring thunder weather.

Radio for the deaf is my slogan, which I wish might be sent out broadcast from

IMPORTANT NOTICE

While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

European Radio Dispatches for American Dailies

THE Canadian Department of Marine has issued a license for the erection of a high-powered press radio station at St. Margaret's Bay, Nova Scotia, near Halifax, to C. F. Crandall of the British United Press, acting for the American publishers' committee. For over a year a group of American papers, including New York, Philadelphia, Chicago and other dailies, has been operating an experimental radio station at Dartmouth, across the bay from Halifax, for the reception of wireless press reports from London and Europe, and relaying them by land lines to the newspapers. The project will now be made permanent.

Radio Broadcasting Now Permitted in Germany

A BERLIN dispatch to the Associated Press states that the popularity which wireless broadcasting has attained in the United States has been directly responsible for a decision reached by the Ministry of Posts and Telegraphs to lift the embargo on wireless telephones, beginning Sept. 1. The present prohibition restricts the use of all wireless apparatus to commercial purposes.

Applications for private wireless telephones must be filed with local post offices, which will supply programs and supervise broadcasting in order not to interfere with the official or commercial use of wireless.

THE BOY MECHANIC

700 THINGS FOR BOYS TO DO

480 Pages—700 Articles
800 Illustrations — Cloth

Price $2.00 Prepaid

The Ideal Book for the Wide-Awake Boy

All the things described in this volume have actually been built or experimented with by boys. The ideas contained in "The Boy Mechanic" would more than keep a boy occupied until he grows up and also be an incentive to original thinking and achievement.

The Most Interesting Boys' Book

Unlike so many other books of a somewhat similar nature, it is not confined to only one or a few subjects, but describes 700 different things boys can make and do in the fields of mechanics, electricity, sports, arts and crafts work, magic, etc.

An unusually generous book; size 7 by 10 in. and 1½ in. thick; printed from large, clear type on high grade book paper and durably bound in cloth. Attractive four-color cover design.

Wholesome, Practical, Instructive

Besides telling how to make scores of things useful about the house, full and complete directions are given for constructing hundreds of things which appeal to the heart of every boy.

Many hours of enjoyment are in store for the boy who becomes possessor of this book.

Construction of New Type Transatlantic Receiving Sets
By M. B. SLEEPER
Fully Illustrated. Price 75 Cents

IN addition to the listening to ships and broadcasting stations on short wave lengths there is a peculiar fascination about listening to the high-power telegraph stations of England, France, Germany, Russia and Italy as well as those located in the Pacific Ocean and the Oriental Countries. It is much easier to do this than most people imagine. The sending is very slow, a feature of assistance to the beginner in telegraphy. Several types of receiving sets for this task are described. Detectors, amplifiers, oscillators, etc., for long distance reception are also described. Suggestions for the operation of relays by the signals and the reproduction of them on a phonograph are given. In addition there is some valuable data on home made wavemeters for testing and experimenting.

Tale of Woe

By G. Lorimer Bascom

I WAS sitting
* * *
AT MY radio set
* * *
HEARING ALL the news
* * *
WHEN A thought struck
* * *
ME LIKE a flash
* * *
THAT I could hear
* * *
EVERYTHING LOUDER
* * *
IF I attached that
* * *
NEW BATTERY that I
* * *
HAD just purchased
* * *
THAT MORNING.
* * *
WITHOUT MORE ado
* * *
I DUG it out
* * *
AND FISHING behind
* * *
MY SET I detached
* * *
TWO WIRES that I
* * *
THOUGHT WERE my B
* * *
BATTERY LEADS.
* * *
THEN I turned on
* * *
THE JUICE and
* * *
THE TUBES tried to
* * *
COMPETE IN brightness
* * *
WITH THE 100 watt lamps
* * *
THAT THEY use on the signs.
* * *
BUT JUST for a second
* * *
BECAUSE AFTER THAT they
* * *
JUST WENT out and
* * *
I REALIZED that
* * *
I HAD spent eighteen
* * *
DOLLARS without ever
* * *
GETTING ANYTHING for
* * *
IT AND I was mad
* * *
UNTIL I realized
* * *
THAT I shouldn't
* * *
HAVE TURNED on
* * *
THE TUBES until I
* * *
HAD MADE sure of
* * *
WHAT I was doing.

Wanted Music

LITTLE WILLIE, aged five, was seen standing on the corner intently watching a man with an ear horn strapped to his head. The man was evidently undecided as to what the main attraction was, until Willie went up and asked him why he didn't turn on the loud speaker and let him hear the music.

EXTRAORDINARY SUMMER SUBSCRIPTION OFFER

Radio World and Other Popular Radio Publications for the Price of Subscription for Radio World Alone

Radio World has made arrangements
—by which it is possible
—to offer a year's subscription for
—any one of the following publications
—with one year's subscription for
—Radio World:
—RADIO NEWS or
—POPULAR RADIO or
—WIRELESS AGE or
—RADIO DEALER or
—RADIO (San Francisco)

This is the way to get two publications
—for the price of one:
—Send $6.00 today for Radio World
—for one year (regular price
—for 52 numbers)
—and select any one of the other
—four publications for twelve months—
—This offer good only up to and
—including August 20, 1923.
—Present Radio World subscribers
—can take advantage of this offer by
—extending subscriptions one year NOW.
—Or order thru your newsdealer.

RADIO WORLD'S SPECIAL TWO-FOR-PRICE-OF-ONE SUBSCRIPTION BLANK

RADIO WORLD, 1493 Broadway, New York City.

Enclosed find $6.00, for which send me RADIO WORLD for twelve months (52 numbers), beginning ....., and also, without additional cost, Radio News, or Popular Radio, or Wireless Age, or Radio Dealer, or Radio for twelve months beginning .....

Name .....

Street Address .....

This Offer Good Until Only August 20, 1923

(C. International Newsreel)

This London girl has found a way to listen in in comfort during the hot weather, and was seen floating in the Thames River on an "inner" tube with her wireless set on her lap.

Stockholders in Electric Companies Rapidly Increase

A SURVEY of 156 electric companies made by the New York State Committee on Public Utility Information shows that in nine years the annual sale of shares of stock in the companies, of a value of $100 a share, increased from 92,310 to 1,750,707 shares, and in same period the number of stockholders had jumped from 4,044 to 198,018. An increase in number of shares sold of approximately 1,800 per cent. was sold to a group of investors whose numerical increases was nearly 4,800 per cent.

The point is made that these figures indicate that the customers of the companies are becoming stockholders in them. There are more than 1,600,000 owners of electrical securities in the United States. In 1914 the average number of shares purchased by each new stockholder was 22.8, involving an investment of $2,280. In 1922, when the number of purchasers had grown from 4,044 to 198,018, the individual number of shares bought was 8.6 or an investment of $880.

Station WJY Takes a Vacation

THE call of station WJY, New York City, with one exception will not be heard during its usual program period until some time in September. This station will fill its usual Sunday afternoon hours each week. During the intervening weeks this station and its operating force will be occupied in carrying out certain research work designated to improve the quality of broadcasting from all radio stations.

Radio Station Conducting Tall Corn Contest

ONE of the most unique contests of the year is that being sponsored by Station WOC, at Davenport, Iowa.

This broadcasting station is often heard acclaiming proudly that it is located in Iowa, "The state where the tall corn grows." To exemplify the phrase and to justify the statement in the eyes of any who may be skeptical among its many visitors from other states, a tall glass case has been installed as a part of the station's unique furnishings, and in this case is to be displayed twenty stalks of Iowa's tallest corn.

To stimulate interest in intensive cultivation The Palmer School of Chiropractic has offered fifty dollars in prizes to the Iowa boys and girls who produce the twenty stalks with the greatest average height. Twenty-five dollars is to be paid to the first prize winner, fifteen dollars to the second, and ten dollars to the third.

At the end of the growing season contestants are to submit the average height of their twenty tallest stalks, measured from the ground line to the tip of the tassel. When the winners have been picked they will be notified to ship the corn (crated and with ears attached) to the Davenport station, where the measurements will be checked and the prizes awarded.

Any Iowa boy or girl under twenty years of age is eligible for entrance in the contest.

Capt. Miller Praises Radio for Balloons

IN the recent race four balloons carried radio. Captain Lester T. Miller has written the General Electric Company informally praising the radio set and its valuable use during the race.

"Lieut. Brown and myself during our flight found your set worked very satisfactory in every way," Capt. Miller writes. "As you know the counterpoise we used was a seven-strand copper wire, woven 15 times about our basket. For our aerial we used 300 feet of the same kind of wire. During the night of July 4 and on July 5 we flew at an altitude of about 4,000 feet. All our weather reports were received very clearly; in fact, the clearness of tones surprised both of us as they were clearer than our regular station sets on the ground.

"On July 5, after 8:30 a. m., we flew at a higher altitude and at heights of 5,000 feet and above we found that static was so bad that we were not able to receive satisfactory signals. We consider the set a very fine one and heartily recommend it for purposes of this kind."

Truth in Advertising

OVER $600,000 will be appropriated to further the "truth in advertising" campaign, it was announced at the annual meeting of the Executive Committee of the Advertising Association in Chicago last week. Of this amount $500,000 will be subscribed by forty Better Business Bureaus throughout the country and the rest will be appropriated by the Associated Advertising Clubs of the World.

"The results of advertising depend entirely on the impression that the reading public gets from advertising," said Paul Hunt, manager of the association. "Through the agency of the Associated Advertising Clubs of the World thirty-seven states and a number of municipalities have passed statutes requiring that all advertisements be true representations. We are now trying to get all of the states to pass such laws."

The meeting passed a resolution commending Postmaster General New for his activity and that of his department in helping to identify fraudulent advertisers.

RADIO FANS

Do you want to sell your old set?
Do you want to exchange anything for something?
Do you want to buy something?

If so, why don't you use the Classified Department of Radio World? You can get fine results for five cents a word, minimum ten words. Your message will reach thousands including other fans, dealers, etc., etc.

Try Radio World's Classified Department for your personal radio and other needs.

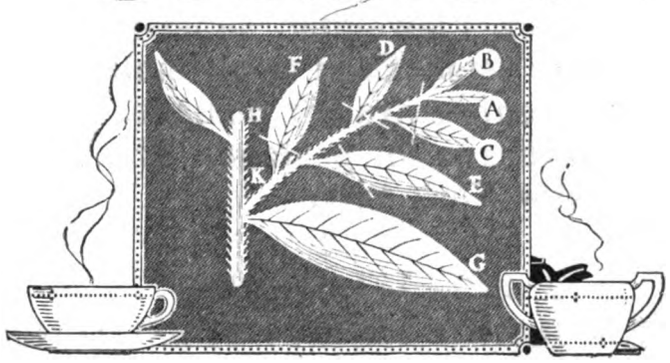
The A.B.C. of Good Tea



THIS diagram shows clearly one reason for the superior flavor, strength and aroma of RIDGWAYS TEA.

The plucking season commences in the early Spring and continues right into the Autumn. At the commencement of the season, the plant sends forth its first tiny shoots. In order to get the very choicest pickings, only those leaves marked "A," "B" and "C" are gathered for Ridgways. These tender, young tip-leaves give to Ridgways Tea that rare quality of flavor which distinguishes the famous Ridgway blends. The leaves marked "D," "E," "F" and "G" are coarser and less flavory and therefore *are never used by Ridgways.*

This carefully guarded Ridgway quality also assures more cups to the pound. When you buy Ridgways Tea you not only get the best tea, but actually more of it than is possible from inferior tea. As an example of rare good tea we suggest that you order Ridgways (GOLD LABEL), the *Genuine* Orange Pekoe.

Be Sure to Insist Upon

Sleeper's Two Latest Radio Books

Two new and remarkably good radio books by M. B. Sleeper —one is entitled "Six Successful Radio Sets," with design data and instructions for receiving sets specially selected for exceptionally long distance reception. The other is "101 Receiving Circuits," being a most complete compilation of diagrams including circuits for a regenerative, superregenerative, Reinartz, Flivver, Flewelling, super-heterodyne, reflex and radio frequency sets. Each book mailed on receipt of fifty cents and ten cents extra for postage. Both books for $1.00 and no extra charge for postage. The Columbia Print. 1493 Broadway, New York City.

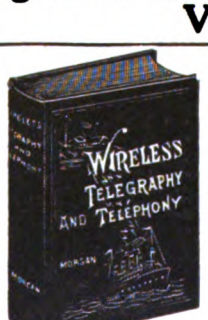
SPECIAL OFFER
TO NEW RADIO WORLD SUBSCRIBERS:

Send $6.00 for yearly subscription for Radio World (52 numbers) and these two Sleeper Radio Books will be sent you free, parcel post prepaid. This offer good only until August 20, 1923. If you are already a subscriber, send $6.00 for a renewal and books will be sent you.

IF YOU ARE INTERESTED IN RADIO YOU NEED THESE BOOKS

Radio Books for Your Vacation

Telling How to Operate a Radio Set—How to Build a Set—Principles of Vacuum Tubes and Other Radio Problems



Wireless Telegraphy and Telephony Simply Explained

By ALFRED P. MORGAN

One of the most complete and comprehensive treatises on the subject ever published. A study of its pages will enable one to master all the details of the wireless transmission of messages. The author explains in simple language the theory and practice of wireless telegraphy and telephony. 154 pages, 156 engravings.....PRICE $1.50

The A B C of Vacuum Tubes Used in Radio Reception

By E. H. LEWIS

Assoc. I. R. E., and Radio Instructor

Written particularly for the person who "knows nothing about radio," but who would like to gain an understanding of the elementary principles of operation of vacuum tubes and various circuits in which they are used for the reception of radio-telegraph signals and radio-telephone music and speech. Illustrated.....PRICE $1.00

Experimental Wireless Stations

By P. E. EDELMAN

Tells how to make apparatus to not only hear all telephoned and telegraphed radio messages, but also how to make simple equipment that works for transmission over reasonable long distances. Then there is a host of new information included. The first and only book to give you all the recent important radio improvements, some of which have never before been published. 392 pages, 167 illustrations.....PRICE $3.00

Federal Audio Frequency Transformer

No. 226
Actual Size

One of the 130 guaranteed Radio Products in the Federal line—all of which are described in our new catalog. Copy sent you free upon request.

Amplification Without Distortion

THIS A. F. Transformer furnishes increased amplification and faithfulness of reproduction of both voice and orchestral music. It will prove a revelation when installed on your present set.

The Federal 226 Transformer has been pronounced by leading Radio engineers, after repeated and exhaustive tests, to excel in all essentials.

It can be successfully used with any vacuum tubes in common use

The same engineering skill, based on twenty-three years' experience in the manufacture of communication apparatus, is behind this Federal Standard Audio Frequency Tranformer No. 226 and the entire Federal line of Guaranteed Radio Products which includes 130 separate units.

Federal Guaranteed Radio Products

Your dealer sells the No. 226 and he can also furnish you from stock or on a quick delivery basis any article made by Federal.

Send for the NEW Federal fully illustrated catalog of Radio Products. You will find it a guide to more satisfactory Radio reception.

A New Electrical Phenomenon and Its Applications in Radio

By Dr. Alfred Gradenwitz

THE discovery of a decidedly new phenomenon by two Danish engineers, Knud Rahbek and Alfred Johnsen, a few years ago came as a surprise to those who, in the well explored realm of electricity, no longer expected any startling novelty to turn up. However, this phenomenon not only aroused

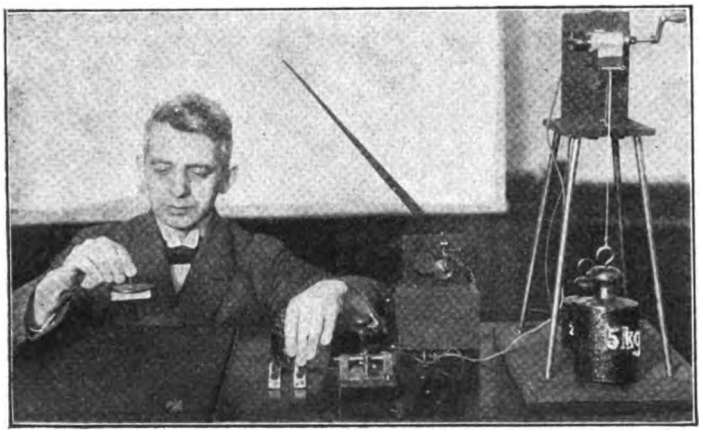

Fig. 1. Fundamental test of a new electrical phenomenon showing a metal plate clinging to a stone slab during the passage of a minute electric current.

the curiosity of those interested in the scientific side of the problem, but soon proved fruitful in remarkable applications to several branches of electrical engineering, most of all to radio telegraphy and telephony. Some of these applications which are the outcome of joint endeavors by the inventors and the Dr. Erich F. Huth Radio Company, of Berlin, are described in the following article.

The new phenomenon may be described as a powerful electrical attraction without any magnetism or iron and bids fair to oust the electro-magnet from its present monopoly in electrical industry. It is best illustrated by the following experiment:

An ordinary lithographic stone slab, 75 grams in weight, coated on one side with tin-foil, is, by means of a thin wire, connected to one of the terminals of an electric circuit, while the other terminal communicates with a brass plate placed on the opposite face of the stone. A feeble direct current is then found to flow through *the stone*, which, strange to say, *firmly clings to the metal plate*, in order immediately to be released, as the circuit is broken. The experimenter's own body can, instead of the wire, be used as conductor, thus illustrating the smallness of the electric current producing such strong effects. The plate may consist of any metal, or even of any non-metallic substance, provided that either this or the stone possesses some trace of electrical conductivity, which it, by the way, may receive by artificial means. An especially striking test consists of demonstrating the mutual attraction of two stone slabs.

In order to understand the above phenomenon, it will be well to remember that the stone slab and metal plate together constitute an electrical condenser. The stone being polished as smooth as possible, their distance in the case of what seems to be actual contact is 1/100 to 1/200 millimeter. Now, as the effect of a condenser, of course, is the stronger as the two armatures come closer together, this system is bound to exert exceptionally strong effects. Moreover, the arrangement opposes to the electric current a truly enormous resistance—in one case as much as 20 million ohms, that is, a figure so high as to make any line resistance appear negligible. It will, therefore, be understood that the current allowed to pass through the system should be quite minimal, in fact of the order of a millionth ampere. This is how a very strong attraction is produced by a current of striking smallness.

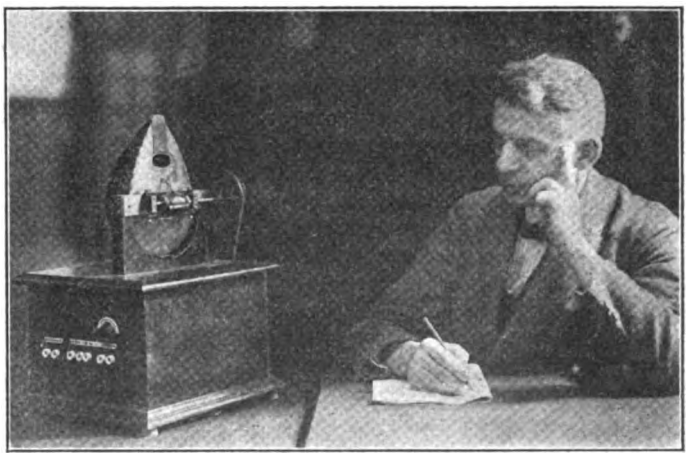

Fig. 2. A mandolin converted into a loud speaker, utilizing the principle illustrated in Fig. 1.

Being present with equal intensity in any metal, and, it seems, in most non-metallic substances, the phenomenon is much more universal than electro-magnetism. Another striking advantage is the well-nigh incredibly small energy consumption, the amount of energy required to lift a given weight being, in the case of the new phenomenon, 300-500 *times less than in connection with an electro-magnet.*

(*Concluded on next page*)

Digitized by Google

(*Concluded from preceding page*)

Even much stronger effects are obtained by using a *stone cylinder* in the place of a slab. One especially striking experiment shows less than 1/10 watt to be expended in retaining a weight of 5 kilograms. This, however, is one three-hundredth part of the electrical energy used up by a standard 25 candle-power incandescent lamp.

Unheard-of vistas are opened up by this new electrical phenomenon. The first application was to the construction of a call relay of unusual sensitiveness,

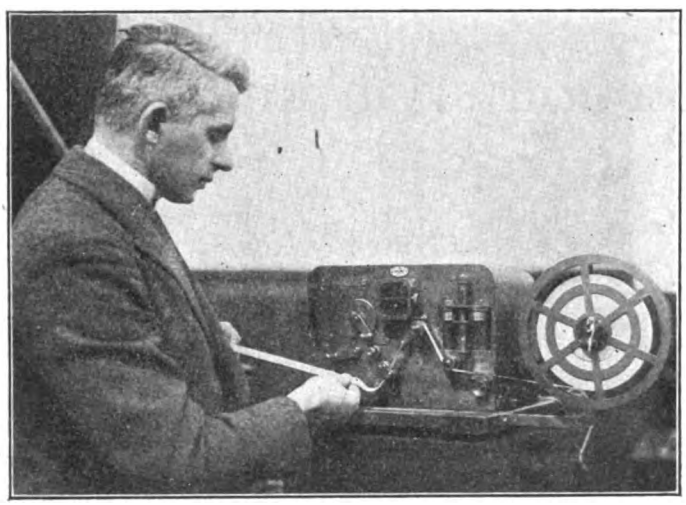

Fig. 3. Huth high-speed telegraph recorder comprising the new relay described in the accompanying article.

actuated by a current of about one millionth of an ampere. Some promising uses of this remarkable relay are enumerated in the following:

RADIO TELEPHONY FROM AND TO RAILWAY TRAINS—Messrs. Huth have on the Berlin-Hamburg railway line developed this system to such a point that any subscriber to the Berlin and Hamburg telephone systems may put himself in connection with travellers in the train, and vice versa. Electrical waves of moderate length, though low energy, generated at one of the terminal stations, are transmitted to the conductor lines serving for ordinary telegraphy and telephony along the railway track. The train carries on the roof of one or more cars a very low antenna in the form of a few wires insulated from and stretched out close to the car roof. This antenna is connected up to a small radio telephone transmitter and receiver of a few watts and is used simultaneously for talking and listening. The traveller, of course, uses an ordinary telephone, such as he is in the habit of employing at home. Inasmuch as the electric currents reaching the train or starting from it are rather weak, a most sensitive relay was required to actuate the call bell or call lamp at both ends and this is where the new relay came in very handy.

HIGH FREQUENCY TELEPHONY AND TELEGRAPHY OVER HIGH TENSION CONDUCTORS—The same system of directed radio ("wired wireless") has lately come into extensive use in connection with power plants, allowing as it does communication to be established at a moment's notice, e. g., between the generating station and its sub-stations in case of breakdown, without resorting to any special telephone line, the electric waves travelling along the high tension conductors. Such apparatus using the new sensitive relays have been installed in a number of great power plants in Germany and Switzerland, while the same possibility of "wired wireless" of course, exists in the case of ordinary telegraph or telephone lines.

NORMAL RADIO TELEGRAPHY AND TELEPHONY—There are many possibilities in store for the new relay even in normal radio telephony and telegraphy, e. g., for calling up ships in the same manner as in the case of wired telephony, so that on small steamers, the services of a permanent telegraphist can be dispensed with. Ships in case of danger can be warned automatically.

HIGH SPEED TELEGRAPH RECORDERS—Apart from the relay using stone slabs and metal plates, the Huth company have developed apparatus comprising cylindrical stones or metal conductors. (In such cases it is generally the stone which has the form of a cylinder.) The first apparatus of this kind is a high speed telegraph apparatus able to record or retransmit Morse signals at enormous speeds, though with extremely small telegraph currents (1/100,000 amp.), the line resistance thus being of no importance. Extraordinarily thin wires (with a corresponding saving of material) can accordingly be adopted and, moreover, the speed of working can be raised to figures so far inaccessible (2000 letters per minute), without any prejudice to the distinctness of type, both in wired and wireless telegraphy.

Another interesting application is to the construction of loud-speaking telephones, where the stone cylinder system actuates a membrane in accordance with fluctuations of the current supplied. It is expected to arrange for a broadcasting service enabling any telephone subscriber at given hours to treat his

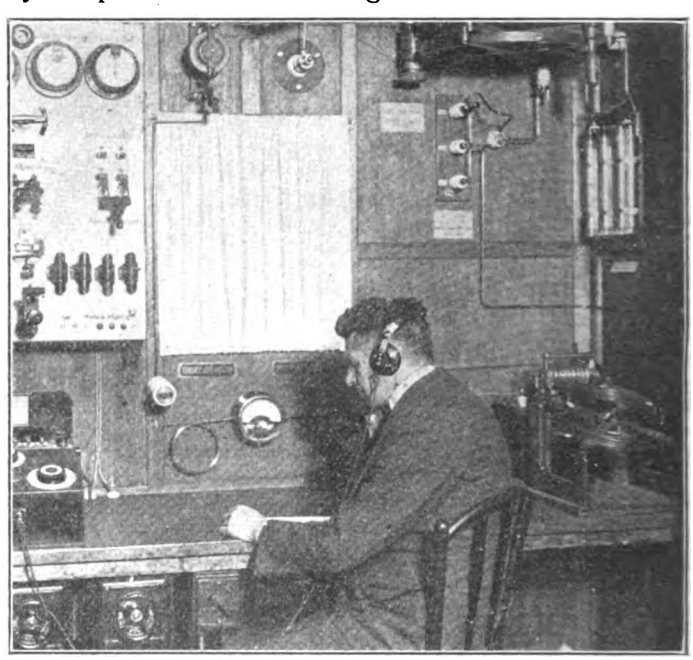

Fig. 4. Ship radio-telephone station designed on the new principle described herewith.

guests either to classical or to dancing music. Wireless transmission of speech and music has recently been effected with a 1 KW transmitter designed on the Huth system between the premises of the firm and places in Sweden, in the Isle of Borkum, in Rotterdam and elsewhere.

There are many other devices based on the use of the new relay, which have already got beyond the experimental stage, e. g., talking films, electrically operated typewriters, and others.

It Doesn't Hurt

IT doesn't hurt anyone to ask for information. They say advice is cheap. It may be cheap, but it is not always sought. If you have some problem that you are not absolutely sure about, it is better to ask questions than to do it wrong.

Making and Using the Buzzer Test

By Thomas Brainard

THERE are many times when we are not quite certain whether our receiving tube is in its most sensitive condition, or when our crystal has its most sensitive adjustment. Especially is this true when there are no stations sending for the moment. Of course, we can guess, but the only way to be really sure is to use some sort of an external exciter, such as a buzzer test outfit. The little arrangement and outfit to be described can be made for a very small sum, and besides performing the function mentioned, may be used for several other useful purposes, such as for testing circuits, exciting a wave meter and so on.

A buzzer test may be easily fitted to sets that have already been built; in most cases without marring the appearance in the least, and with little trouble. Let us take first an ordinary tube set, with a variocoupler mounted near the left hand end of the cabinet. If there are two inches or more between the coil and the wood end, the task will be comparatively easy. The parts that are needed include a flush type push button; a small three-cell flashlight battery; a small high frequency buzzer; and the necessary connecting wire and mounting screws. A strip of brass, about ½-inch wide and four inches long, will be needed for making a bracket to hold the battery in position.

Near the upper left hand corner of the panel, a hole should be drilled for the push button. For the ordinary flush button this should be about a ⅝-inch hole. If you have a drill large enough, you can make this hole yourself, or you may take it to a shop where they do such work. If neither of these methods are convenient, a fairly satisfactory hole may be made by drilling a series of small holes in the form of a ⅝-inch circle, and then smoothing down the ragged edges with a file. Be sure and mark the hole out with a compass, however, and keep the outside rim of the small holes within the line. Two small holes must be drilled for the fastening. These must be tapped, if they do not go all the way through the panel. You can get a small tap for this purpose for about 10 or 15 cents.

The buzzer may be mounted on a small shelf that has been fastened on the back of the panel; or, more easily, mount it on the inside of the wood end piece of the cabinet. This latter is probably the best way, for the buzzer could be kept farther away from the coupler coil. Brass screws should always be used for fastening. Fasten the buzzer at a sufficient height to allow for the mounting of the flashlight battery directly underneath. All of these instruments are kept as near the left hand end of the cabinet, and as far from the coil as possible, so that these metal parts will not appreciably interfere with the oscillating circuits.

Now the brass strip should be bent as shown, and of a shape so that it will fit snugly over the flashlight battery. A hole for a screw should be drilled in each end. After this is done it may be fastened to the cabinet, with the battery in place.

Next the wiring may be done. Most any wire will do. Ordinary bell, or annunciator wire will serve very well. Connect as shown in the circuit diagram. It is best to solder the connections on the battery terminals. The other connections you do not have to be so particular with.

About an eighth of an inch from the top of coupler winding, wind two turns of the bell wire, or some more flexible wire; and anchor it in place with some insulating varnish. This serves as a coupling coil with the coupler winding. Connect one end of this little coil to one of the terminals of the push button; the other terminal of the push button to one of the buzzer terminals; the remaining buzzer terminal to one pole of the battery; and the other pole of the battery should be connected to the free end of the little coil.

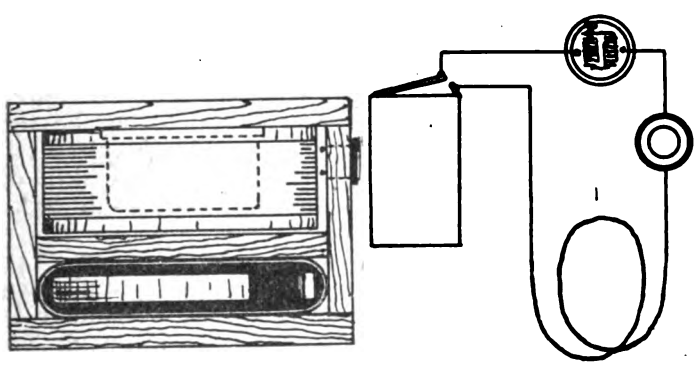

Fig. 1. Construction of a handy buzzer test and circuit diagram of connections used. A single turn of wire around the coupler or tuner is sufficient.

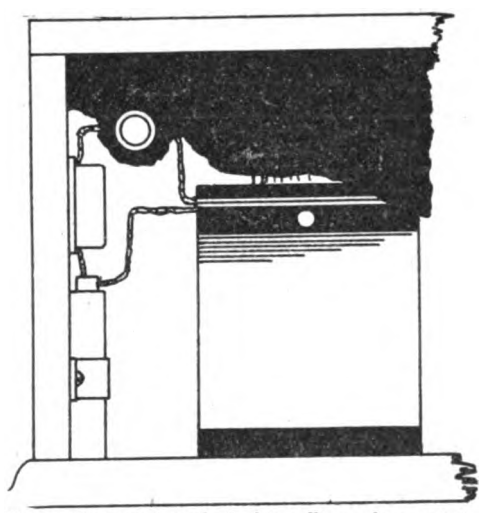

Fig. 2. Suggested method of installing a buzzer test in a cabinet set. This is the preferred method if there is room in the cabinet for the installation.

The buzzer test could be hooked up with a loose coupler set in precisely the same way, except that the little coil would in such a case be vertical; or in other words the coil should be on the same plane as the coupler coil, regardless of whatever position that may be in.

If you do not care to mount the test outfit directly on your set, you may make up a very neat little outfit that may be used whenever and wherever wanted, by mounting the necessary parts in a small box, as shown in one of the drawings. The box should be about 3½ inches deep, 3¼ inches long, and two inches wide—inside measurements. However, the exact size should depend primarily upon the parts which you are able to obtain. The stock for the box, if you intend to make it yourself, could well be ⅜-inch.

Secure a cardboard tube, three inches in diameter and about one inch long, and wind it with about ten turns of No. 22 wire. Then mount the tube in one end of the box, as shown. In the center of this coil, to save

How to Make a Two-Stage Radio-Frequency Amplifying Set for $11.00

By A. E. Herron

WITH the ever-increasing use of radio-frequency amplification for long distance reception a great deal of attention has been paid to this phase of radio engineering by experimenters.

There are several methods in use with various modifications for obtaining radio-frequency amplification depending on the way the tubes are intercoupled.

The tubes may be intercoupled in the most simple and inexpensive way by using tapped coils having both primary and secondary windings. These windings should be tightly coupled and both the primary and secondary should have taps as a means of tuning. This arrangement does not necessitate great operating skill. Each plate circuit can be individually tuned by means of the taps. The efficiency of this type of amplifying set is very high because as each plate circuit is made resonant to the incoming wave a maximum signal strength will be obtained at the output.

The important point in the design of the set is the construction of the tapped coils. The size of the forms

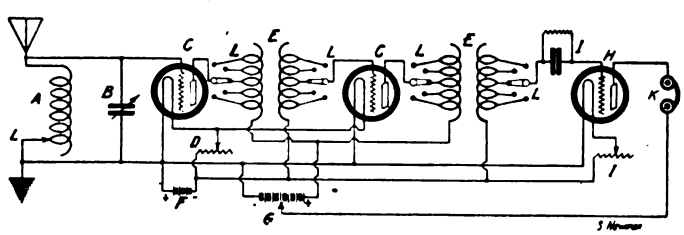

Fig. 1. Circuit diagram of the two-stage radio-frequency set with detector. A—Tuner. B—11 plate variable condenser. C—Amplifying tubes. D—Amplifying circuit rheostats. E—Specially constructed radio-frequency amplifying coils. F—A Battery. G—B battery. H—Detector tube. I—Grid leak and condenser. J—Detector rheostat. K—Phones. L—Switch arms for varying inductance of radio-frequency coils.

is the same for both coils, that is for the first and the second stage. These forms are 4″ in diameter by 2½″ long. The winding should be commenced at one end of the form. When 10 turns have been wound a tap is taken off, but instead of the tap being brought out on top of the form, a hole is drilled through at the point where the tap is taken off and the tap brought out from the inside of the form or tube. The reason for this is the taps will not have to be brought out through the secondary winding, thereby preventing a short circuit between the primary and secondary windings.

The winding is continued and taps taken off every five turns, instead of 10, until 50 turns have been wound. Over this a layer of waxed paper is wrapped before the secondary winding is started. When the waxed paper has been neatly put on and trimmed the secondary coil is started over the primary. It should be wound in the same direction as the primary and taps taken off as before, only these are brought out on the top or outside of the coil instead of inside. Both the coils for the first and second stage of amplification are made the same size and wound in the same manner and the same number of taps is brought out.

The wire for this purpose should preferably be Litzendraght, but if this is not obtainable No. 24 or 26 double cotton covered wire may be used and good results will be obtained. When both coils are neatly wound they should be shellaced and baked until they are dry. Care should be taken when drying or baking them as they are liable to burn if placed in too hot an oven. The form or tube should be of bakelite or condensite, or any other good insulation. Fibre or cardboard tubing should not be used on account of the poor insulating qualities of both. For mounting these coils two holes near the edges should be drilled. These should be large enough for an eight-thirty-second screw to go through. These coils should be mounted at right angles to each other and should not be too close as they are liable to interfere with the circuit if mounted too close to each other. No great skill or experience is needed to make these coils—no more than in making a tuning coil.

The aerial tuning part of the set consists of a specially wound tuning coil and a variable condenser. The tuning coil may be made in the same manner as any other coil or the primary of a variocoupler for instance. Taps are brought out every fifth turn. Fifty turns will complete the winding. When it is completed it should also be shellaced and baked in an oven until thoroughly dry.

The next step is the construction of the grid condenser which is the most important part of any tube set and yet the most frequently neglected. The condenser consists of two sheets of tinfoil ¾″x1″, a sheet of waxed paper 1¼″x4″, two pieces of copper strip or copper foil ⅛″ or ¼″ wide by 2″ long, two pieces of sheet bakelite or condensite ⅛″x½″x2″, two 8-32 screws with nuts and washers. To assemble the parts first bend and fold the waxed paper about one inch from the end, insert the tinfoil between the folded sheets and place the copper strip next to the tinfoil. Let the end of the copper strip with the hole in protrude about a half-inch beyond the waxed paper at one end. Bend and fold the waxed paper once more in the same way, place the second sheet of tinfoil and copper strip as before. Let the copper strip stick out the same distance but at the opposite end from the first one. Fold the paper again over the tinfoil and around until all the paper is wrapped around the whole

(*Concluded on next page*)

(*Concluded from preceding page*)

space, may be mounted the buzzer. A partition is made down the center of the box—or, rather, a little to one side—so that the battery will just fit in snugly; or else a clamp as before described may be used. The wiring is exactly the same as with the other outfit. It will be noticed that the push button is mounted on one side of the box. A cover for the apparatus is not shown, but should be used to protect the interior from dust and dirt.

By including a set of two binding posts in the circuit—ordinarily short-circuited—the outfit may be used for testing circuits, coils, condensers, etc.

To use this box affair, it should be so placed in relationship to the primary coil of your set, that its own coil is in the same plane. Then, when the button is pressed, current will be induced in the primary coil, and from there into the secondary; and by using these high frequency buzzers instead of the uncertain incoming radio waves, the detector may be adjusted without any trouble.

(*Concluded from preceding page*)

thing. The copper strip should have a hole drilled at one end to take an 8-32 screw. Drill a hole at each end of the bakelite pieces about 1½" apart, place the condenser carefully between the two pieces of bakelite and bend the two flaps of the copper strip at either end until the holes in the strips are right over the holes in the bakelite pieces. It may be necessary to pull the strips out a little. Insert the screws and put washers and nuts in place and the condenser is made ready for mounting in the set.

The necessary parts for making this set, with average prices, are as follows:

¾ lb. No. 24 or 26 D. C. C. magnet wire	$1.00
2 2½" long, 4" in diameter tubes, bakelite	.50
1 3" long, 4" in diameter tube for tuning coil	.25
3 standard valve sockets	1.05
2 rheostats	1.50
1 panel, 10"x7"x⅛, bakelite	1.40
5 switch arms and knobs	1.25
1 eleven-plate variable condenser	1.15
51 switch points	1.02
10 switch stops	.40
2 brackets	.25
9 binding posts	.45
Miscellaneous (connecting wire, screws and nuts)	.72
Total cost	$11.00

WD-11 tubes may be used, but this will necessitate the buying of adapters. WD-12 tubes should be used as these are made for the standard socket.

If WD-11 tubes are already on hand, instead of buying the standard sockets WD-11 tube sockets should be bought. This set has been tried out only with UV-201 and UV-201A tubes for the radio-frequency amplification and UV-200 for the detector, but WD-11 or WD-12 tubes should give good results. A potentiometer is not really necessary but slightly finer adjustment will be obtained by its use. The grid leak is made by drawing a pencil line between the two screws on the grid condenser. This line may have to be varied with different makes of tubes, but this is an easy matter, erasing the line or by making it heavier with a pencil. The parts may either be mounted on a piece of board or in a more elaborate affair, consisting of a panel and cabinet. Before the parts are mounted on the panel the panel should be all laid out and drilled.

Every part should be securely fastened to the panel so there will be no fear of any of the parts getting loose when operating the set. It is essential to bear in mind the necessity of keeping the leads running to the plates and grids of each tube as short as possible. Precaution should be taken in placing the parts and in making other wiring connections as short as possible so that the wires are kept as far apart from each other as can be. A short wave amplifying set is very critical and unless these precautions are taken it will be impossible to get results such as could be got had the set been properly wired. Short wave amplifying sets usually depend more for their successful operation on the care taken in building the set than in the use of good parts incorrectly assembled and wired. There is comparatively little difference in the efficiency between this set and a transformer coupled radio-frequency receiver.

The tools necessary for the construction of this set are as follows: screw driver, brace with the necessary drills, a pair of compasses or dividers, and a soldering set. All connections should be well scraped and cleaned before soldering. If soldering paste is used it should be well wiped off from all connections after finishing soldering. Spaghetti tubing should be used on all wires where they cross each other or those that are liable to touch each other if the set is accidently given a jar. There are two wires in each tap leading from both the radio-frequency coils and the tuning coil. These two wires should be securely soldered together and to the switch point, because if they are not, an open circuit in the coil will be the result.

This set is very easily tuned. When first tuning, the switch arms should be left on the fiftieth turn or in other words at maximum on the radio-frequency coils on both primary and secondary. When this is done the aerial circuit should be tuned by means of the tuning coil and the variable condenser which is connected in shunt with it. If signals are not heard the adjustments on the radio-frequency coils should be changed and the aerial circuit tuned all over again as before. The tuning should be first tried out on a nearby station; this will give one an idea roughly just what adjustments are necessary for the broadcasting wave lengths. Care should be taken when tuning this set as it is rather sharp, and if the dial on the variable condenser is rotated too rapidly it might mean the missing of the more distant stations. This radio-frequency set gave excellent results with an outside aerial, but good results should be obtained by using this set with a loop aerial, provided at least two stages of audio-frequency amplification are used.

Audio-frequency has not been tried out with this set, but one stage should be sufficient if telephones alone are expected to be used and the set connected to an outside aerial. A 90 volt "B" battery as the plate potential was found to be sufficient. Of course, as much as 135 volts could be used.

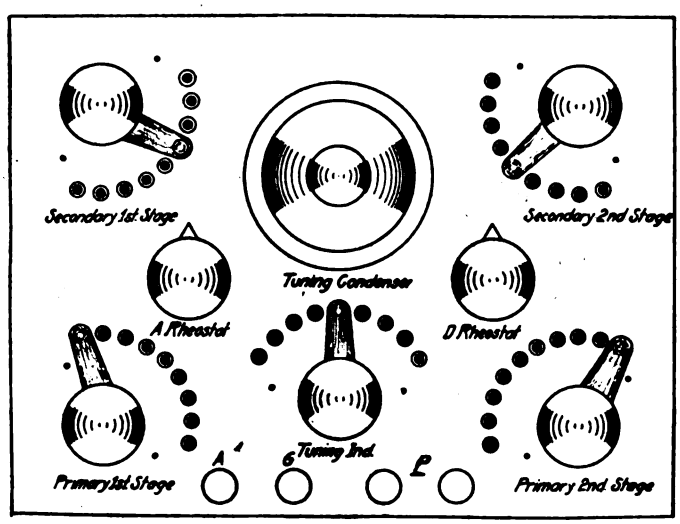

Fig. 2. Suggested panel layout for the receiver described. The antenna, ground and phone posts are located on the front of the cabinet, but for convenience the A and B battery posts are on the rear of the cabinet.

In my experience with radio I have found that this is the least expensive two-stage radio-frequency outfit that can be built and yet give results almost equal to any high priced outfit. If the set is laid out as shown in the diagram, and mounted in a cabinet, it will look as good as any factory made set. The panel could be sandpapered and given a dull finish. This will help to show the knobs and dial much better and give a more pleasing effect to the eye.

Four binding posts are mounted on the outside of the panel. These are: aerial, ground, and two for the telephones. The battery binding posts are mounted on the back of the set on a piece of bakelite or condensite ⅛"x¾"x6". These should be marked so that there will be no danger of connecting the "B" battery in place of the "A" battery and burning out the filaments of the vacuum tubes. Any one building this type of set can be assured that he will own a set worth having for both appearance and results.

How to Read "Radio World" Profitably

By Stephen L. Coles

IT is generally admitted that there is considerable science and a great deal of hard work involved in editing and publishing a weekly journal of any kind. When a weekly requires the important added elements of technical accuracy and a sincere desire to represent broadly the industry with which it is affiliated, other burdens are added. Many years are usually required to so perfect men in this kind of work that they may be competent properly to fill their jobs.

In the course of performing their tasks day by day and week by week it is only to be expected that the editorial staff of a weekly such as RADIO WORLD should acquire an accurate, intimate knowledge of the industry it represents. This may come in various forms; such, for instance, as voluminous correspondence relating to every possible phase of the radio industry. The questions answered in print are but a fraction of the questions asked. Some of these are answered by telephone, some by mail, and others are referred to college professors, engineers, manufacturers or specialists in the line regarding which the inquiry is made. Then, too, it would surprise the average reader to know how much information is derived from the advertising copy received in the business department. The editors frequently are asked to pass upon statements made by advertisers.

The editorial offices of RADIO WORLD seem to be a natural focal point at which gather the many and varied lines of information, to be again reflected to the world by the editorial staff.

To take up only one instance, reference is made to a column which has been appearing in RADIO WORLD for a number of weeks. "Radio Literature Wanted" is its title, and it contains simply names and addresses of people from all over the world. Yet back of these names is an important human interest story which possesses at the same time many elements of great practical business value. These names come to RADIO WORLD through the mail and are sent voluntarily by the people themselves. All of them have a sincere desire to gain information of one kind or another—or they would not take the trouble to write. Every one of them is a potential and quite probable buyer of radio goods. Some of them are only boys, but any wise merchant will tell you that if he can secure the trade of boys and serve them satisfactorily he will build up a business which will last during their entire lives.

This is well exemplified in the hobby of collecting postage stamps. Nearly every one of the prominent philatelists of today began collecting postage stamps as a boy. Many fortunes have been made by dealers in stamps and their business even now is particularly with the younger generation.

The attractions of radio for the young boy have never been exceeded by any form of constructive enjoyment in the history of time. Most of the inventors of radio devices and nearly all the high-class operators began as boys. Here is a field pregnant with immense possibilities for the manufacturer who will carefully and intelligently cultivate it.

That the manufacturer, dealer and distributor of radio supplies is not getting the most possible, nor half of it, out of this wonderfully fallow field has been amply demonstrated to RADIO WORLD through this little column of names. At various times and frequently the names of members of its staff have been inserted in this column so as to find out just how the people to whom these names should be most valuable were responding. The sum and substance of a two months' test is that full advantage of this opportunity is not being utilized. The particular fault seems to be that business men in the radio industry are not properly equipped with printed matter, catalogs and price lists with which to respond to these requests. Many of them have nothing of the kind and send in response to requests handwritten postal cards, typewritten postal cards, badly mimeographed sheets and poorly printed, out-of-date leaflets. One of the largest manufacturers in the industry responded to a request for literature with an envelope which contained nothing when it was received. Of course, this instance probably was a clerical error, but the effect on the recipient was just as unfortunate as if the episode had been clearly thought out and an insult intended.

Advertising, of course, is the basis for success in any business that manufactures reliable goods at a fair price. Advertising obviously includes printed matter with which to respond to requests for information. It would be well for radio business men to call in outside help and provide themselves with printed material of a kind and character that properly will back up their publicity of various sorts and eventually bring business.

Readers should learn to read and benefit by the publications for which they spend money. Every radio business man should, either himself or have someone for him, carefully read RADIO WORLD each week with the sole purpose in view of taking prompt advantage for himself of the wealth of information it contains—a large part of which can be turned into dollars and cents.

Radio in a Cigar Box

(C. Photonews)

Felian Garzia and his cigar box Flewelling receiver. This set has both A and B batteries, vacuum tube, and four head phones, so arranged that four people may comfortably listen in. The entire set is contained in a regulation cigar box, and weighs less than five pounds. Tuning is accomplished by the use of the rubber end of a lead pencil against the condenser plates.

RADIO PRIMER

By Lynn Brooks

WHAT TO BUY—Many times when a particular article attracts the notice of a fan who is constructively bent, he puzzles and frowns when it comes to the act of buying the goods.

He will complain about the fact that the writer does not specify any particular make of material. He knows that there are fifteen or twenty audio-frequency transformers on the market as well as hundreds of makes of other apparatus. What can he do? What does he do? One of two things. He either lets his pocketbook dictate the apparatus, or else he writes a long letter to the author or the editor and asks a lot of questions.

Take your dealer into your confidence and if he is a good business man he will recommend a particular type of apparatus that he thinks is good. How does he know? Well, he is selling them and he knows what sells well and that is what he is going to give you.

Never let your pocketbook dictate apparatus. If you cannot afford the very best, wait a week or two until you can. You can never gain anything by scrimping. In radio just as in anything else the article is worth just what you pay for it. Sometimes it is worth considerably less, and this is generally the case with cheap apparatus. You pay less and you get considerably less than you paid.

Because it is cheap in price does not signify that it is good in quality, even though you may run across a bargain every once in a great while.

WHAT CIRCUIT TO USE—When it comes right down to the final analysis it is a pretty tough job for the uninitiated to pick the best circuit to work with. There are so many that crop up every day, every week, every month, each claiming its advantages over all the predecessors, that it is a tough problem to choose among them.

One of the greatest mistakes that an amateur can make is to tackle the more intricate circuits. There is always some little detail that he will not understand and cannot figure out.

Roughly, we can classify tube circuits into two classes: The single circuit receivers and the double circuit receivers. They each have their advantages and their disadvantages, and their relative capabilities and incapabilities.

The single circuit receivers are simple to construct and tune. They have great volume and fairly sharp tuning. Most of them can be easily constructed from few parts in a couple of hours' time, if care is taken. They are simple to work, as they generally have but one or two controls.

Their disadvantage is that if they are of the regenerative type they will re-radiate, due to their being powerful oscillators. This will cause a great amount of disturbance to neighboring sets if they are not handled correctly. They cannot tune out interference as well as the double circuit sets, and for that reason it is more than likely that distance work when a local station is on will be impossible. Their salvation, however, lies in the enormous volume of which they are capable.

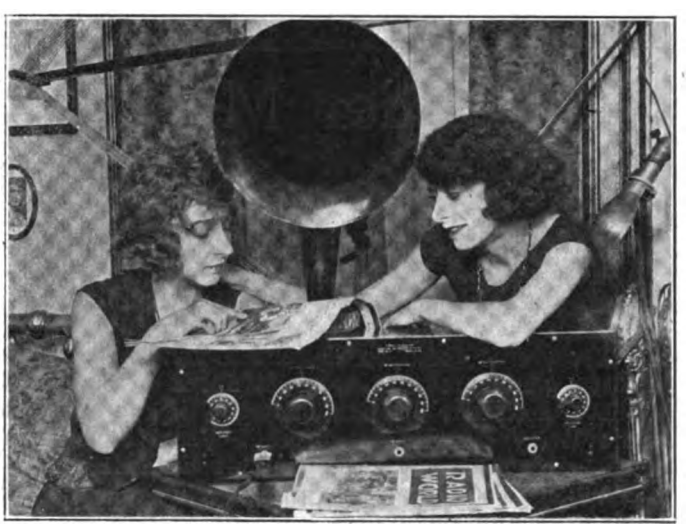
The double circuit sets are far more intricate of construction and the controls are tripled in most cases, as besides the coupling and other controls there is generally a primary inductance control. However, their selectivity is far greater than the single circuit, and finer tuning is possible, eliminating to a great extent the interference noticed in single circuit sets. The range of a double circuit set compared with a single circuit set is about even, as both are capable of doing excellent work, the only drawback being that it takes more care and experience in the construction and operation of the double circuits than the single circuits, and therefore the beginner most always goes to the simpler sets.

Any circuit, whether crystal or six tube regenerator, requires care both in operation and construction if good results are to be expected.

The Radio Woman

I HAVE received the following interesting letter which I am glad to publish in the hope that it will inspire others:

"In RADIO WORLD for July 14, 1923, you published our photograph under the heading, 'Winners of non-stop radio golf contest,' but neglected to publish our names with it. We feel highly honored in having our picture published in RADIO WORLD and we are requesting that you publish our names in another issue, using the photo attached herewith or in any way you see fit. You know, Mr. Editor, that it is no 'cinch' to cover



Winners of the recent six-day non-stop radio golf contest and enthusiastic readers of RADIO WORLD. On the left, Miss Violet Vee, and on the right Miss Valerie Vee, both of New York City.

132,000 miles by radio and we are somewhat proud of our record and challenge anyone to beat us.

"It might be interesting to state here that we have been radio fans for some time (our first set being a simple crystal set), and also that we have been readers of RADIO WORLD from almost the first issue. We congratulate you for turning out such a splendid radio publication and thank you for publishing our picture. —Valerie Vee, Violet Vee."

Safety First With Tubes

DO you realize that for a few extra pennies you can safeguard your tubes and prevent them from blowing out? It is very easy. All that is necessary is two of the small flat fuses such as are used by the telephone company to safeguard the transformers. They only cost a few pennies apiece, and will stand watch over your tubes, and you do not have to worry when you are away for fear that someone will unknowingly blow your tubes and cost you money to get the set working again.

Receivers Recommended for North Pole Messages

HARTFORD, CONN.—With the coming of each radio season, particularly in the early fall, the radio amateur prepares for greater distance in receiving and transmission and those who were content last year to tune in distant broadcast stations are now preparing their equipment and lifting their antenna another notch or two for the purpose of listening in for Wireless North Pole, Donald MacMillan's radio in the Arctic.

This new extension of the amateur's prospective range, along with the novelty of hearing code dispatches from the polar exploration party, has prompted many amateurs to ask what receiving equipment is best for reception of messages from WNP.

Basing his opinion on the inspection of a large number of reports and experiments by amateurs who are putting much time and money on this very problem, Howard F. Mason, department editor of "QST," published by the American Radio Relay League, which furnished a radio operator for the Arctic ship, advises listeners to install either a regenerative receiver with one stage of audio amplification or a superheterodyne with tuned radio amplification using the "neutrodyne principle" in the amplifier.

"As WNP is sending on amateur waves, the receivers that have been adopted by the majority of A. R. R. L. relay stations will be the most practical to use in picking up messages from the Pole," Mr. Mason believes. "The regenerative set with one stage audio is still popular. It is being improved over the older models by using coils and condensers especially designed to minimize losses.

"The superheterodyne, which has been always the ultimate in a receiver for short waves, has been reduced to a more practical basis this season than last, owing to the advent of the 'neutralizing' feature, by Professor Hazeltine, and by the new type of tubes recently placed on the market. These consume small amounts of filament current and do away with the necessity of having a large storage battery."

Weather Maps Aid Amateurs to Foretell Radio Reception

MINNEAPOLIS, MINN.—Radio fans may have to add a barometer to their equipment and study maps issued by the weather bureau to determine their range of transmission or reception if the theory that radio waves tend to follow isobars, or lines of equal pressure area, advanced by Donald C. Wallace, assistant division manager of the American Radio Relay League, is correct. From experiments made at his amateur station in this city, Mr. Wallace is convinced that radio reception may be foretold with a fair degree of reliability.

The subject is comparatively new and the most that can be said for it is that it makes a start at explaining why reception is poor at certain times and why stations at various points of the compass are heard with changing strength regardless of their actual distance. "If a daily weather map is used," says Mr. Wallace, "it will be found that not only do waves tend to follow the lines of equal pressure, but the range of one's set can be determined some hours in advance.

"Recently a striking example of the effect of these high and low pressure areas occurred. A tornado passed through Louisiana making a low pressure area, while in the northern part of the country there were no disturbances and a high pressure area existed. Radio fans heard nothing more than 100 miles distant.

"Sometimes signals take a round-about course and follow the isobars, and in this case, marked fading exists. This is due to the fluctuation at the edge of the high pressure area that exists in between. On some nights the whole country has the same barometric pressure, and on those nights, stations from all sides come in. The Mississippi Valley often has the same barometric pressure; thus signals north and south are apt to be consistently loud while they vary east and west where barometric differences are greater."

Let Strange Wires Alone!

A LETTER has reached RADIO WORLD from the engineer of a western power and lighting plant, telling how a young radio enthusiast was nearly killed. It is designed as a warning to all well-meaning young men who see an opportunity of using a wire for an antenna, without first considering just what that wire is.

This young follower of radio was prevented from erecting an antenna because of the fact that the neighbors on both sides of his house objected to his stringing the wire on their property. As there was an electric light pole outside his house, and about 20 feet from his bedroom window, he climbed the pole, insulated wire in hand, and attached the wire to the incoming side of the transformer, or the side that delivers 110 volts. As the wood was dry and he was wearing rubber soled shoes, nothing happened. He threw his wire across the lawn, and later attached it to a string, preparatory to hauling it in his window. As he pulled the wire it crossed the high tension side of the transformer. He had just touched the wire when there was a flash, and that whole section of the town went dark. He went to the hospital, badly burned, and crippled on his right side for life, but lucky to be alive. The supply was 20,000 volts—enough to kill him instantly had he made good contact.

This should be a warning to many fans who are tempted to string their antenna across the nearest light pole, or attach it to some handy and convenient wire that is already strung up. Don't do it!

Washington Now Has Two Powerful Broadcasting Stations

By Carl H. Butman

WASHINGTON, D. C.—Radio fans in the Nation's Capital are agog with interest in the two new Class B broadcasting stations, WCAP and WRC. Enthusiasts, even several hundred miles from Washington, are beginning to listen in to the high class entertainment from a new radio center. It has been an army and naval radio center for some time but good, private broadcasting has been scarce.

Recently WCAP, of the Chesapeake and Potomac Telephone Company, went on the air, broadcasting a duplicate of WEAF's program in New York. The telephone company's first strictly local effort was the broadcasting of the U. S. Marine Band, which brought in many enthusiastic returns. WCAP was included in the six stations which were to have broadcast President Harding's speech at San Francisco on July 31, connection to be made by telephone wires from the Pacific Coast to their transmitters. Within a month, it is understood, WCAP will be sending a regular program, dividing the time with WRC on 469 meters.

On August 1, WRC, the new station of the Radio Corporation, named the "Voice of the Capital," was christened at 8:00 p. m. Its regular programs will be broadcast Tuesday, Thursday, Saturday and Sunday afternoons, and Monday, Wednesday and Friday evenings, the telephone company's station WCAP broadcasting the alternate evenings and afternoons.

Col. Theodore Roosevelt, Assistant Secretary of the Navy, made a speech at the dedication of the new Radio Corporation's station on Wednesday last. Major Gen. John L. Hines, Deputy Chief of Staff, U. S. A., spoke for the army, while Acting Secretary of Commerce S. B. Davis talked on commercial and public interest in radio.

The opening ceremonies of WRC included a radio message from General Harboard, president of the corporation, who is abroad; talks by David Sarnoff, general manager, and Dr. Alfred Goldsmith, in charge of radio research.

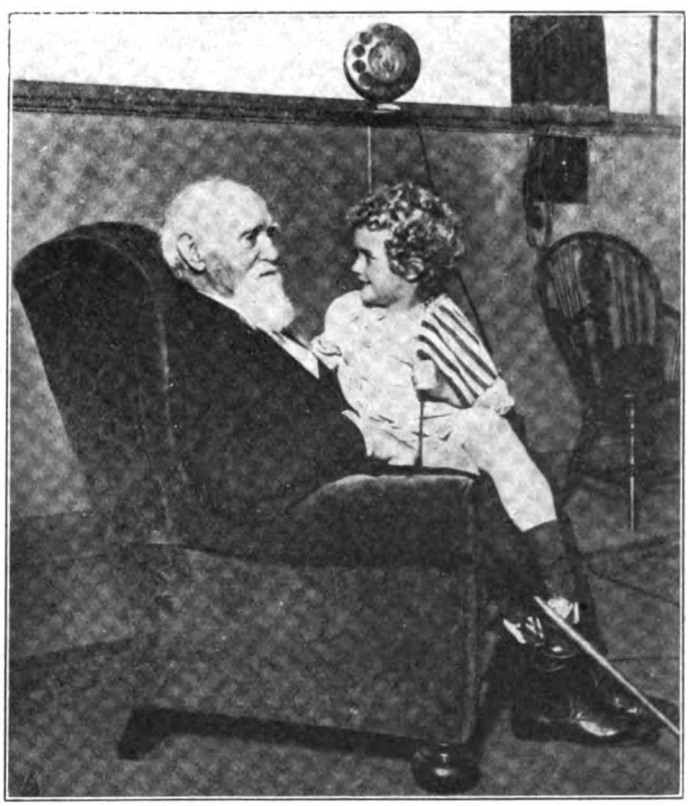
The initial program arranged by Mr. Ralph Edmunds of WRC, was not to be entirely devoted to talks, however, as special musical numbers were broadcast by the U. S. Marine Band, Taylor Bronson leading. Celebrated artists on the program, including Charles C. Tittman, bass soloist; Elias Breeskin, Russian violinist; Ruth Peter, soprano; Victor Golibart, tenor, and Clelia Fioravanti, mezzo-soprano.

WRC has been described technically already; it is a duplicate of the corporation's stations in New York and is rated at 500 watts. Having two sets of apparatus, however, it could in an emergency put out 1000 watts and reach every corner of the continent. Every precaution is taken to insure excellent broadcasting, from the especially sound and echo-proof station, where the artists perform, to the small receiving set on which the operator listens in to his own station and for distress calls from ships with which the broadcasting might interfere.

The new station is under the personal direction of Mr. S. P. Guthrie, superintendent of the Washington District. Mr. W. L. Tesch is local engineer, assisted by Operators Oliver and Rundquist. Mr. Ralph Edmunds is program manager, and is assisted by Announcers Gannon and Berkeley. On opening night Announcer Cross, of WJZ, also assisted. A special feature of the regular WRC program will be a daily "children's hour" from six to 6:20 broadcast by Mrs. Edward Albion who is experienced in child entertainment. She will write all her talks and handle them in a little more personal manner than most broadcasters in an effort to effect a closer relationship with her young audience.

On Monday, August 6, WRC staged a Marine Corps night, at which Brig. Gen. Logan Feland, Marine Corps, spoke and the Marine Band played.

Centenarian and Child Prodigy Make Radio Address



(C. Pacific & Atlantic Photos)

Former Senator Cornelius Cole, 100 years of age, and tiny Richard Headrick, violin prodigy and film star, combined forces in one of the most unusual programs yet broadcast from a radio station when they appeared jointly in a patriotic speech at Station KHJ, the Los Angeles "Times." The two extremes of human age thus combined in one made a striking picture, as well as a most unusual address.

Do You Know?

MANY owners of sets just know that they have to twist the dials and turn on the rheostat in order to receive signals. They do not understand why. Do you realize how much more fun it would be if you had a working knowledge of why a certain thing had to be done? A few dollars invested in good text books on the subject would make the art of tuning and working a set all the more interesting because you would then understand what you are doing.

Station WRC Is On The Air

By J. L. Bernard
Radio Corporation of America

THE new giant broadcasting station WRC, located on the New Riggs Bank Building at 14th street and Park road, Washington, D. C., began a regular broadcasting service on Wednesday evening, August 1. The Radio Corporation of America owns and will operate the new station.

Located in the Mount Pleasant District, one of the highest points in the city, where the antenna wires are suspended 150 feet above the street level, the waves radiating from the station have an unobstructed path in all directions. With the antenna system energized by a powerful 500 watt transmitting set, radio reception from the station in Delaware, Maryland, Virginia, West Virginia, Eastern Pennsylvania and Southern New Jersey should be particularly good, while in the District of Columbia strong signals will be received at all times during the day and evening when the station is on the air. Radio interest in the district and adjoining states should now be markedly stimulated as reception in this section has been unsatisfactory due to "dead spots" in the ether which act as a barrier between the local receiving stations and broadcast stations in New York and elsewhere.

Not only will Washington and vicinity have adequate radio service, but to every corner of the United States, this powerful station may carry the words of great men in political and diplomatic life, the progress of world events as they transpire and the music of other nations as rendered by visiting musicians. This station provides an instantaneous link between the country's political center and every American home and a better understanding of government, of the issues involved in political campaigns, and of the questions which arise in our relations with foreign countries, cannot fail to result from its operation.

There is a wealth of material available in Washington from which to make the programs of WRC most enjoyable and educational. At once it is possible that the ceremonies accompanying the dedications of memorials to great Americans, the features of the many conventions held in that city, and the spiritual counsel of the clergy may be carried to the transmitter and set forth so that the whole country may hear and appreciate them.

Momentous events, of interest to the nation, do not occur every day. The greater part of this station's operating hours will be devoted to the broadcasting of the musical and dramatic talent of Washington and other events of special interest to residents of that city. Washington is rich in both professional and amateur talent and every effort will be made by those in charge of station WRC to arrange programs so that those local interpreters of music and drama may be heard from time to time not only by their fellow-townsmen but by citizens of neighboring cities.

The studio, as well as the transmitting apparatus and office, is located in one section of the building. The studio is of acoustically correct construction and prevents even the minutest echo which might otherwise blur the clearness of transmission necessary to enjoyable entertainment.

This room is a very vital part of the several broadcasting stations of the Radio Corporation of America. Behind several huge panels are vacuum tubes of medium size used to strengthen or amplify the electrical currents which carry voice or music before actually reaching the transmitter. Their use is especially necessary when the program is being brought to the station over a wire a few miles in length, otherwise there would be insufficient energy to materially affect the radio waves. Used in connection with programs taking place in the studio, they are invaluable. The artist may move away from the microphone, may sway closer to it in his earnestness, but by a touch of a knob, the man at the control board can offset these variations.

Close to the operator, and occupying the greater part of the room, are the powerful transmitters. Although but one will be in use at any time, two complete sets are provided that a reserve unit may be in instant readiness should the active set fail for any reason. It is planned to operate these outfits alternately on alternate days. Either set is the equal in power, range and clearness of any now in use, being rated at 500 watts effective output, but if the two sets are combined for the broadcasting of some special event, the range of this station will far surpass that of any other in the country.

Each is complete in itself and contains all necessary tubes, inductions, condensers and transformers, this equipment being mounted behind a large panel and completely shielded by a perforated steel cabinet. This not only eliminates any chance of interaction between the radio-and audio-frequency currents, but protects the operators from accidentally coming in contact with bare surfaces carrying 2000 volts.

The operating table is in front of the transmitters and on it is a small box through which the operators may throw in either of the powerful transmitters and listen to the outgoing program at various stages of its progress. On this table also is a microphone that the operator on duty may cut-in and talk to the "unseen audience" himself should this be necessary at any time. By means of an intercommunicating phone he may talk to office, studio and reception room or be called by them. Because the law requires that a transmitting station must constantly listen-in for distress signals from ships, a highly efficient receiver is provided.

The motor-generators are housed in an adjoining sound-proof room, that their low hum may not disturb either artists or operators. Two machines are provided, one for each transmitter. Each of these powerful units consists of a single motor driving two generators, one of which supplies 2000 volts for the oscillator and modulator tubes and 1000 volts for the amplifier tubes, while the other furnishes the 125 volts used to operate the automatic relays and the 88 volts which heat the filaments of the large vacuum tubes.

A unique feature of this station, and one which further assures perfect transmission of programs, is a device known as the oscillograph, by which the operators have before them "a working picture of the voice." The delicate instrument may be switched into any one of the many circuits and shows, by means of an undulating, ever-varying beam of light, exactly how the artist's voice or music is affecting the electrical and radio currents. By watching this little tell-tale beam, as reflected from revolving mirrors, the observer knows instantly whether the sound waves are too weak, too great in volume or blurred.

A Workable One-Control Set

By Byrt C. Caldwell

THE tendency in the design of radio sets today seems to be towards simplicity of control and low cost of operation. The set which will ultimately win the stamp of approval from the millions of radio fans, and which will be accepted as the final word in radio receiving sets will be a one-tube set, capable of

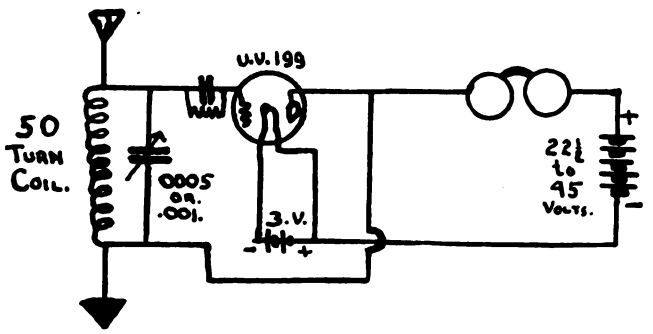

Fig. 1. Circuit diagram for the single control set. Note that the only variable feature of the set is the condenser dial, even the rheostat being done away with.

receiving several thousands of miles, and of using a loud speaker on the local stations—a set which requires no filament battery, only a low voltage B battery, and which has only one control. This set is far from being only a fantastic dream. We are already far on the road towards the realization of such a set as this, and it will not be many years before the seemingly impossible has been accomplished.

With all this in mind, the writer designed a one-tube, one-control receiver which brings in the distant stations, has a low initial cost, and an almost neglible cost of upkeep. The set is a single circuit regenerative, using a honeycomb coil (or spiderweb) for inductance, and a UV199 or C299 tube. This tube is not critical, I have found, as to plate and filament current requirements and therefore no rheostat or potentiometer is necessary. The inductance is of a fixed value and the only control is a .0005 or .001 condenser. This set is far more selective than you would suppose it to be with only one control, and with the new wave length allotments, is all that is to be desired. No interference is encountered.

The panel is size six by eight inches, and is marked out for the instruments as shown in the diagram, Fig. 2. The antenna and ground connections are at the top of the panel, and the inductance coil is directly beneath these. The condenser, which should for best results be of the two-plate mica dielectric type, is mounted under the coil, and the tube is mounted on the base. The grid leak and condenser is fastened directly to the grid post of the tube socket. The coil may be mounted either on the front or on the rear of the panel. The arrangement of the instruments given is best for short straight connections and should not be changed.

For those who wish to make the set with a one-step amplifier, I give the second diagram, Fig. 3. The set still has but one control and is made on the same size panel. The only difference is that the detector tube is moved to the left to make room for the amplifier, and the transformer and a jack is inserted in the center of the panel, so that the detector alone may be used if desired.

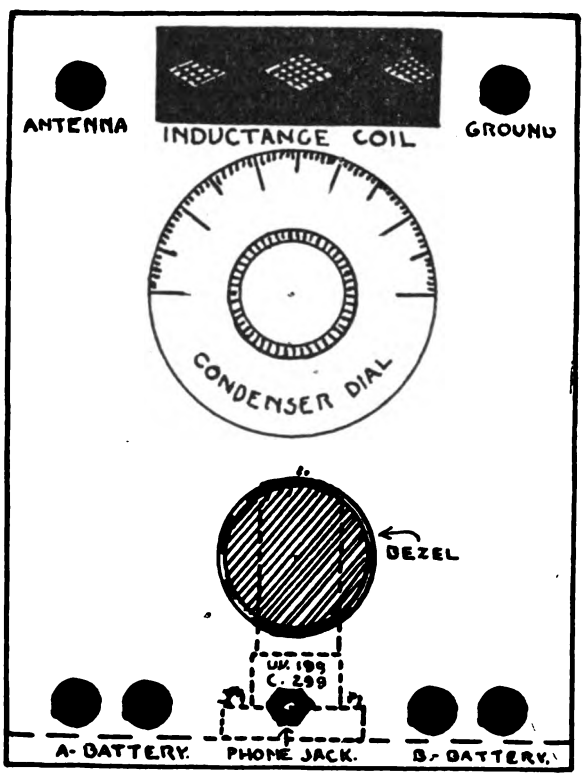

Fig. 2. Panel layout for a set embodying a single detector tube.

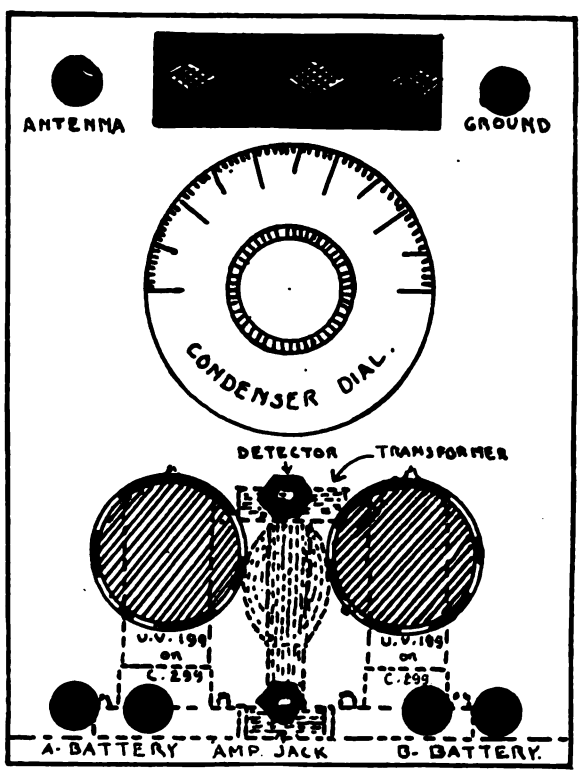

Fig. 3. Panel layout suggested for a detector and one stage set.

No hook-up is given for the amplifier, as any standard hook-up will do.

I would give the same precautions that are usually given. Use heavy wire, make the shortest possible leads between connections, and do not run two wires parallel for any distance.

No radio in Sing Sing Prison was the verdict last week of James L. Long, deputy superintendent of state prisons. This is the first official statement definitely settling whether the radio presented by the Salvation Army for condemned slayers in the death house would be installed. Several Sing Sing attaches were strongly opposed to the idea. They pointed out that, with cold-blooded murders going on outside, the impression should not be given to the criminal class that life in the death house awaiting execution is enjoyable.

PRESIDENT HARDING

WITH sincere sorrow and genuine regret, RADIO WORLD performs the duty of recording the death at San Francisco on August 2, 1923, of Warren Gamaliel Harding, twenty-ninth President of the United States.

He was a calm, urbane, courageous man with a cheerful, friendly personality that endeared him to all with whom he came in contact.

His handling of the stupendous tasks of the post-war period, enabling the United States quickly to recover from the great struggle to preserve civilization, will go down in history as the work of a remarkable man and statesman.

We have lost a great President.

(*Concluded from preceding page*)

This set is extremly easy to build. It is, however, an ideal set for the more experienced fan, as well as the youngest beginner. Its one-control makes it popular with the housewife who, during the day, wishes to listen to the numerous programs, but does not like to work away at a set of dials for a long time.

The one step of audio amplification makes it possible to use the set on a loud talker. Of course two steps of A.F. amplification may be used if desired, and radio-frequency amplification may also be added. The only changes will be an increase in the size of the panel, and a slightly different arrangement of the instruments.

Try this set. You will be more than satisfied.

Broadcasting Changes

THREE new Class A broadcasting stations were licensed by the Department of Commerce during the past week and five were transferred to Class A from Class C.

A Universal Wave Length Radio-Frequency Set

By R. L. Dougherty

TO many amateurs radio-frequency presents the only means of getting distance. They are handicapped by being in closely confined cities with tall steel buildings all around them and they know from sad experience that the regulation regenerative sets will not give them the distance they desire.

They have, however, tried radio-frequency amplification and find to their disgust that they cannot do anything with it. It seems that they are handicapped by some force beyond their control.

The probable trouble is that their radio-frequency amplifiers are sadly inefficient. They respond to waves of one length more readily than to any other. What the remedy is they do not know, and they continue to be satisfied with mediocre results until someone finally comes along and shows them a simple and efficient means of accomplishing the desired effect.

The receiver described herewith overcomes all the objections to the common brand of radio-frequency receivers, inasmuch as it will respond to 25,000 meters as efficiently as to 200, and with no extra trouble. You will be able to tune your radio-frequency amplifier to 460 meters along with your detector tube and you may be sure that you are getting all that is possible on that wave.

The apparatus needed for this set consists of: one double honeycomb mounting; one single honeycomb mounting; two tubes; two sockets; two rheostats; one .0005 variable condenser; one .001 variable condenser; one .00025 fixed condenser; one 2 megohm grid leak; one 400 ohm potentiometer.

As can be seen by the bill of materials this is to be a honeycomb coil set, and is therefore applicable to any wave lengths that you wish to listen in on.

The radio-frequency amplifier is what is known as a tuned impedance coil, and it is by this means that the wonderful selectivity is possible with this receiver. It is not only able to respond to any wave length but it can be tuned around with the rest of the receiver and the best tuning accomplished. Other stations on nearby waves will not have a chance.

Special care should be taken not to let the coil in the radio-frequency circuit be within the range of the two primary and secondary coils. If this is done, there will be feedback, and the advantage of fine tuning will be lost. For that reason the coil can be mounted in the back of the cabinet or some other out of the way place where it will not cause interference.

The set is tuned much the same as an ordinary non-regenerative circuit, varying the coupling between the primary and secondary and varying the condenser capacity.

For broadcast work the coil that should be used in the tuned impedance is DL 35 which will have a range of from 360 to 480 meters. For higher waves a 50 or 75 can be used. If commercial is desired a 100 should be used.

As a help to the uninitiated, it is always a good plan to use a size smaller coil in the tuned impedance than is used in the secondary of the coupler.

Assume that the builder has constructed his set, has paid particular attention to the polarity of his batteries and the wiring and now desires to receive signals. Turn up the two tubes, putting the condenser in the primary circuit at about 80° and the condenser across the tuned impedance coil at about 50°. Vary the coupling between the two coils until the desired station is heard, bringing it in loud and clear as possible by means of the condenser and the coupling. Then vary the condenser across the tuned impedance until it is absolutely clear, finally adjusting the potentiometer across the first tube for loudness. This completes the entire adjustment of the receiver and from that time on all the tuning is done, or rather can be done by means of the two condensers.

If the signals do not come in as clear as you would like them try using a larger tuned impedance coil. For the benefit of those who contemplate the construction of this receiver, the following honeycomb coils will allow reception over all the broadcast wave lengths: One 25 DL; two 35 DL; one 50 DL; one 75 DL. These can be purchased for a small amount and the builder will then have a receiver that is capable of bringing in the distance. If longer waves are desired the coils can

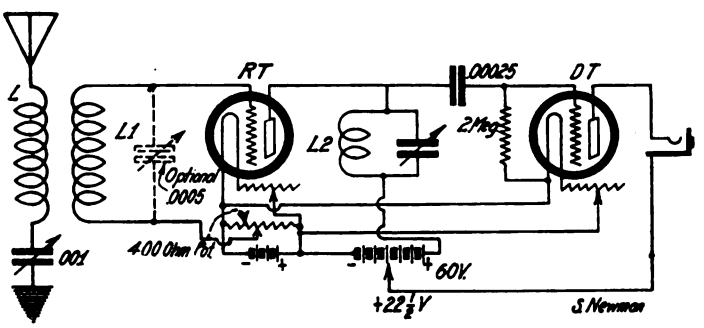

Diagram illustrating a radio-frequency set using honeycomb coils. L, primary honeycomb coil. L1, secondary honeycomb coil. L2, tuned impedance coil used as radio-frequency amplifier. The condenser shunting should be .0005 mfd.

be brought up to 750, which will then allow reception up to 3,500 meters with ease.

One point of caution for the fan who expects wonders of volume from this set. One stage of tuned impedance radio-frequency will allow greater distance than can be gotten on any single tube regenerative, but the volume will be about the same as with the single circuit set. So do not construct it with the idea that your first tube will give you signals equal to a stage of audio. It will not, but the distance over which you can hear with the circuit will be vastly improved. Radio-frequency amplification does not improve the volume of the signals as much as the distance over which they can be received, and as it is distance that is necessary to the success of most circuits, the aforementioned circuit will prove a pleasure to the fans who do not have to fill the room with music. Remarkably clear reception will be noticed, which is so different from noisy regeneration.

Maybe It's Your Grid Leak

MANY sets function poorly because the grid leak resistance is not correct. If you do not happen to own a variable grid leak, keep several fixed ones on hand, and substitute them for each other occasionally to see if you can't obtain better results.

Bureau of Mines Plans Further Radio Experiments in Interests of Life Saving

WASHINGTON, D. C.—In connection with its efforts to keep apace with all safety and rescue developments, the Bureau of Mines of the Department of the Interior is planning to continue its investigations with radio communication underground. The development of radio has been rapid and officials of the bureau feel that any application to mine rescue work must not be neglected.

Mr. J. J. Jakowsky, mechanical engineer, has been designated to undertake certain experiments in radio communication at the bureau's experimental coal mine at Bruceton, Pa. Mr. Jakowsky was attached to the Signal Corps during the war, where he had considerable experience with radio work. The co-operation of the Radio Supervisor at Pittsburgh has been promised by the Department of Commerce in the new radio experiments.

Some months ago preliminary radio experiments in sending and receiving underground at the Bruceton mine were conducted with partial success. In reporting on the matter the Bureau of Mines stated that the experiments consisted in receiving signals from without the mine by means of a receiver located inside the mine, and in sending and receiving messages underground through the strata. It was found that with a receiving instrument set at a point 100 feet underground, signals from KDKA station, East Pittsburgh, Pa., could be heard distinctly at a distance of about 18 miles from the experimental mine. In sending waves underground, a Westinghouse 20-watt B. T. model T. F. transmitter was used in such a manner as to send out continuous waves of 200 to 300 meters length. On account of the limited time no attempt was made to modify the apparatus in such a manner as to produce waves of greater length. It was found that signals could be heard distinctly through fifty feet of coal strata, but that the audibility fell off rapidly as this distance was increased. In all experiments a vertical antenna was found to give the better results. The horizontal antenna gave practically no reception. A loop of a single turn was used with fair results. All these experiments were tried with a wave length of 200 to 300 meters, except the reception from KDKA which was 360 meters. In conclusion the report stated:

"The present preliminary experiments, while unsuccessful in indicating any practical method of using wireless waves for underground communications, nevertheless indicate clearly that electromagnetic waves may be made to travel through solid strata. The 'absorption' or loss of intensity with distance is very great for the short wave lengths used in these experiments. Longer wave lengths are known to suffer less absorption and may possibly be found practically effective under certain conditions."

Transpacifics Renew Radio Contest

LOS ANGELES, CAL.—But one obstacle stands in the way of successful transoceanic traffic by amateur radio telegraph stations—direct two-way communication—and reports from Australia giving results of the Transpacific tests leave but one question in amateur circles, namely over which ocean will this final barrier be removed, the Pacific or the Atlantic? Naturally this will result in a rival contest between East and West coast amateurs of the American Radio Relay League.

Already the committee which handled the Transpacific tests in May, including the Long Beach Club of California, the management of the *Radio Journal* of Los Angeles, working with the Victoria Section of the Wireless Institute of Australia, are lining up West coast hams for another trial in October when two-way talks may be tried with Australia and New Zealand.

Reception of signals from high power amateur transmitters in the United States has aroused so much enthusiasm in the land of the Kangaroo that local hams look forward to a two-way leap in the fall, while rumors from the Radio Society of Great Britain indicate that a similar attempt will be made over the Atlantic Ocean in conjunction with American hams through the American Radio Relay League.

The race is on, with present records on either coast standing about equal, and the amateur who first succeeds in establishing two-way communication over either ocean will win the highest honors to date for the Pacific or Atlantic amateur traffic. The choice appears to be between two members of the A. R. R. L., Irving Vermilya, operator of station 1ZE at New Bedford, Mass., and V. M. Bitz, operator of station 6JD at Los Angeles, Cal.

Both of these amateurs have succeeded in sending a complete message via the ocean wave, one over the Atlantic during the famous "Transatlantics" of last year, the other over the Pacific during the "Transpacifics" just completed. Amateur radio awaits with interest the final outcome of the oceanic radio battle.

New Radio Installation at Annapolis, Md.

WORK of installing new 500 k. w. arc apparatus at Annapolis was begun by the navy recently in an effort to eliminate the local interference consisting of mush and harmonics, complained of recently by eastern commercial and private radio operators. A new building is being erected for radio operations, and here the condenser and inductor of the coupled circuit will be installed. No date of completion has as yet been announced but it is reported that the work is now going forward fairly well. Similar work will be started soon at the naval radio station in Honolulu, T. H. Eventually improvements will also be made in the set at Balboa, C. Z. Recent tests conducted by the radio section of the Bureau of Engineering at San Diego and San Francisco with up-to-date transmitting material have resulted in several improvements which will now be adapted to other important naval transmitting stations.

Latest Radio Patents

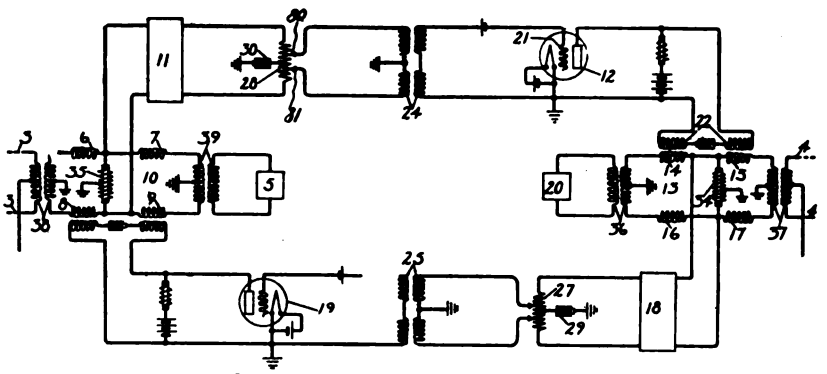
Transmission Circuits

No. 1,456,510: Patented May 29, 1923. Patentee: R. C. Mathes, New York, N. Y.

This invention relates to transmission circuits and more particularly it relates to two-way repeating systems.

As is well known in the art, it is frequently found desirable to provide a repeating or amplifying system between two transmission lines. In one form such a repeating system may have, the transmission lines are terminated in a Wheatstone bridge type of circuit for securing two-way transmission from unidirectional amplifying systems. As is well known, the conjugate condition of such bridge circuits is maintained by providing networks which closely simulate the impedance of the transmission line, or by balancing two similar transmission lines against each other. It is further well known in the art that if a high degree of conjugacy is not obtained there is a critical amount of amplification beyond which one cannot go without setting up a local circulation of energy in the form of a sustained tone, commonly known as singing, It is evident therefore that if any condition exists other than the unbalance between line and net work which causes the transmission of electrical energy between the two circuits designed to be conjugate, such a condition will further limit the amount of gain which can be obtained from the set.

It has been found in practical arrangements of telephone repeater equipment that the capacities between the primary and secondary windings of the transformers employed afford a path for the transmission of energy between the parts of the circuit presumably conjugate. As the transmission of such undesired potentials is through a series capacity, it is most efficient at high frequencies so that it may even result in a sustained singing at an inaudible frequency. This result, while not interfering as direct tone, seriously impairs the normal telephone transmission through the circuit and so necessitates a reduction in amplification.



Circuit used in two-way repeater system utilizing vacuum tubes.

In accordance with this invention, this objectionable loss in transmission efficiency of a two-way repeater circuit may be overcome by shunting these undesired potentials through a low impedance path to ground. One way this may be accomplished is by grounding one or more neutral points.

Wireless Receiving System

No. 1,455,767: Patented May 15, 1923. Patentee: J. Slepian, Swissvale, Pa.

This invention relates to amplifying devices and particularly to wireless receiving systems.

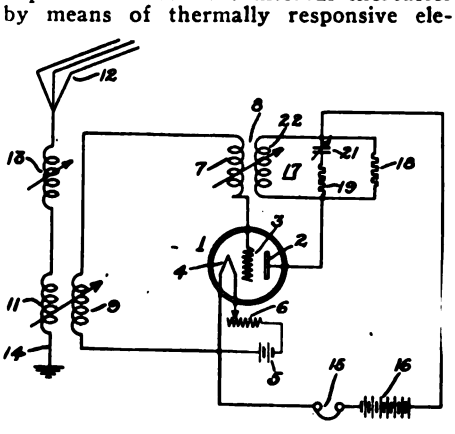
The principal object of the invention is to provide an improved wireless receiving system, wherein received signal impulses are enormously amplified.

Another object of the invention is to provide a wireless receiving system wherein undamped, continuous-wave signal impulses may be readily received without the customary heterodyning step heretofore employed.

Other objects of the invention will be apparent from the following description of the nature, mode of operation and advantages of the invention.

According to the invention, I impress the signal impulses to be detected upon a regenerative feed-back system adjusted to what, heretofore, has been considered an undesirable state, that is to say, one in which an increase in the amplitude of the oscillations causes a more than proportional increase in the feed-back power, tending to maintain the oscillations continuously.

The unbalanced condition of the system, which is effective following the application of the signal impulses, is made stable a predetermined time interval thereafter by means of thermally responsive elements having a time lag in their response. The maximum amplitude attained by the oscillations at the end of said time lag is dependent upon the intensity of the impulses tending to unbalance the system.



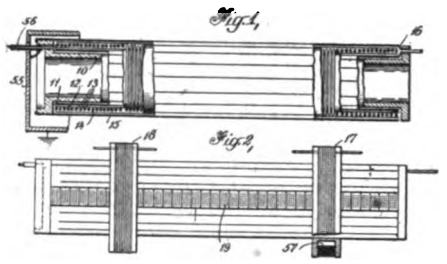
Arrangement whereby enormous self-amplification is possible on one tube.

Wave Conductor

No. 1,456,900: Patented May 29, 1923. Patentee: Michael Idvorsky Pripin, Norfolk, Conn.

This invention relates to apparatus for balancing in phase and amplitude pulsating or alternating electromotive force waves, and has for its object the provision of an apparatus of this character.

The balancing in phase and amplitude of a pulsating or alternating electromotive force wave, and in particular of high frequency waves, has many practical applications, certain of which will be hereinafter described in connection with the wave balance of the present invention. In its broad aspect, the wave balance of the present invention comprises a wave conductor having substantially uniformly distributed inductance, capacity and resistance associated with secondary circuits so arranged that the electromotive forces induced therein, by an alternating or pulsating electromotive force impressed on the conductor, can be relatively varied in amplitude and time phase. The balancing in amplitude and phase may take place directly between the electromotive forces induced in the secondary circuits, or may take place between the electromotive force induced in one of these circuits and an electromotive force modified or influenced by the electromotive force induced in the other circuit. Thus, the invention contemplates the provision of a wave balance having a wave conductor by means of which induced electromotive forces of predetermined amplitude and phase are produced from a given impressed alternating electromotive force, together with means for the utilization of these induced electromotive forces for the purpose of modifying the electromagnetic reactions in electrical circuits, which are subject to the action of the impressed electromotive force.



Apparatus used as a wave balancer.

More Artificial Static

EDITOR RADIO WORLD: I have noted with interest the words of one of your readers, who stated that to chew on celery or a nice, hard apple while receiving a church sermon will result in not being bothered with interference.

I am very fond of popcorn and had been in the habit of making a Sunday evening meal on the fluffy stuff. However, I found that whether listening to a sermon or anything else while chewing on the popcorn, the static was something awful. If anyone who has a receiver is not yet fully aware of the noises he receives in his set that are referred to as static, let him set a pan of juicy popcorn by his side while trying to listen to something he is very anxious to get, and he will have a fairly good imitation of static.

With apologies to no one, I remain

Yours very truly,
R. J. McCUTCHEON.

The Colorado Fuel & Iron Co.,
Pueblo, Colorado.

P. S.—The popcorn being popped is a very good imitation of the kind of static I have been getting for the last couple of nights.

Answers to Readers of Radio World

I built the White Circuit described in RADIO WORLD *for April 14 and have had good results. I live in an apartment house and have tried using the water and gas pipes as a ground. When I connect it to either of these I get the 110 volt hum. I cannot get an outside ground, yet cannot use either of these. Can you suggest some way of getting around my trouble?—(Unsigned letter.)*

The only manner in which you could stop your trouble is by using a counterpoise, or adapting your set to a loop antenna.

* * *

Is it possible to use audio-frequency amplifying transformers in radio-frequency circuits? Can a potentiometer be used as a rheostat? Can I use a six ohm rheostat as a potentiometer? Will an old-fashioned loosecoupler primary wound with 300 turns of No. 20 DCC wire on a tube seven inches in diameter, secondary wound with 450 turns of No. 26 DCS on a six inch tube and tapped every inch of winding allow me to receive phone music on 360 meters? It is to be used with a Fleming type valve detector.—Guy de Laufellet, Baton Rouge, La.

It is not possible to use audio-frequency transformers in place of radio-frequency transformers. The resistance in potentiometers is extremely high, and if used in place of rheostats they would have so very little of their useful resistance used that it would be negligible, as five or ten turns of the wire would be all that could be used. A rheostat cannot be used as a potentiometer. The coupler you mention is entirely too large for work on the wave lengths you specify. The dead-end loss in couplers of that size is so large that it would cut your volume and range down immensely, especially as you intend using a Fleming valve detector, which we take to mean the two electrode type which is only slightly more sensitive than a crystal detector.

* * *

Which is more sensitive, a galena crystal or a zincite-bornite combination? Is it always necessary to shunt the phones in a crystal circuit with a condenser? Where is the best place to locate a 43 plate condenser in a set consisting of a coupler, crystal detector, fixed condenser, phones and lightning arrester?—Leonard Hirtz, Albany, N. Y.

The galena is slightly more sensitive, but the combination has the advantage of stability which more than overcomes the very slight difference. Of course you understand that in crystal detectors the whole secret of success depends upon the crystal, as it is sometimes necessary to go through pounds and pounds of the raw mineral before finding one suitable sensitive crystal. Most all of the crystals sold are sensitive, but even tested minerals vary greatly. It is not absolutely necessary to shunt the phones, but the added clearness of reception fully warrants it. Suggest that you connect your condenser across the secondary of the coupler.

* * *

In one of the articles written by J. E. Anderson he mentions making neutralizing capacities by winding two lengths of insulated wire together. What length wire should be used when making these?—Charles Kouff, Pittsburgh, Pa.

You will have to find the correct capacity for your particular tube by winding various lengths together, but two pieces 2½ or three inches long should serve the purpose, winding or unwinding them until the correct capacity is found. An easier and much better method of making neutralizing capacities was suggested in RADIO WORLD for June 9, page 9, by the same writer.

* * *

I am located three houses from the local telephone exchange. Every evening at about 9 P. M. they start their generators. I can hear these all over my set, no matter how I tune. My antenna is 60 feet high and 75 feet long, and does not cross any telephone wires that are exposed. Is there any way to alleviate my trouble, other than using filters or tuned choke coils in my antenna circuit, as neither of these work? Would the use of a loop be of any help?—M. Blumenthal, Bronx, N. Y.

Since you mention that filters and choking systems do not have any effect, the only probable solution to your problem lies in the use of a loop. You might, however, before doing that experiment with a counterpoise instead of a ground as it may be that your trouble lies in the fact that your ground and the ground of some part of the telephone system interlink in a manner to cause your trouble. If a counterpoise does not help you out your only solution is a loop receiver. You might inform the telephone engineers of your trouble, and they might be able to help you, and at the same time correct some trouble of their own that they are unaware of.

* * *

Is there any reason for my getting clicks in my set every time the elevator in the building runs up and down? It seems to vary in wave length, being at its highest when the elevator is at the bottom, and gradually going down to about 100 meters when the elevator is at the top floor. How can I remedy this?—Harry Silvertine, 370 Broadway, New York City.

The cause of the noise is the fact that the motor of the elevator is sparking at the commutator, and the cables are acting as an antenna. When the elevator is at the ground floor the cables are longest, and when at the top they are shortest. Remove your antenna from the proximity of the elevator penthouse as far as possible, and also tell the elevator man that he has sparking brushes and to have them corrected. Try using a different ground. You may be getting the clicks due to the fact that the ground you are using is in some manner connected with the iron work of the elevator system.

* * *

I have my set in the car, using a loop antenna for its operation. When running the car I get induction from the spark coils. Can this be due to the fact that I am using the same battery to light my tubes as the one which runs the car? Will grounding one side of the loop as suggested in several technical articles remove my trouble? Would shielding the filament battery be of any use? —J. Namara, Pittsfield, Pa.

The induction you note might be due to the fact that you are using the same A battery for both the car and the tubes. Try using separate batteries. Grounding one side of the loop will not help, and may short your battery if one side of the battery uses the frame of the car as a ground as some cars do. Shielding the battery would be of no use as you are not getting induction from the battery, but the induction coils. Examine the high tension coils carefully and see if they are not sparking unnecessarily. If they are take a small flat file and file the interruptor points smooth and readjust so that they do not spark. You must have some direct connection, otherwise you would be able to tune it out. It is the best practice to use a separate battery in a case of your kind.

* * *

In RADIO WORLD, *June 23 you published a circuit diagram of the three tube De Forest D7 reflex. What ratio are the transformers? Are all three tubes of the hard type? Should the R. F. transformers be of the reflex type? Can W. D. 12 tubes be used? What are the two large black dots at the left hand side of the diagram? What is the capacity of the variable condenser? What is the size of the condenser across the secondary of the last transformer? What wave length does this set tune to using a loop? Using an outside antenna? How does this set compare with a set using detector, two stages of R. F. and two stages of audio? What size panel should I use? Is single control for the filaments better than separate control?—D. J. Smith, Blackfoot, Idaho. Box 427.*

We presume you mean the ratio of the audio-frequency transformers. If you use about 4½ or 5 to one transformers it will be O. K. The three tubes should all be of the amplifier or hard type. It is not necessary that the reflex type transformer be used. You can use the W. D. 12 tubes with this set. The two dots are just a way of showing that the tuning unit can be separate from the set if necessary. They signify connections. The variable condenser should be .001. The fixed condenser should be .002 mfd. Using the proper wave length radio-frequency transformers this set will respond to waves up to 600 meters, whether using antenna and ground with coupler, or loop. It is more efficient than a set using two stages of radio, detector, and two of audio, inasmuch as you are using three stages of radio, crystal detector, and three stages of audio-frequency. We cannot specify what size panel to use, but by careful constructional work and planning, you should be able to accommodate the whole set to a panel about 12 by 12, which is the size of the manufactured set. Single control is advisable as it simplifies the controls, and as all tubes are operated at the same temperature, nothing will be gained by using separate control.

* * *

In regard to the circuit diagram published in RADIO WORLD, *Jan. 20, by Ortherus Gordon, would it be advisable to use DL 75 and 100 in order to meet the new wave lengths? Would two stages of audio-frequency be sufficient to operate a loud speaker? Would W. D. 12 tubes function properly as amplifiers? Where can I obtain a circuit diagram of two stages of audio-frequency to use with this circuit? I have all your numbers.—Don Roy, 1857 E. 19th Street, Cleveland, Ohio.*

You can use these coils for the new wave lengths. You will have sufficient amplification by the use of two stages to operate a loud speaker. The tubes you mention will work satisfactorily. You will find the circuit diagram for two stages of amplification on page 26 of RADIO WORLD, March 31. Take out the grid leak across the first transformer.

* * *

In the July 14th issue of RADIO WORLD *you publish a circuit by A. D. Turnbull. He uses a potentiometer, but I am puzzled as to the connections. Should the two outside connections, or one outside and one inside connection be used?—G. D. Somprey, 1332 S. Peoria Ave., Tulsa, Okla.*

Use one side of the resistance. The other connection is the one that connects to the slider.

Digitized by Google

True Piano Music from New Microphone at WGY

TRANSMISSION of true piano quality has been a real problem for the radio engineer. The difficulty is similar to that which has confronted the maker of phonograph records. The blows of the hammers on a piano are distinguishable, but the singing quality and the overtones which are relatively weak have not been reproduced through loud speakers or phones.

P. R. Fortin, of the radio department of the General Electric Company, has devoted a great deal of time to the solution of the problem, and he has now developed a device which will make the piano solo a real feature of a broadcasting program.

The device, in brief, consists of a magnetic system between the poles of which is pivoted a suitable coil system. The magnet is firmly fastened to the frame of the piano and the coil is anchored to the sound board. By means of this pick-up device all tones in the piano are faithfully converted into corresponding electric currents which control the radio transmitter. When heard on the loud speaker the piano is no longer a tinkling sound. The listener gets all the characteristics of this percussion type of instrument, the blow of the hammer, the singing tone and the overtones.

The piano pick-up is free from the familiar hiss of the carbon microphone as well as the objectionable blasting that takes place when an artist plays too loudly for the microphone.

When the carbon or condenser microphone is used to pick up a vocal solo with piano accompaniment the problem is to place the microphone in such a position that it picks up both voice and instrument in their proper ratio. The position of the microphone must be changed for each artist. The radio listener has probably noticed that as the singer increases the volume the accompaniment fades out, in other words the soloist "paralyzes" the microphone. When the piano magneto-microphone is used the intensity of the piano may be adjusted electrically in the control room, even while the selection is being rendered, as the voice is recorded on the customary carbon or condenser microphone.

In the grand piano at WGY there are three of these devices, one in the extreme treble, one in the middle register and one in the base. These three outputs can be readily balanced in the control room for the best results on receiving sets without tampering in any way with the instrument.

Another feature of the magneto-microphone is that it allows WGY to correct for the shortcomings of the present loud speakers. All loud speakers subdue the sounds of lower frequencies, from approximately middle C on the piano down. To give good piano music for users of the loud speaker it would be necessary for the transmitting station to distort the music from the instrument, making the lower section of the piano several times as loud as the treble. Some stations have actually tried to regrade their pianos to improve them for broadcasting. This means that the music, as heard by the musician at the keyboard, is distorted and the good musician, even though convinced that his radio audience is getting perfect tones, cannot do his best work on a regraded piano.

The magneto-microphone may also be used in broadcasting phonograph music where the federal license of the station permits the use of "record" music. When the carbon microphone is used the mechanical energy of the phonograph is converted into sound energy in the usual way and is picked up by the microphone. With the magneto-microphone the needle is attached to the coil and the mechanical energy is converted directly into electrical energy without recourse to any sound whatever, thus giving truer production of the record. By proper design and the use of suitable filters in the electrical circuit of the coil a large amount of the needle scratch may be eliminated.

Put Your Electric Fan on the Floor

THE whole theory of placing electric fans high up in a room to cool it is wrong, is the contention of Julius Wodiska, a veteran manufacturing jeweler of New York. Mr. Wodiska's mechanical bent is attested by the numerous patents he has taken out from time to time outside the field of jewelry. His receipt for a cool room, as given to the New York Times, is this:

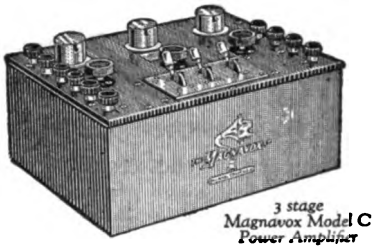
"Open the windows half way from the top and half from the bottom. Then place the fan in a convenient place on the floor. It is commonly known that heated air is much lighter than cold air and that, for that reason, heated air in a room accumulates from the ceiling down. If the upper parts of the windows are closed, the heated air has no way to escape, and the room will be filled with it until it reaches sufficient volume to extend down to the lower, or open, part of the window.

"Under the present system of placing electric fans about two-thirds of the way up the wall, the heated air is driven down and reinhaled by the occupants of the room. Under these conditions the room remains as hot as though there were no fan at all. By opening the windows and placing the fan on the floor, however, the heated air is forced out through the upper part of the window. Fresher and cooler air comes in through the bottom to replace it, and is kept fresh by the whirling fan blades. A room treated in this way will be from five to ten degrees cooler than when the fan is placed where most persons use it. Where there are children, the fan easily can be guarded and accidents avoided."

Naval Radio Efficiency Increasing

NAVAL radio communication efficiency is increasing daily according to Rear Admiral A. H. Robertson, U. S. N., Assistant Chief of Naval Operations. Recently the battleship "Oklahoma," at anchor off Bainbridge Island, Puget Sound, sent an important dispatch for the commander of the battle fleet then at sea off California. The dispatch was relayed three times going down and the answer three times returning; but the reply was received in two hours and twenty minutes. From the "Oklahoma" to Radio Station Puget Sound the message went direct, being relayed to San Francisco from Puget Sound, thence relayed to the battle fleet, consuming one hour and forty-four minutes. Most of the time was consumed in clearing the message from Puget Sound. The return message was faster, requiring only sixteen minutes. The Admiral evidently took twenty minutes to read and answer the dispatch.

MAGNAVOX
Radio Products



3 stage Magnavox Model C Power Amplifier

The Power Amplifier for your Magnavox Reproducer

The Magnavox Power Amplifier Model C, as illustrated, is a true Power Amplifier, and free from elements of distortion.

Switching from stage to stage is made easy by master switches. Any standard amplifying tube can be used.

Without Magnavox equipment, no Radio receiving set is complete.

Magnavox R3 Reproducer and 2 stage Power Amplifier . . . **$90.00**

R2 Magnavox Reproducer with 18-inch curvex horn: the utmost in amplifying power; requires only .6 of an ampere for the field **$60.00**

R3 Magnavox Reproducer with 14-inch curvex horn: ideal for homes, offices, etc. . . . **$35.00**

Model C Magnavox Power Amplifier insures getting the largest possible power input for your Magnavox Reproducer.

AC-2-C, 2-stage, $55.00
AC-3-C, 3-stage, $75.00

Magnavox Radio products can be had of good dealers everywhere. Write for copy of our new booklet.

Radio Literature Wanted

Manufacturers of and dealers in radio apparatus and accessories are notified that literature and catalogues describing their products have been requested, through the Service Editor of RADIO WORLD, by the following:

E. Baier, 4554 Park Ave., New York City.
Gerald R. Hough, 188 Lembeck Ave., Jersey City, N. J.
G. Erickson, 1708 Winona Ave., Chicago, Ill.
N. D. Lacey, Bevington, Iowa. (Retail builder.)
J. C. Lamey, 1521 Thirty-first Ave., Gulfport, Miss.
Geo. Kane, 178 Randolph St., North Abington, Mass.
Carleton E. Brewster, Jr., 78 Main St., Bay Shore, Long Island, N. Y.
Maxwell K. Murphy, 2 Orange St., Eastport, Maine.
John Hurley, 94 Parker St., Pittsfield, Mass.
G. B. Gilchrist, 141 Grove Ave., Prescott, Arizona.
Fred Gurgenson, 278 Poplar St., Roslindale, Mass.
William E. Dennis, 6141 Webster St., Philadelphia, Pa.
Roger W. Kingrose, 81 Woodward Road, Providence, R. I. (Distributor).
J. W. Mitchell, Stoughton, Mass. (Retailer. Wants condensers and other radio goods).
E. K. Roth, 301 Atlas Bldg., Tulsa, Oklahoma.
Charles W. Rankin, 2AZO, 221 Union St., Hudson, N. Y. (Interested in both transmitting and receiving parts).
M. H. Schafer, 16 Viola St., Providence, R. I.
Albert J. Kissinger, 123 Loepere St., Buffalo, N. Y. (Builds sets).
La Compagnie Radio-Concert, 20 Ave. Laviolette, Trois-Rivieres, Quebec, Canada. (Retailers).
Harold W. Offins, Dorris, Calif. (Manufacturer and dealer. In the market for panels, knobs, pointers, dials, sockets, metal inserts, moulds, moulded composition, etc.)
Wm. Schwarz, Cochecton, Sullivan Co., N. Y.
P. L. Spencer, 4129 North Eighth Ave., Birmingham, Ala. (Wants dealers' proposition.)
V. C. Wilson, Gilmor Pharmacy, Newcastle, Neb. (Dealer.)
Philip T. Downes, 197 West 134th St., New York City.
L. E. McConkey, Box 7, Mehan, Okla.
Davis Chipps, 815 Jackson St., Corinth, Miss.
R. R. Giles, 2414 Danforth Ave., Toronto, Ontario, Canada.
Charles W. Cartwright, Jr., 31 Dunlap St., Dorchester, Mass. (Radio equipment, repairs, supplies.)
Clement E. Anderson, Unionville, Mo. (Will start a small radio retail business.)
A. B. Niess, 1307 Spring Road, N. W., Washington, D. C. (Will build several sets. Wants contract with retailer of copper ribbon for loops.)
Earl R. Stright, 812 South Peag St., Dallas, Texas.
Mobile Optical Co., Mobile, Ala. (Want jobbers' prices on parts, wire and complete sets.)
F. G. Lacey, 139 East 36th St., Indianapolis, Ind. (Interested in best goods only.)
A. S. Waterbury, Perry, N. Y. (Retailer—wants to hear from manufacturers and jobbers.)
B. R. Stiles, Box 296, Moville, Iowa.
William Clyburn, 67 East Boulevard Drive, Atlanta, Ga. (Wants agency for radio products.)
Lewis Rogers, Genesee Apartments, Lockport, N. Y.
J. E. Pratt, 512 Marie Avenue, Avalon, Pa.
George J. Boehm, 25 Russell Street, Brooklyn, N. Y. (Retailer and builder of sets.)
George J. Reinhart, 55 Kirkpatrick Street, Buffalo, N. Y.
E. E. Sweet, 920 East 19th Street, Minneapolis, Minn. (Wants wholesale prices.)
Bennie Rudner, 64 Hand Street, Rochester, N. Y.
E. E. Schwartz, 1103 Twenty-fourth Street, Des Moines, Iowa.
L. H. Haselton, 33 Elm Street, Keene, N. H.
Edward G. Beverstock, Minsonville, N. H.
Edward MacFaul, 1633 Linwood Avenue, Niagara Falls, N. Y.
The Claritone Co., 425 Temple Court Building, Minneapolis, Minn.
B. B. Wilcox, P. O. Box 189, Duluth, Minn.

Wants to Sell Radio Parts

EDITOR, RADIO WORLD: For the past year I have been selling radio parts during spare time. I would like to hear from manufacturers and jobbers having good propositions to offer.

Yours truly,
ARNOLD BLAESE.
Franklin Hotel, Valparaiso, Ind.

Radio Trade Notes

Poster & Co., of 552 Seventh Avenue, New York City, well known in the panel business, announce that they are moving to larger quarters at 61 Duane Street.

* * *

E. B. Mallory, Manager Radio Sales, Westinghouse Electric & Mfg. Co., was elected chairman, Radio Section of the Associated Manufacturers of Electrical Supplies, at the annual convention held at New London, Conn. Mr. Mallory, accompanied by Meade Brunet, District Manager, Radio Corporation of America, is leaving at once on an extensive tour of the Middle West to make a thorough study of the market conditions in that territory.

* * *

Minnesota Radio Co., 20 West Lake Street, Minneapolis, Minn., jobbers, want prices on a long list of radio supplies.

The Spielman Electric Co., Inc., has removed to new and larger quarters at 311 West 59th Street, New York City.

* * *

Cape Cod Radio Supply Co., Wood's Hole, Mass., is reported to be in the market for an extensive list of radio supplies and parts.

* * *

Standard Electrical Supplies Co., 11 Moore Street, New York City, want agencies for various radio parts.

* * *

G. H. Fischer & Co., 317 Cypress Hills Road, Glendale, Long Island, N. Y., is in the market for small aluminum castings.

* * *

S. A. Twitchell, 1925 Western Avenue, Minneapolis, Minn., wants a machine for winding honeycomb coils; also is in the market for radio parts and name plates.

* * *

Robin Radio Shop, 3602 Fifth Avenue, Pittsburgh, Pa., wants quotations on electrical measuring instruments and various radio parts. Interested in a machine for engraving panels.

* * *

American Druggists Syndicate, Long Island City, N. Y., is in the market for aerial wire in large quantities.

Campaign Begun Against Fake Radio Apparatus Makers

THE initial move in a far-reaching campaign against the practice of selling fake radio apparatus was made last week, when Judge Boettner in the First Criminal Court at Newark, N. J., held Robert and Elmer Levy of the Randel Wireless Company, 9 Central Avenue, that city, in $2,000 bail each for the Grand Jury on a charge of selling wireless headphones bearing the name and other trade designations of C. Brandes, Inc., of New York City, for many years manufacturers of radio headphones.

During the course of the hearing testimony was introduced bearing upon the purchase in the Randel store of a pair of fake Brandes superior receivers, which were introduced as evidence and identified by Everett D. Holley as having been manufactured by the latter in his factory in Newark.

Mr. Holley testified that some time in March he received a visit from Robert Levy and a second man, whom Levy introduced as Mortimer Salzman. Holley testified that Salzman was represented in the introduction as a Brandes distributor. Holley related that he was asked to make up 2,000 headsets with the Brandes Superior stamp on them, the understanding being that the order was to be increased to 50,000. Delivery of 1,400 of these headsets was made to persons who identified themselves to Holley by presenting one-half of the card of the Randel Wireless Company, which previously had been torn in half, one part being retained by Holley and the other taken away by Levy.

Expert testimony as to the differences between the genuine and spurious phones was offered by Cecil E. Brigham, chief engineer of C. Brandes, Inc., who said that the diameter of the sound holes in the caps of the spurious phones was larger than those in the original. The screws holding the mechanism in the cups are much larger and not nearly so close to the surface as in the genuine, the cords are of cheaper construction and are weak and uncovered at the studs in the spurious phone, whereas in the genuine the construction is much stronger and durable. Mr. Brigham also pointed out differences in the stamping on the case, the words "Pat. pending" and "Made in U. S. A." being of larger type in the spurious than in the genuine.

Salzman, who waived examination at the hearing, was held in $500 bail and Holley is also held in $500 bail in connection with the fraud.

Arrests in the case were made following an investigation which began with tracing a thin strip of cloth binding used in the construction of the cartons containing the spurious phones. These cartons were also closely counterfeited, practically the only difference being the style of the type used.

Theatrical Managers Now Becoming Interested in Radio As Broadcasters

THE announcement made by Marcus Loew last week to the effect that he had arranged with George Shubel to transfer the WHN station from Ridgewood, L. I., N. Y., to Loew's State Theatre Building on Times Square, New York City, was a surprise to those who have not known of Mr. Loew's interest in radio.

Theatrical managers and producers have been holding aloof from radio, and in several instances have declared their antagonism to the entertainment furnished by broadcasting. Mr. Loew's announcement, therefore, that he is to furnish many of the headliners and the State Theatre orchestra as a part of the WHN programs is all the more interesting. Mr. Loew promises also to furnish other celebrities of the stage and screen for short talks at WHN. This manager, by the way, is one of the principal stockholders in the Metro Pictures Corporation, which controls the services of several eminent screen stars.

It will be interesting to note what other managers will do in the field of broadcasting now that Mr. Loew has thrown his hat into the ring. At least one owner of several legitimate theatres has declared that he is going to establish one of the biggest broadcasting stations in this country.

RADIO WORLD may have something interesting to say in an early issue regarding a new booking office, through which talent for broadcasting is to be booked in the same manner as the business is conducted by the big theatrical booking agencies.

Kansas City's Mayor Strong for Broadcasting

EDITOR, RADIO WORLD: I will answer your letter of July 23 by saying that if all the chief executives of our American cities should have an experience similar to mine in broadcasting civic news through the medium of civic night programs, and if results as brilliant should accrue to their credit, I know they would all "pull for" and would attain a municipally owned broadcasting station in short order (providing, of course, that their funds would permit).

Yours sincerely,
FRANK H. CROMWELL,
Kansas City, Mo. Mayor.

Broadcasting Interesting to Camden's Mayor

EDITOR, RADIO WORLD: Your letter of July 24th instant received, and the proposition of a municipally owned and operated radio broadcasting station is indeed interesting.

Of course, radio broadcasting is in its infancy, but no doubt greater things than we can picture will be developed from it.

Very truly yours,
VICTOR KING,
Camden, N. J. Mayor.

Vessel Propulsion by Radio Is Forecast

THE next step in motive power for engines on transatlantic liners will be electrical propulsion by power received by wireless from power stations ashore."

This was the belief of Giuseppe Fatterini, Chief Engineer of the Vacuum Oil Company in Italy, who sailed last week on the steamship *Colombo* for Genoa.

Electrical propulsion from shore stations will come to pass within fifty years, was the belief of Mr. Fatterini, as expressed to the New York *World*.

"Recent experiments in Germany and France of driving an airplane by electrical energy furnished from the ground," said Mr. Fatterini, "paves the way for experiments for driving steamships across the ocean by power from shore stations. Another big thing is the extraction of vast power from water by atomic combustion. In a quart of water there is enough atomic power, if extracted, to give out the energy of 300 tons of coal."

Of Interest to Dry Cell Tube Users

THE Radio Equipment Company, 630 Washington Street, Boston, Mass., have put an article on the market that will prove a blessing to the users of WD-11 and WD-12 tubes. It is a very small fuse that fits over the leg of the tube and protects it from high currents passing due to a short circuit. It is very neatly constructed of brass, so made that when it is applied to the filament terminals of the tube the current must go through the fusible material before going to the filament. An article such as this should meet with approval by the users of small tubes, inasmuch as it is said to be the first one in its field. We have had protectors for our six-volt tubes, but have neglected our 1½-volt tubes, with the result that many fans have suffered from blow outs.

No Capacity Effects

THE Thresher Radio & Machine Corporation, 476 Eighteenth Avenue, Newark, N. J., have perfected a telephone jack which has several novel and important features. It differs from all other types as its contact leaves are placed in a vertical position instead of horizontal. Due to the fact that its leaves are so placed in parallel position, those of opposite polarity are edge to edge, instead of parallel, presenting a very small surface to each other, lessening capacity effect. It also takes up very little space, and ample room is allowed for the lugs, giving plenty of connector space. The insulating material used is turned hard rubber. It is made in all the popular styles, from open circuit to double circuit closed.

New Radio and Electric Firms

Grimes Radio Engineering Co., New York City, make radio apparatus, $25,000; R. L. Bradford, C. A. Curtis, P. M. Payne. (Attorneys, Geller, Rolston & Blanc, 22 Exchange Place).

New York Institute of Electric Therapy, New York City, $10,000; S. Ginsberg, M. Finestone, S. L. Lippner. (Attorney, E. Law, 36 West 44th Street).

Rathbun Mfg. Co., Jamestown, N. Y., radio sets, $30,000; F. and C. R. and J. C. Rathbun. (Attorney, J. H. Prother, Jamestown.)

Finestar Electrical Supply Co., New York City, $6,000; L. and G. Feine, S. Starr. (Attorney, B. M. Turkat, 44 Court Street, Brooklyn, N. Y.)

Daily Newspapers Publishing Radio News and Programs

AS a part of its service to readers RADIO WORLD publishes herewith the names of daily newspapers which carry radio programs and radio news. Wherever possible the name of the radio editor of the paper is given. Additions to the list will be published as received.

Brooklyn Daily Times, Brooklyn, N. Y., carries complete radio programs. W. M. Oestreicher, managing editor.

The Christian Science Monitor, Boston, Mass., prints daily in its local edition condensed radio programs from the more important cities in the East. The radio department is in charge of the city editor.

Winsted Evening Citizen, Winsted, Conn. One of the first newspapers to print radio news and programs. Arthur L. Chapman, radio correspondent.

The Attleboro Sun, Attleboro, Mass., publishes a radio program summary and news daily with special features several times a week. C. S. Sherman, radio editor.

A Correction

ON page 20 of RADIO WORLD for August 4 there was printed a diagram of a honeycomb circuit with one stage of amplification. The manner in which the B battery of the amplifier is hooked up is incorrect. The connection running from the plus of the lower B battery which supplies the detector should run directly to the upper post of the jack, and there should be no connecting link between the plus of the amplifier battery and the plus of the detector. The connection should run directly to the upper side of the jack.

Helps to Get That Distant Station

THE Amplex Instrument Laboratories, 57 Dey Street, New York City, have recently put on the market an article called a "grid-denser." It is a very small variable condenser that is to be used in the grid circuit in place of the conventional grid condenser. Variance is made by means of a small knob. It is very neatly constructed, taking up very little space. The range is from .00015 to .0005, which is wide enough to use with all tubes on the market at the present time.

Radio and Artificial Lightning

ARTIFICIAL lightning, when it is wanted and where it is wanted, is one of the growing wants of the engineer engaged in high power radio work.

The radio engineer at the giant trans-oceanic station uses tremendous voltages for testing purposes, which at times exceed a quarter of a million volts, with the same freedom from concern as the radio fan who connects a six volt battery to his receiving set.

But the use of such unusually high potentials which, when in action, resemble a mimic electrical storm, have an important place in the laboratory and field apparatus of the modern engineering staff the chief use for which is the testing of the insulation material at the high power stations of the Radio Corporation of America. These stations are engaged day in and day out in exchanging over twenty-five percent of the message traffic between New York and four countries in Europe. In fair weather and in foul, subjected to high wind pressure, sleet and snow, the aerial insulators which hang from towers ranging in height from 350 feet to 750 feet must carry the strain of voltage which is impressed upon them with the least possible chance of mechanical or electrical failure. How shall we know whether the insulators in the antenna will safely carry their burden without electrical breakdown? They are essential to uninterrupted communications as the wheels of a locomotive are to continuous transportation. Insignificant as they may seem, elevated to great heights where they appear as mere black specks against the sky, these insulators must be thoroughly tested before installation. They must be tested under the most severe conditions that actual service might impose upon them.

The function of artificial lightning is to imitate these service conditions in the field or laboratory so as to enable an accurate observation of the electrical behavior of the insulator to be made.

It might be asked, "Cannot approximate calculations be made to show without the use of the high voltage and apparent attending hazards just how efficient an insulator is?" This must be answered in the negative. Defects of various kinds evade an attempt by the engineer to apply his mathematical reasoning with certainty.

The generator used to produce the high voltage for testing insulators has a power of 200,000 watts or over 200 horse-power. It is connected through a circuit which increases its voltage to about 150,000. The test insulator has its metal connecting ends joined to the generating circuit and the power is turned on. One of two things can happen to the insulator; it will either allow current to pass through it in which case it will explode into bits or will force the surrounding air to break down under the influence of the high potentials in which case its insulating properties are good and is acceptable for use in the aerial.

During these tests, artificial rain is produced which moistens the insulator in the same manner as an actual rain storm. If the insulator survives the wet and dry test it is fit for service and takes its place in the aerial when needed.

On one occasion at the RCA station at New Brunswick, N. J., the generator was driving an abnormal charge into the antenna when a rain storm came up and drenched the aerial insulators. This was at a time when, during the war, radio stations are most carefully guarded against damage by wartime fanatics. Late in the evening an insulator broke down under the heavy strain and crashed into bits which flew in all directions. The report accompanying the destroying of the insulator caused the military guard a great deal of confusion as they suspected a bomb had been thrown into the radio station.

Radio Replaces Flowers and Fruit at Hospital

IN the old days, when you went to see a hospital patient, you brought him food in the old-fashioned notion that hospitals neglected the culinary niceties, and it was your duty to smuggle in something that the sick person would enjoy. You knew he would, because you were bringing him his favorite dish, and you never could understand that smarty nurse's edict that he couldn't have it now.

Or you went to the florist and tried to choose between roses tied with a ribbon and carnations gracefully arranged in a basket. And you were always amazed to find that some one else had thought of the same thing, only with more success.

Now, all you have to do to be a little different is to get there first with a radio outfit, and that will soon cease to be a mark of particular attention to your sick friend unless you haul up the latest in tube sets which will "get" the Fiji Islands or wherever it is that, the most remote station happens to be.

"Sometimes we have as many as 20 sets in the hospital at once," said Miss Louise Arnold, superintendent of Ellis Hospital, in Schenectady, N. Y. "The General Electric people who have friends here bring in apparatus as soon as the patient is able to enjoy radio. Many are of the crystal type that will catch WGY only. However, as the sick are rarely here long enough to need the greater diversion that might come from being able to listen in throughout the country, they are a great help in passing time. As soon as convalescence begins, radio can be enjoyed."

Some hospitals use it in treating their patients. New York institutions report success in rheumatism and other chronic afflictions where the ether waves are made to act as a sedative. Doctors there say it has cut down the administration of drugs, because in listening to music by radio, the sufferer is made to forget his condition. Others who are in great pain find the programs an ally in stifling the complaints that are forced when the mind has nothing but pain to dwell upon.

Ellis Hospital has seen it so far merely as a diversion, one that is an unquestioned bulwark to the morale of the patient who has long hours alone. Under daylight saving, the programs begin only a little while before visitors must leave, and they continue long enough to top off a day as pleasantly as it is ended at home.

The hospital owns a portable tube set which is taken to the bedside of any patient who expresses a desire to have it and it is in use nightly.

"I read the other day about a hospital in Philadelphia where there is an arrangement whereby radio can be turned on or off anywhere in the place at will," Miss Arnold said. "The whole building is equipped, and any patient who wishes to hear the programs, is able to, while those who tire of it need not be annoyed. Maybe some day we'll have one like that."

WD-11 and WD-12

Popularity of the Radio Drama Proven

IN concluding a season's run of forty-three performances the WGY Players stepped from their parts during the production of "It Pays to Advertise," and addressed their radio listeners. Figuratively, they "stepped before the curtain" and told of the pleasure and interest they had found in this new development of the drama.

If any doubt of the popularity of the radio drama had lingered after this long run by the WGY Players at the Schenectady station of the General Electric Company, it was brushed aside by the hundreds of letters which have literally poured into the station since the announcement that the players would not be heard during the summer months. The outstanding sentiment of the letters was that the listener feels that each of the players is a personal friend. Practically the same cast has been maintained during the long run and these same voices coming into a home week after week have won recognition for the players and a place in the hearts of the listeners. Each radio fan, sitting at his set, feels that a production is something put on just for him and the curtain speeches of the actors helped to cement that feeling of friendliness which exists between performer and listener, no matter how many miles might stretch between them.

A York, Pa., correspondent remonstrates at the discontinuance of the drama as follows: "I would like to know why they (the Players) quit now. In a theatre, of course, it is too hot at this time of the year, but not where I go—my radio set. I take a seat way up front and nobody interrupts me changing seats, no women's hats get in the way, no music or candy hawkers interfere with my enjoyment; there are no long intermissions and you don't even have to dress."

"It seemed like parting with intimate friends and we shall miss you," wrote a radio fan living at East Greenbush, N. Y. "We are glad it will not be long and we shall be anxiously waiting to hear your pleasant voices again in the fall."

Since the initial performance of the WGY Players, "The Wolf," the organization has remained practically the same. Six players who have appeared during the entire season have been: Viola Karwowska, Ida Myrick, Ruth Schilling, Edward E. Schilling, Frank Oliver and Edward H. Smith, director.

The players who addressed the radio audience and who have been with the organization since the first play, "The Wolf," were: Viola Karwowska, Ida Myrick, Ruth Schilling, Edward E. St. Louis, Frank Oliver and Edward H. Smith, director.

These pioneers in the radio drama suffered at first, felt handicapped in their efforts to find inspiration from a microphone in a quiet studio. The audience was unseen and it is rather difficult to find inspiration in something silent and unseen. Then the letters began to come in and these letters established contact between performer and listener. The actor began to feel that he was addressing old friends who were tolerant of weaknesses in a production and enthusiastic when a situation in a plot was put over successfully.

Perfect Performance Guaranteed

Ace Type V, Armstrong Regenerative Receiver, $20—No receiver at its price can equal it for performance.

An Evansville man writes: "The other night I tuned in Kamach, Hawaii, and held the concert for an hour. The music was clear and the speaking distinct."

Ace Receivers are licensed under Armstrong U. S. Patent 1,113,149.

All Ace sets are equipped with the Crosley multistat, the universal filament control rheostat, for all makes of tubes.

Chicago Radio Convention Will Be Well Attended

CHICAGO, ILL. — Approximately 1,500 persons, representing all lines of radio activity, ranging from amateurs and experimenters to technical men connected with the radio industry, as well as authorities of international reputation, will attend the Second National American Radio Relay League Convention, which is to be held in this city September 12-15 under the auspices of the Chicago Radio Traffic Association, it is estimated by committeemen.

Tentative plans for the convention, which have just been made public by R. H. G. Mathews, of the Chicago Radio Laboratory, 332 South Michigan Avenue (Chicago), central division manager of the American Radio Relay League, call for a program of interest to both the amateur and the broadcast listener. A huge banquet is scheduled for Wednesday evening.

An intensive effort is being made by Mr. Mathews and officers of the A. R. R. L. at Hartford, Conn., to select speakers who will cover all phases of radio transmission and reception, bringing before those attending the convention all of the most recent developments which may be utilized for long-distance work in the early fall.

One of the most important meetings at the convention, on the afternoon of Thursday, will be that of the A. R. R. L. Traffic Department under the chairmanship of F. H. Schnell, traffic manager of the League, when coming international amateur long-distance tests and kindred matters will be discussed at length.

Radiotrons

To Get Distance—and Get it Clearly

Radiotron WD-12 The standard base dry cell tube $6.50

Radiotron WD-11 The ideal dry battery detector $6.50

Radiotron UV-199 The little tube of big performance $6.50

Radiotron UV-201-A The super-amplifier tube $6.50

Radiotron WD-200 The long distance detector $5.00

RCA

This symbol of quality is your protection

For quality of reception and length of service, every man wants a RADIOTRON. Experienced amateurs and broadcast listeners know the sensitivity and dependable performance of these tubes. UV-199 for portable sets because it operates on flashlight batteries—WD-11 and WD-12, the dry cell tubes, for use everywhere—especially on farms and at the summer bungalow—UV-200 and UV-201-A for use with a storage battery. There is a Radiotron for every need.

Look for the RCA trade mark, and the name RADIOTRON. Each is a guarantee of satisfaction.

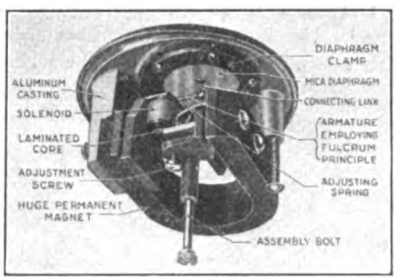
THE TRINITY LOUD SPEAKER

TYPE "A1" 21" FIBER HORN $25.00

TYPE "B" (For Phonographs) $12.50



INTERIOR CONSTRUCTION

An ear phone is an ear phone no matter how fancy the horn that covers it may be, and, due to the delicate construction of an ear phone it is utterly incapable of giving **true tone reproduction**, especially, when relatively large currents are passed thru its coils, such as the output of a two-stage or power amplifier.

The Trinity Loud Speaker element embodies the well-proven and tested principles of the phonograph reproducer with the soundest principles of electromagnetic design best adapted for loud speaker operation. It is not an ear phone when placed on a head band and a loud speaker when covered with a horn. It is a sturdy loud-speaking element ALWAYS.

Send for Literature.

The Foreign Trade Eldorados of the Future

WHERE, in the world of today and of the next fifty years, during which the contests of commercial supremacy will be fought strenuously, and, in a large sense, permanently, lie the foreign trade Eldorados of the United States?

"In Latin-America and, necessarily, by reach and by riches, mainly in South America," declares A. Guyot Cameron in Forbes Magazine, who makes an earnest plea to business men to wake up and follow example of European countries in the development of these fertile fields.

"The object lesson lies in the example of Europe. In spite of large economic prostrations, of financial constrictions paralyzing effort and almost hope, of restricted creation and distribution of products, Europe is intensively pushing its commercial relations and sowing seeds that will flower into abundant economic harvests from the fields of the future.

"Great Britain in the Argentine and in Chile; Italy in Chile and the Argentine; Spain in Brazil and Argentina, and in every South American nation of Spanish tradition; France in Bolivia; Germany in Brazil, Argentina, and Colombia; Belgium and Holland in many places are making the moves on the checker-board of export effort. At that great game, not of grab nor of gold, but of commercial generalship upon which in large measure depends international power, if the United States does not 'sit in' now, it will find places occupied. And the rules of the game will allow neither over-throwing of the board to start a new play nor displacing of the players already there.

"For it is export that gives the final profit on the total volume of industry and of commerce. Estimates of the percentage vary, but the fact remains, and has been stated again and again by captains of industry and by economic experts that export is the real key to the profits of production, taken generally."

Coming Events

AMERICAN RADIO EXPOSITION, Grand Central Palace, New York City, October 6 to 13, 1923. J. C. Johnson, general manager.

ANNUAL HOME AND CITY BEAUTIFUL EXPOSITION, featuring radio exhibits, Atlantic City, N. J., June 16 to September 8, 1923.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEER, Pacific Coast convention, Del Monte, Cal., Oct. 2-5. F. L. Hutchinson, 33 West 39th St., New York.

AMERICAN RADIO RELAY LEAGUE, second national convention, Chicago, Ill., September 12-15, 1923. Chicago Radio Traffic Association, 959 The Rookery, Chicago, Ill.

Frequency versus Wave Lengths

By C. W. Horn

Superintendent of Radio Operations Westinghouse Electric and Manufacturing Company

AUTHORITIES on matters pertaining to radio are agreed that the most logical and useful way of specifying the wave length of a radio station or transmitter is in cycles or kilocycles. This will be evident from careful study of a theory underlying the method of computing either the frequency or wave length.

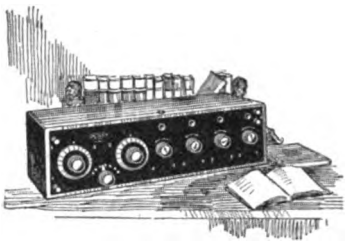
A radio wave travels with the speed of light, which we know to be approximately 30,000,000 meters per second. If the wave length of a transmitter were one meter this would mean that there would be 300,000,000 vibrations or oscillations per second, or, in other words, that the frequency would be 300,000,000. If the wave length, however, were 300,000,000 meters then it would take one second for one oscillation to take place, which would be a frequency of one for that wave length.

From the above it will be seen that by dividing the speed of electricity by the number of oscillations per second, or the frequency as it is usually called, we obtain the wave length in meters. This is the distance between two successive oscillations. If there is but one oscillation per second then the wave length would be the distance traveled in one second, which would be 300,000,000 meters. However, if there should be a million cycles per second then the distance traveled by the wave in one second divided by the number of cycles in that second would give you the wave length of one complete cycle. In other words, more simply expressed, the greater the number of oscillations in a given space of time then the shorter they must be in order to get that many in.

The greatest advantage, however, of expressing the length of the wave in frequencies is that radio formulae always call for the frequency and much time is saved. Also, if you know that your receiver will tune to within 20,000 cycles of another wave it is much simpler to note that the figure is 20,000 cycles than that it is perhaps two meters on the lower wave lengths and perhaps 200 meters on the higher wave length. For this reason it is advisable for everyone connected with radio to accustom themselves to thinking of wave lengths in frequencies rather than in meters.

National Toy Show

THE National Toy Show, which since 1916 has been held annually at the Hotel Imperial, New York City, will be held in the future at the Bush Terminal Sales Building, 132 West Forty-second Street, New York City, according to electrical toy manufacturers who during the last four years have made the largest exhibits at these shows.



TUNE IN THE WORLD WITH A CROSLEY MODEL X

No matter where you live, the news and pleasures of the world are an open book to you if you own a Crosley Model X.

A man from Belleville, Kansas, writes: "I have found the Crosley Model X to be the best radio receiving set I have used, and permit me to say that I have been interested and using radio sets since the spring of 1922, including all standard makes."

In spite of new features such as the R. F. T. A. Coil and the Multistat, the Crosley Model is still priced at $55.00.

DID YOU GET THE VACATION NUMBER OF RADIO WORLD

It had page after page of interesting and practical ideas and hook-ups for people who are going camping, canoeing, yachting, or just vacationing up in the mountains. You really can't afford to be without it, if you intend leaving the city behind this summer and want to take your radio with you. Dated June 2. Mailed for 15c.

Radio World, 1493 Broadway, New York City

Fifty-two issues for $6.00. Subscription Department, RADIO WORLD, 1493 Broadway, New York City.

Construction of New Type Transatlantic Receiving Sets

By M. B. SLEEPER

Fully Illustrated. Price 75 Cents

IN addition to the listening to ships and broadcasting stations on short wave lengths there is a peculiar fascination about listening to the high-power telegraph stations of England, France, Germany, Russia and Italy as well as those located in the Pacific Ocean and the Oriental Countries. It is much easier to do this than most people imagine. The sending is very slow, a feature of assistance to the beginner in telegraphy. Several types of receiving sets for this task are described. Detectors, amplifiers, oscillators, etc., for long distance reception are also described. Suggestions for the operation of relays by the signals and the reproduction of them on a phonograph are given. In addition there is some valuable data on home made wavemeters for testing and experimenting.

IMPORTANT NOTICE

While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

President Harding Greeted

CAPTAIN DONALD B. MACMILLAN, who is somewhere north of Labrador on his way to the Arctic where he will determine whether there is to be another ice age, has sent a wireless message of greeting to President Harding, a copy of which was received at Hartford, Conn., by the A. R. R. L.

The text of the explorer's greeting, which was sent from his schooner, the "Bowdoin," in the vicinity of Jack Lanes Bay, Labrador, follows:

"Greetings from the crew of the 'Bowdoin' from the Atlantic to the Pacific. All hope that you are thoroughly enjoying your sub-Arctic trip."

This message was forwarded across the Continent by amateur radio.

Expecting Too Much

ONE of the editors of RADIO WORLD called by telephone a prominent manufacturing company whose name features the word "radio." When the connection was established, here's what happened:

Operator—"This is Siwash 4,000."

Editor—"RADIO WORLD speaking. Is Mr. Brown in?"

Operator—"I don't get the first word."

Editor—"Radio—RADIO WORLD."

Operator—"I don't get it."

Editor — "Radio — radio — R-A-D-I-O. You certainly ought to be familiar with that word."

Operator—"Well, I'm not. This is my first day here!"

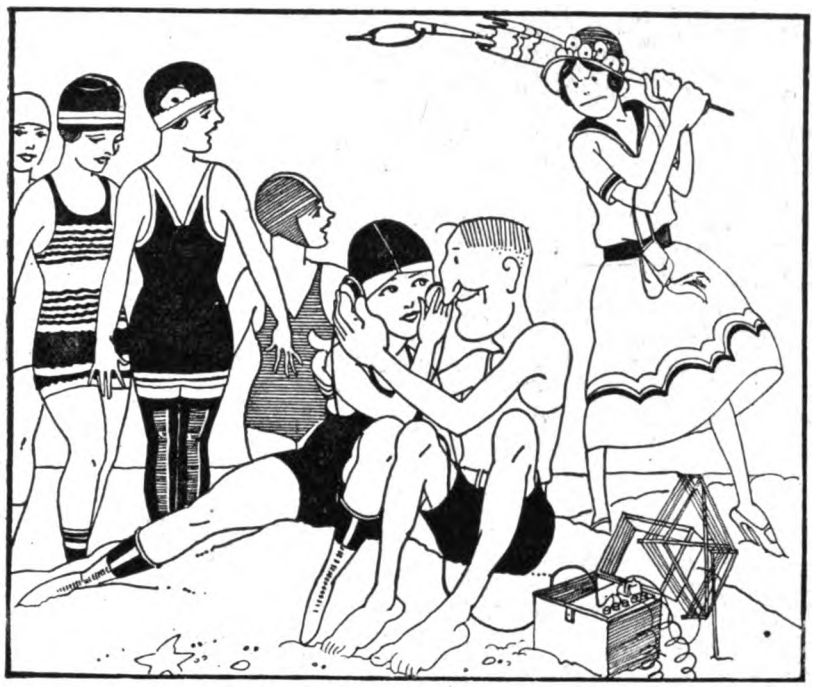
Broadcast Bill's Radiolays

By William E. Douglass



"When crack upon my dome came the blow of an umbrella."

SAKES alive! You should a seen me last week on a trip down East. Lots uf folks don't like to travel. I don't mind it in the least. Saw New York an' Coney Island, 'Lantic City an' the rest but uf all the places vis'ted I liked 'Lantic City best. Mebbe some uf you have been there. Like as not I'll go again. If I do I'll bet a dollar I don't tell nobody when. Lots uf funny things will happen when a feller starts to roam, things I never would uf thought uf in my peaceful quiet home. Why one day when I went swimmin' where the waves come rollin' in an' the sunshine, fer you know it, burns some blisters on yer skin. I attracted more attention as I sat there on the beach an' it wuzn't fifteen seconds till I'd spotted one fair peach. In the first place after swimmin' I thought I would rest awhile in the sand an' watch the bathers fer it seemed to be the style. 'Course I had my loop antenna an' my good ol' wireless set. I may leave my wife an' family but I haven't left it yet. Riggin' up the set as usual 'twuzzn't long till I "tuned in" on the local sendin station so I tuned an' with a grin sez to this here babe I'd spotted "Want to listen in with me?" "Sure" she sez (the smile she give me wuz as pretty as could be.) Since I only had one head set we were sittin' side by side, to myself I kept repeatin' "Let your conscience be your guide." 'Twuzn't long till there were others waitin' 'round so they could hear, an' my sentiments are always "Try to please the ladies dear." While I didn't mind their lis'nin', it wuz quite a pleasant duty, wuz it Radio attractin' them er just my style of beauty? Anyway I had a waitin' list of twenty-five er thirty. There were Genevieves an' Helens, Eleanors an' dainty Gerty. Things were gettin' mighty interestin' when crack up on my dome came the blow of an umbrella. 'Twuz a message "straight frum home." Next time I start out to travel, sometime I may go again to the seashore I'll just betcha I don't tell my family when.

Advertiser Reaches Army of Dealers with Radio World, a Fan Publication

SLEEPER
RADIO CORPORATION
88 PARK PLACE, NEW YORK

Radio World,
1493 Broadway,
New York City.

Attention of Mr. Clark

Gentlemen:—

Advertising is a wonderful thing but in some four years of experience in using radio and trade papers, we have never known of such instantaneous and far-reaching results as we secured from the full page back cover advertisement which we had in "Radio World" of July 21st.

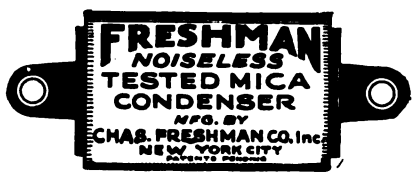
We chose "Radio World" as the quickest way of announcing the new Sleeper Monotrol which we have just perfected as the first commercial application of the Grimes Inverse Duplex Circuit. We expected that a great many would be interested in details of the new set and in the fact that Mr. David Grimes is with us as our Chief Engineer, but we never believed that such floods of letters could pour in on us so quickly. They came from practically every state in the union and what is most pleasing to us, over 60% are from dealers rather than individuals.

You are at liberty to use this endorsement of the advertising power of "Radio World" in any way you care to because you have given us results that other advertisers are entitled to know about.

Yours very truly,
SLEEPER RADIO CORPORATION.
(Signed) Gordon C. Sleeper, President.

July 27, 1923.

The Condenser Sensation of Modern Radio



Through the accuracy and dependability of Freshman Condensers, hook-ups and circuits have been perfected which have completely revolutionized the art of Radio Reception.

These little Storers of energy and rectifiers of Radio Current are the very heart of a well-built radio set.

The proper fixed condenser will make all the difference in the world in the reception, clarity and selectivity your set affords.

Capacity	Each	Capacity	Each
.0001	$ .35	.002	$ .40
.00015	.35	.0025	.50
.00025	.35	.003	.60
.0002	.35	.004	.75
.0003	.35	.005	.75
.00035	.39	.006	.75
.0005	.35	.006	1.00
.0006	.40	.01	1.00
.0008	.40	.015	1.50
.001	.40	.02	2.00
.0015	.40	.029	2.50

The FRESHMAN is so designed that constant equal pressure is exerted on the condenser plates over the entire area. They are the only condensers that do this and therefore the only condensers that avoid noises, which are due to variable pressure on the plates.

At your dealers, otherwise send purchase price and you will be supplied postpaid.

proven best filament control

—challenges the world

Proven by every test to surpass any and all rheostats and filament controls, Fil-Ko-Stat rightly challenges the world.

Laboratory research proves Fil-Ko-Stat to have a fine adjustment area (which means ability to control filament heat and electronic flow) eighteen times greater than that of the wire rheostat and several times that of the next best filament control.

Actual use proves Fil-Ko-Stat the most acurate control for any tube from "peanut" to "power." Full resistance 30 ohms.

—it has no screws or adjustments to tamper with. It is triple tested and regulated at the factory to the ideal "off" position for

UV 200, 201, 201A, WD11, WD12, UV199, DV6A, W. E. Peanut, etc., etc.

—it is non-microphonic, operates noiselessly, eliminating all "frying."

—it has no disks to break or chip and its reliability and durability are guaranteed by the manufacturer.

If you have never tried tuning with your filament control, start with a Fil-Ko-Stat. It brings in strong and clear D. X. stations you never heard before.

If your dealer has no Fil-Ko-Stats in stock, send his name and your remittance direct to

Westinghouse Stations Stand By on Friday

THE three Westinghouse broadcasting stations, KDKA, Pittsburgh, Pa.; KYW, Chicago, Ill., and WBZ, Springfield, Mass., suspended their entire broadcasting programs on Friday, August 10, National Mourning Day throughout the United States in honor of President Harding.

These stations remained silent during the whole day with the exception of Station KDKA, which broadcast a memorial service between the hours of 8 and 9 p. m. Many broadcasting stations throughout the country followed this action as a tribute to our late President.

Gen. Dawes in Tears as He Radios Harding's Praise

BROADCASTING his tribute to the late President Harding from the Edgewater Beach Hotel, Chicago, Gen. Charles G. Dawes broke down and cried as the final words died on his lips. He buried his face in his hands and his sobs went out to the mourning nation.

Gen. Dawes, who was called to Washington at the beginning of the Harding administration to establish the national budget system, completely won the President's confidence and was perhaps Mr. Harding's most intimate friend in Chicago.

Waiting his turn to speak, the man who made the "Hell and Maria" exclamation famous, was visibly under a heavy strain. When called he sat down at the microphone at Station WJAZ with grim determination on his face and began. His voice remained steady until near the end, when he referred to the love and companionship of President Harding and his devoted wife. Then his chin quivered and his voice broke. The few guests in the radio station sat in respectful silence until Gen. Dawes lifted his tear-stained face and arose with jaws set, again the soldier. He walked silently out of the little curtained room to a distant part of the hotel, glancing neither to right nor left, nor speaking a word until his wife, who followed, reached his side.

Station WBZ Broadcasts Harding Memorial Services

TWO memorial services by radio were the tribute paid to the late President Harding by Westinghouse Radio Station WBZ, Springfield, Mass., on Friday last; one in the afternoon at 2.15, broadcast from the city of Springfield Auditorium, and the other from the Kimball Hotel Studio at 8.00 p. m.

In the afternoon, the services began with ten selections on the Municipal Chime played by Bell-ringer Ernest N. Bagg. The first number was "America" and the last, "Taps." The numbers intervening were the President's favorite hymns.

After the chimes called the people of Springfield to the service, Municipal Organist Arthur Turner gave a number of appropriate selections. The meeting was opened by Acting-Mayor Frank Kinney, and prayers and addresses by prominent ministers and men of Springfield followed.

Microphones in the hall picked up the music and speeches and they were sent to East Springfield to the radio station where they were broadcast.

In the evening a similar service was given which allowed the people at distant points to hear the service. It was conducted by Rev. Stanley F. Blomfield and the music was furnished by the Springfield Conservatory of Music.

The regular musical program scheduled for the evening as well as the business talks and bedtime story for the children were cancelled so that due homage could be paid to the late President.

Forthcoming Program at WGY

SUNDAY morning, August 19, the Rev. Dr. George Alexander, pastor of the First Presbyterian Church of New York, will deliver the sermon at the service of the First Presbyterian Church of Schenectady, to be broadcast by WGY, the General Electric Company radio station.

For the convenience of farmers WGY has made changes in time schedule of produce market reports, harvest and regular weather forecasts. These reports will be sent out from 12:01 to 12:20, eastern standard time.

Ray Halse's orchestra will offer a program of popular dance music Monday evening, August 20.

Members of the WGY Players will present a Shakespearean program Tuesday night, August 21. Readings from "Midsummer Night's Dream," "Romeo and Juliet," "The Merchant of Venice" and "Twelfth Night," will be given.

Thursday evening Rogers Whitmore, a young violinist of Ilion, N. Y., will be featured. Mr. Whitmore was awarded the prize at the Fontainebleau Competitions in 1922. Jud Landon will give one of his popular open-air talks on the same evening.

A feature of the program Friday evening, August 24, will be the appearance of Adelbert Purga, thirteen-year-old violinist. At the 10:30 o'clock program on the same evening, Pietro Della Ratta will give several numbers on the piano accordion.

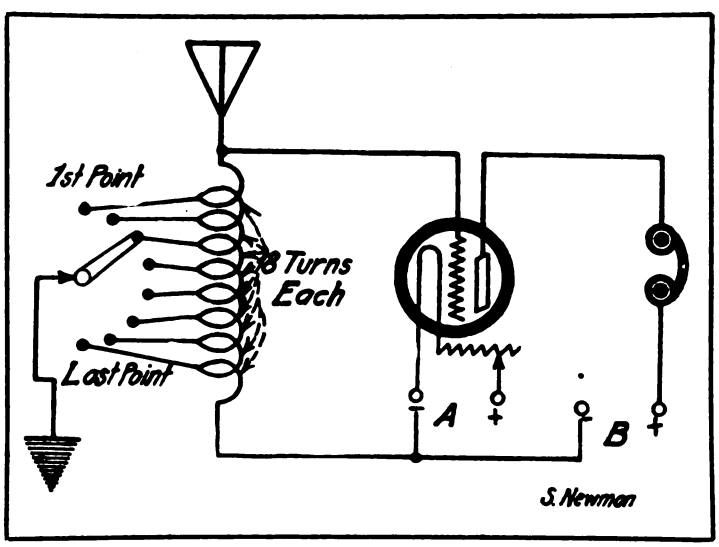
Construction Details of My Midget Set

By Dick Roberts

IN response to many requests, received personally and by RADIO WORLD, for the circuit diagram and constructional details of the midget set described in RADIO WORLD, July 21, 1923, I am furnishing all the necessary details with circuit diagram so that any of the readers of the magazine may, with the aid of the pictures and circuit, build the set.

The coil is bakelite, 2″ in diameter and 2″ high, wound with 80 turns of No. 28 wire. It does not matter much what insulation is used as long as it is safe. Tap every eighth turn, and after winding 56 turns start back on the coil and wind 24 turns more over the first 56, tapping as before. The last turn of wire will be about half way down the coil, and the antenna is connected to the last turn of that second winding.

Great care must be taken if success is wanted to see that there is no chance of a short circuit. The set being built in such small proportions, it necessarily crowds everything and makes it hard to make all the wiring safe, if the utmost care is not taken.



Circuit used in Dick Roberts' midget set. It is the conventional straight audion circuit using a tapped coil for inductance. If care is taken in the construction and wiring, a very neat and capable set will be the result.

As for the particular apparatus employed I used a Signal socket mainly because it was the only one that I could get in town that had a base and terminals that would allow such construction. The rheostat is a Fada with a 2″ dial. Any switch lever will do, but should necessarily have a small arm. The switch points are the ordinary tap points, but the rear extensions are cut short, after they are fastened on by means of the nut. If this is not done, they will protrude and interfere with the placing of the coil. The jack is a Chelten, with part of the insulation cut off to prevent it from hitting the coil. The binding posts are the smallest ones I could get and were purchased at a local Five and Ten Cent store. The panel is a piece of hard rubber taken from an old storage battery jar, although any panel material can be used.

In operating the set it will be found that the right amount of B battery will have to be found according to the particular tube used. With the tube I used (UV200) I found that about 18 volts were correct when the battery was new, moving the tap as the battery ran down. Particular care will have to be taken with the filament current, as it is important in the tuning of the set. Stations that cannot be heard with one adjustment can be brought in simply by varying the filament voltage. I found that stations within 400 miles come in on the third to fifth tap, according, of course, to their wave length. Kansas City, Mo., comes in on the third tap, and St. Louis, Mo. (both the same distance), comes in on the tenth tap. Volume of the signals can be varied by both the switch and the filament.

Too much care cannot be taken in the construction of the set if good results are wanted. I personally took an entire night planning the efficient wiring of the set before I heated the soldering iron, and then wired it up just as I had planned. Due to the fact that the set is small there are plenty of ways of wiring it, but the builder will, if he thinks, find one or two ways that will probably enable him to use an inch or two less wire, and that will increase the efficiency of the receiver.

Paraffine Is Useful

MANY fans do not realize that paraffine is extremely helpful and useful around a radio set. Its use will sometimes improve reception many times.

Instead of shellacing the windings of coils, dip them for a moment in paraffine that is boiling hot, and allow them to drip until all the excess paraffine has been removed and there is just enough to hold the windings firm.

Instead of spaghetti for insulation, especially around a receiver, the use of a roll of tubular tape, such as can be obtained at the five and ten cent stores, and which women use for drawing strings, if dipped into paraffine and left to dry is suitable, and much cheaper.

Radio Broadcasting Station WKAQ San Juan, Porto Rico

By J. Agusty

WKAQ is the radiophone broadcasting station of the Radio Corporation of Porto Rico, affiliated with the International Telephone and Telegraph Corporation of 41 Broad street, New York. It is located in the center of the city of San Juan, Porto Rico, and its geographical position is Latitude North 18°-25′-4″. Longitude West 66°-6′-57″.

The station occupies four rooms—the studio, reception, operating and power rooms. The transmitter is the standard Western Electric 500 watt with two 250 watt oscillators and two 250 watt modulators. There is also a 50 watt speech amplifier. Actual radiation

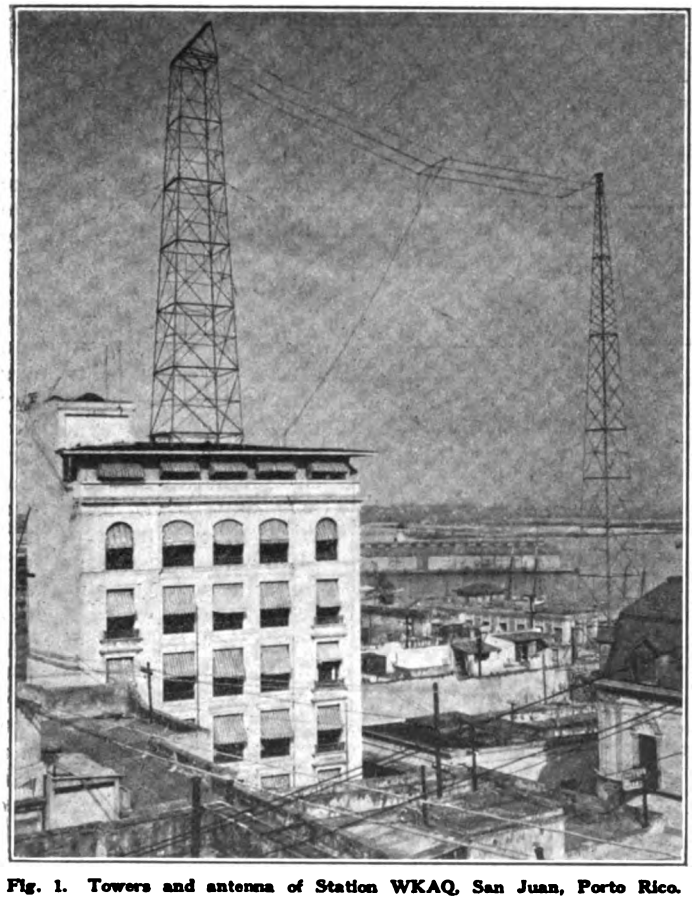

Fig. 1. Towers and antenna of Station WKAQ, San Juan, Porto Rico. The station is owned by the Radio Corporation of Porto Rico and is located on the roof of the telephone building.

on 360 meters is 6¾ amps. The well-known system of modulation is used.

The station is situated on top of the telephone building. On the roof is a steel tower 87 feet high supporting one end of the three-wire antenna that runs 90 feet horizontally to another tower 187 feet above the street level. The lead-in comes from the center, giving a "T" type aerial.

The first broadcasting was done in August, 1922, but the official inauguration was held on December 3, 1922.

The studio of WKAQ, similar to all broadcasting studios, is a room different from all ordinary rooms. Walls and floor are covered with heavy curtains and carpet to deaden echo. In one corner near the ceiling is a red lamp which is in series with one in the reception room and another in the operating room. Under each of these lights there is a framed notice which reads: "When the red light is on, the slightest sound is picked up by the microphone and broadcast. Please keep quiet."

In the operating room are located the transmitter which includes the speech input amplifier with its monitoring horn, the power panel to control the power, the regular transmitter and the receiver. This room is the place for the operator in charge of the station.

The reception room in this station is also the office of the station's manager. Here the artists who take part in the program await the call to the studio.

The power room is apart from the studio to eliminate all possible noises. Here an Ecko motor-generator of three units, supplies the necessary power for the transmitter. There are two sets of Exide batteries to light the filaments of the speech input amplifier and receiver tubes. Also the batteries supplying the plate potential.

WKAQ has been heard in every state of the United States, Canada, West Indies, Mexico, Central America and South America. An interesting thing is that most of the letters received indicate that this station has been heard perfectly clear through the roar of the broadcasters in the United States.

Porto Rico is now an established part of the radio world. It had already joined the mainland by amateur radio telegraphy through the remarkably efficient efforts of the local division of the A. R. R. L. And now just as our sister island Cuba has carried the music and the spoken word of Cuba into our world-wide common property, the ether, so has WKAQ introduced Porto Rico to the broadcast listeners of this hemisphere.

Radio Reports the President's Death

By Carl H. Butman

WASHINGTON, D. C.—For the first time radio played an important part in the dissemination of news of a national character, when President Harding died in San Francisco on August 2. The President's death occurred at 7:30 p. m., Pacific time, and the Associated Press had the story out within five or ten minutes, the report being received at the Washington office of that organization at 10:55 p. m., Eastern standard time, or 25 minutes after President Harding died.

The first intimation the general public had of the President's death, however, was when various newspapers having broadcasting licenses sent out the Associated Press dispatch. Among the first papers to get on the air with this important news was the Memphis *Commercial-Appeal*, whose announcement was the first word Washington listeners-in had of the event.

The news by air that the President had died, resulted in a great number of telephone calls to the newspapers and various offices of the Associated Press throughout the country. As a result of the broadcast announcement, the news of the President's death was generally known from 30 minutes to two hours before the newspapers in the larger cities were out with extras.

Army and Navy to Use Radio in War Games

By Washington R. Service

WASHINGTON, D. C.—Assistant Secretary of the Navy Roosevelt has a unique idea for the use of radio in army and naval war games. He proposes the joint study and solution of a problem involving combat operations, such as an over-seas expedition, by the war colleges of the army and navy simultaneously, every move being radioed to umpires meeting in the War or Navy Departments near their radio central offices.

War games are old, but Colonel Roosevelt's idea is to bring the land and sea postgraduate war schools into a closer relationship during peace times when they have time to work out problems involving both arms. Military and naval forces would be operated theoretically on paper, just as they would co-operate in time of war.

Since the Naval War College is located at Newport, R. I., and the War College of the Army in the Capital, it would be expensive and difficult to bring all the students into one large hall for the joint study of intricate war operations. Therefore, he suggests that the students remain in their respective class rooms, where all facilities such as books and tables of reference, maps, charts, etc., are available, and as fast as orders, plans and movements of troops or ships are made, to radio the action to the board of judges sitting in Washington. The army and navy officers acting as umpires would have two charts in their meeting place and plot every move made by the students at each school.

Upon the completion of the "game," which might require a week or ten days, the umpires would decide which of the schools had solved the problem correctly or to the best advantage and announce the result by radio to the students.

It would not be a contest between the army on one side and the navy on the other, but would involve the handling of both sea and land forces. The naval class would be divided, one handling the Red forces, the other the Blue, while the army school would also fight out the same problem, dividing against itself. Such studies, naval officials believe, would tend to familiarize naval officers with the military end of war problems and army students with the marine side of such conflicts, effecting closer co-operation and understanding of combined national defense.

In One Year Radio Stations in U. S. Increase 1126

By Carl H. Butman

(*Copyright* 1923)

WASHINGTON, D. C.—The end of the fiscal year shows a gain of 1126 radio stations of all kinds in the United States, according to the Department of Commerce figures just compiled. On June 30 there were 21,967 ship and land radio stations, whereas a year ago there was a total of 20,841. The increase represents added interest among amateurs and broadcasters who have taken out station licenses during the past twelve months. Amateur stations increased from 15,504 to 16,570 on June 30, showing a gain of 1,066. Broadcasting stations number 191 more today than a year ago, having increased from 382 last year to 573. On June 30, 1923, the official tabulation was as follows:

	1923
General and restricted amateurs	16,570
Special amateurs	178
Trans-oceanic stations	12
General public service to ships	45
Point to point stations	179
Broadcasting	573
Technical and training	127
Experimental	261
Ship stations, commercial	2,723
Government ship, inc., Navy and Army	1,009
Government land, inc., 24 light ships	290
Total	21,967

Interest in amateur activities is indicated by the following table which shows the gains by districts in the past three fiscal years:

Amateur Radio Stations

Districts	Headquarters	June 1921	June 1922	June 1923
1	Boston	2040	2489	2139
2	New York	1880	2348	2055
3	Baltimore	1325	1857	2005
4	Atlanta	208	341	449
5	New Orleans	418	758	948
6	San Francisco	1136	1756	1957
7	Seattle	504	753	864
8	Detroit	1615	2354	2013
9	Chicago	1683	2848	3340
	Totals	10809	15504	16570

Development of Broadcasting

By S. B. Davis

Assistant Secretary, Department of Commerce

WE meet tonight to welcome the youngest member of the radio family, which is to devote its life to what we now call "broadcasting," an activity so new that the word itself, in its present significance, was unknown only a few years ago. The family has been of rapid growth, but it is not of the mushroom type to flourish but a moment and then perish. We who listen nightly to the messages that entertain and instruct us accept them more or less as a matter of course, without much thought of either their mystery or their novelty; but no prior discovery has ever seized the public mind and sprung so rapidly into general popular use as has radio.

The first license authorizing a station to broadcast was issued in September, 1921, less than two years ago. Tonight, with the entry of this latest station into the field, there are five hundred seventy-three stations in this country authorized to broadcast. Born in the United States, broadcasting has largely retained its Americanism. Foreign countries have adopted its English name into their language. In all the rest of the world there are only sixty-three such stations, and of these, thirty are in Canada, our nearest neighbor. How many people receive their messages no one knows, but in our country alone they are numbered by the million. Never since the first letter was printed from movable type has such a huge stride been taken to make information freely available and to put knowledge and education within the reach of all.

Since the day when the savage sent his messages by signal fires and beating drums man has been striving to conquer distance. He has dotted the earth with his railroads and automobiles and the sea with his ships in his effort towards the more speedy transportation of person and property, and at last for the same purpose he traverses the skies. * * * Radio now supplements the telegraph and telephone; it has become the voice of ships; it bridges uncharted seas, and spans unsurveyed distances on land. It brings the church, the market, public speech, music and instruction into our homes. This most scientific of modern discoveries has become a household factor of common use. The human voice carries with it the elements of personality, force and earnestness, vital to any plea, far more effectively than does the printed word.

Broadcasting conveys the expressed thought of one to the minds of many. It is a unique means to that end, and it is unique again in that, in most instances, whatever future development may be, it now has small direct commercial value. Measured in dollars and cents of profit to the transmitter its worth in most cases is small; measured in terms of service its value cannot be calculated. I doubt if there is in the world another activity involving so great an effort in science and invention and such an immense actual expenditure of money in installation and maintenance, not founded on the expectation of immediate financial profit.

Under existing laws, enacted by the way, some years before broadcasting had been heard of, our government regulates the transmission of radio messages of all kinds. At first devoted largely to the protection of life at sea, that regulation of late has been particularly

A Little Wonder Portable Set

By Byrt C. Caldwell

THIS wonderful little set is easily constructed and gives results equal, and usually better, than full-sized sets. This is due to its extreme compactness. The U. V. 199 and C. 299 make this set possible.

The first requirement is the containing box. It should be made from quarter-inch stock, and should be about 3"x5"x7" outside dimensions. All the instruments and binding posts are mounted on this, and the heads of the screws should be countersunk and the holes filled up with filler. It should then be sandpapered, varnished, and polished. Or it may be finished by covering with black velvet. Either way makes a beautiful set.

The inductance is a 50 or 75 turn spider web coil, which can easily be constructed from instructions to be found elsewhere. It is fastened to the bottom of the box. The condenser is of the book type, as compactness is required in this set. It is placed on top of the inductance. The shaft projects through the side of the box, and a small knob is used instead of a dial.

The tube is mounted on the side of the box, and the variable grid leak and condenser, the rheostat, and the "A" battery, which is a 4½ volt flashlight battery, are placed as shown.

The "B" battery consists of eight 3-volt flashlight batteries connected in series, and fastened to the cover of the box as shown, by means of thin strips of brass. This battery is connected to the rest of the set by means of flexible wire, so that it is not broken when the box is opened. When mounting these, be careful

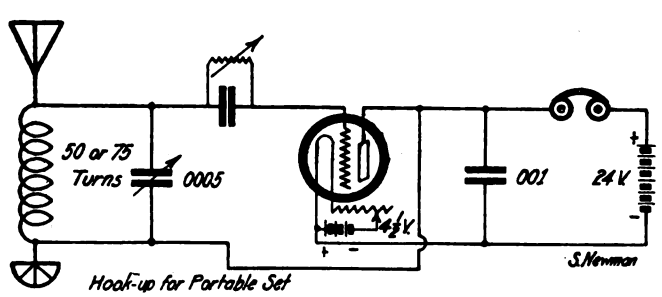

Fig. 1. Diagram of circuit used in the little portable set described herewith. It is the ultra-audion circuit which is very selective and easy to control.

that they do not touch the edges of the box, or any of the instruments when the box is closed.

In this set, a counterpoise is used in place of a ground, as being more efficient and more convenient. Two 100 foot lengths of No. 22 enameled wire are wound, each one on a spool, and placed in the box as shown. Heavy elastics are used as insulators. The wire specified should be insulated, so that in case the antenna touches a tree or some other conductor when it is hurriedly strung up, there will be no loss of energy.

The phones are to be connected to the two binding posts shown. They must be carried outside of the set, unless a pair of the very small sized phones which are seen on the market are used, in which case, plenty of room on top of the movable condenser plate and the rheostat may be found for the phones.

When the set is to be used, unwind the spools of wire, string one as high as possible, and connect it to the upper binding post in the diagram. Suspend the other a few feet from the ground, and connect it to the other post. Then light the filament and tune with the condenser in the same manner as you tune your large set, provided, of course, that you tune this properly.

The same general rules for wiring all sets apply in this set as well. The only difference is that there is a better opportunity in this set for short straight leads than in a large set where the instruments are spread all over a panel. The wiring is not shown in the

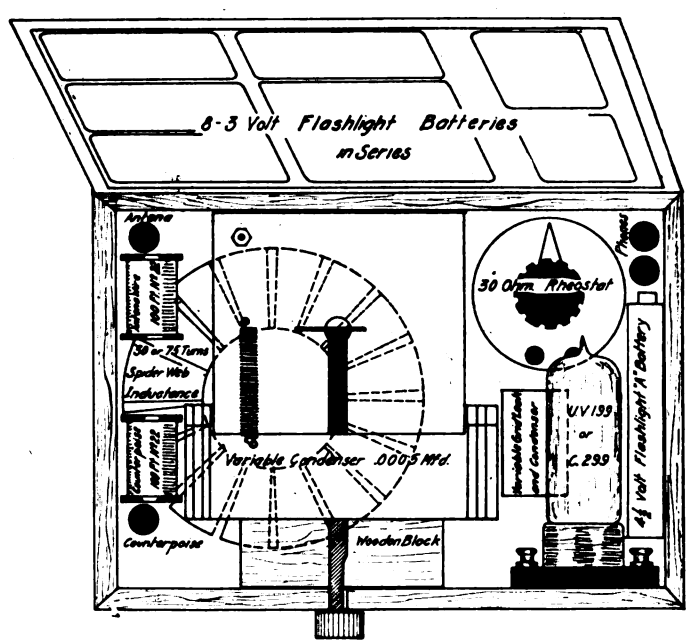

Fig. 2. Layout suggested for the receiver described. The batteries can be placed in the cover of the box and connections made with flexible wire.

diagram, as this would probably lead to confusion. The hook-up given is the usual single circuit regenerative. The set is easily wired from this hook-up.

This set is one of the most easily constructed you can imagine, and it gives wonderfully consistent results over distances of a thousand miles and more. The new peanut tubes make it possible to construct this beautiful little completely self-contained set which fits into a pocket, and yet gives results equal to the most elaborate of home sets.

Do You Dust It?

SUMMER time is lazy time. You are naturally lax in all things, but you should not forget to use the dust cloth and duster on your set. If dust collects, it will short the set and cause innumerable little by-paths for the minute currents, and your receiving range will be cut down enormously. When working inside the set it is best to blow the dust out with a rubber tube, as then you will not chance breaking wires.

Painter, Attention!

THERE are many amateur builders who, after they have constructed a set, will give the cabinet and base a healthy coat of nice looking finish. Nine times out of ten the paint contains some lead, zinc or other metallic oxide which will form a nice leak for the set. Clear varnish, or shellac, is best for this purpose—or alcohol stain and wax polish for the finish.

Invisible Singers Entertain Boy Scouts by Radio at Camp Glen Gray

By Gilbert Bonnell

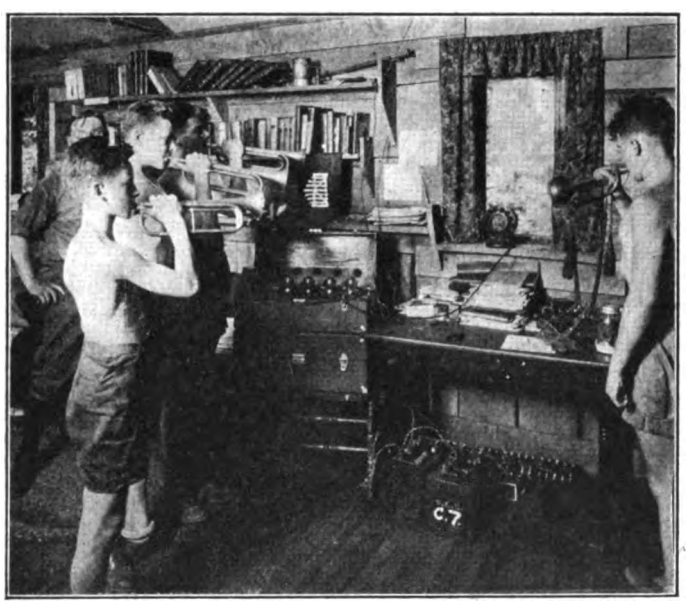
RADIO is the great boon of boys, particularly those who are members of the world's largest boys' organization, the Boy Scouts.

Boys are ardent radio fans; they find rare enjoyment and entertainment in the ether, they sport with its waves as do skillful swimmers in the sea.

Radio has done more than anything else to relegate lurid dime novels to the limbo of discarded things, for its popularity with young America has brought into being the excellent publications that boys read avidly.

Radio justly deserves the important place it occupies in Boy Scout camps throughout the length and breadth of the land.

A notable example of how radio plays a leading part



(C. Western Electric Co.)

Bugle call at Camp Glen Gray, the Boy Scout Camp at Oakland, N. J. A Western Electric Public Address System amplifies the bugle calls so that they are heard all over the camp. In the picture are Gordon Gavan, of Montclair; Douglas Pease, of Upper Montclair, and Edw. Veleau, of Montclair, N. J.

in the program of the camp day is at Camp Glen Gray, the Montclair Council Camp in Bergen County, New Jersey.

There in the Ramapo Hills where the red man's watchfires once gleamed is the campfire of the first Boy Scout troop organized in the United States.

Around that campfire the Boy Scouts of Montclair, Glen Ridge and Nutley, nightly gather and listen to the voices of invisible singers miles away across the mountains. As a matter of fact the boys could as easily hear the singing in any other part of the camp for radio programs are made clearly and distinctly audible over all of Lake Vreeland and the full length and breadth of the camp situated on the lake shore.

This is accomplished by means of the Western Electric No. 3 public address system which P. M. Rainey and R. M. Hatfield, of Montclair, brought to the camp where their sons are sojourning.

This system, while compact, is capable of amplifying radio reception some several thousands of times without distortion. It is a vacuum tube amplifier similar to, but smaller than the one which made President Harding's inaugural speech audible to the largest assemblage that ever heard any inaugural. It is mounted in a hardwood cabinet containing an insulating panel upon which are mounted four vacuum tubes and the necessary transformers, resistances, condensers, switches, etc., for three stages of amplification.

The public address system may be used to amplify radio received programs or, when connected with the microphone, it may be used to amplify local speeches, vocal and instrumental music.

The microphone which picks up the voice or music is the same as that used in the larger public address systems.

A group of horns is mounted on the balcony of Mothercroft, the recreation hall at Camp Glen Gray. These horns are exactly the same as those used in the Yankee Stadium when a public address system made the announcements at the Willard-Johnson fight audible to 74,000 fight fans. The horns uniformly and distinctly carry the amplified voice or music over the area it is desired to cover at the camp.

Camp Glen Gray was established in 1917 by "Uncle" Frank F. Gray, who organized what is the oldest Boy Scout troop in this country, Troop 4.

The camp is located on the shore of a lake in the Ramapo hills, about four miles from Oakland, New Jersey. This section of the country was deserted in '49 by the settlers who went to California in the gold rush. Today it is a veritable forest primeval.

The camp consists of a spacious mess hall and kitchen, a large recreation hall, the hospital, the director's cabin, a store and long streets of tents. Each boy has a tent all for himself.

The camp is governed by the boys. They have their own mayor and ward leaders. "Co-operative discipline" is a feature of the boys' form of government. The boys can make an all day hike on their own land for the Montclair Council Camp's tract covers approximately 500 acres.

The Cannon Ball Road—so-called because the Tories in yesteryears hauled cannon balls over it from Pompton to Westpoint—passes through the property. Today the ruts worn by the wheels of the Tories' carts are obliterated; the old road is but a trail leading to the lookout from which, on a clear night, the lights of Manhattan Beach can be easily seen.

The camp day at Glen Gray begins promptly at 7:30 o'clock in the morning when the bugle's peremptory notes are sounded. Now that the Western Electric amplifier is available the buglers "boost up the range of their lung power" by using the apparatus to amplify the calls.

The boys turn out at the bugle call, stand at attention while the flag is hauled aloft. Then they go through setting up exercises that start their bodies tingling. After the calisthenics they may take a dip in the lake or retire to their tents until breakfast. Mess over, squads are assigned to various duties.

Frequently "Uncle" plays his piccolo before reveille. This music is also clarioned by the public address system and flung far into the forest surrounding the director's rustic cabin.

(Concluded on next page)

Digitized by Google

(*Concluded from preceding page*)

At 11:00 the boys may begin to indulge their aquatic propensities and for three-quarters of an hour swim and dive in the crystal clear waters of Lake Vreeland. Mess at noon is followed by recreation periods, including the day's second swimming period at four o'clock.

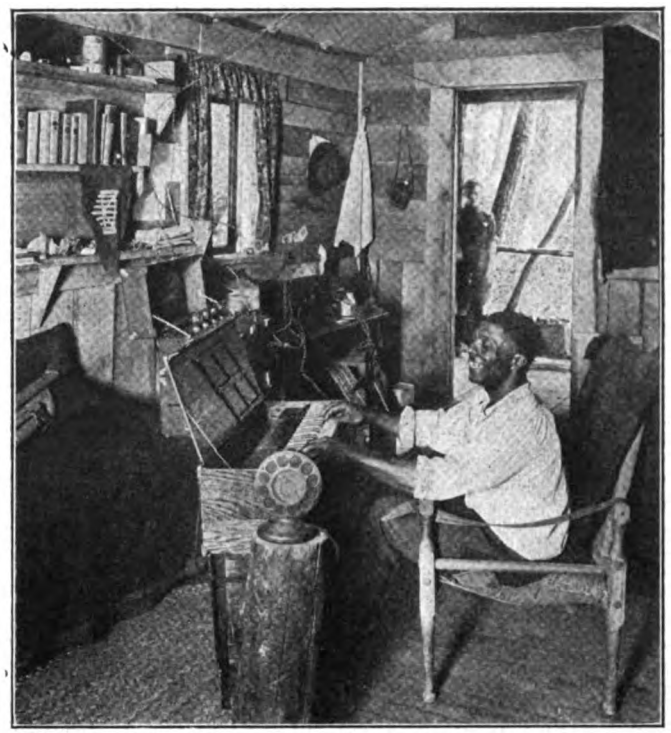
Sometimes Dave, the colored cook, gives the boys a musical treat. He is a clever manipulator of the stops and keyboard of a portable organ and he possesses a good singing voice as well. His organ recitals and renditions of songs of the sunny Southland are enjoyed by the boys equally as much as are his clever culinary concoctions. Nowadays Dave "does his stuff" with the microphone of the public address system close by. He smilingly says, "Ah knows everybody'll sure enough hear me when ah's got that in front."

At retreat (5:30) the flag is lowered with appropriate ceremonies. At this time new details for the following day are appointed. After evening mess the boys play games or roam about the camp streets until dusk. Then they assemble at the campfire. Here again radio made audible to all the assemblage by the sound amplifier, is used to entertain the boys.

One of the treasured traditions of the camp is that the campfire is kept burning from the hour the first contingent comes to camp until the last departs. A log is pulled out of the final fire before it is extinguished and this charred chunk is kept until it is used the following year to kindle the new fire.

At 9:00 taps is sounded. After taps "Uncle" plays several classical selections on the phonograph. This music, too, is amplified just as radio lectures are during the day. Religious services are held every Sunday night at the campfire. Last Sunday morning the sermon broadcast from St. Thomas' Church, New York City, was amplified.

The scouts at Camp Glen Gray are ever working to win merit badges in the various subjects for which badges are awarded. Some of the most important subjects are radio, life saving, first aid, sanitation, forestry, zoology and trailing.



(C. Western Electric Co.)

Dave Simmons, the chef, regales the Boy Scouts at Camp Glen Gray, Oakland, N. J., with organ recitals and song renditions which the boys claim are as good as his culinary concoctions. A Western Electric Public Address System carries Dave's efforts to all parts of the camp.

How to Cure the Squeals

By E. L. Kemp

I WOULD like to tell the "homebuilders" something which may put them wise to handling some of their "weak stations."

I am a "homebuilder," too, and owe my success to RADIO WORLD, to which I am a subscriber. In nearly every issue some one tells us how to tune our sets, but in every such case something is always left to be guessed at or worked out by us. As an instance: We are told that the best point at which to adjust our grid leaks for maximum reception is at the point where the scratchy scream is highest. They state in concluding that this adjustment is now final for the tube used and should be left there.

Ah! They are right, *so long as our B battery current remains the same!* But—if you use a variable B battery and step it around on different stations, say from 22½ to 45 volts, then I find that O. M. Grid Leak cries out.

You don't have to lose your station when making adjustments if you follow the plan that I have found out works best. Suppose you have a DX station and it is very weak. You step up your B battery and adjust your other controls, but the music or talk is still weak, if it does not fade out in a bunch of squawks.

Try this: See what your antenna condenser reads and then turn it completely to zero. Adjust your grid leak to that high point and then leave it, after you have gotten your signals in loud enough. Then turn your condenser back to its former position and note the increased strength of the signals. All the other controls need not be touched.

I hope that I have helped some of my fellow "homebuilders."

Mix Radios His Mother from the Arctic

WATERBURY, Conn.—Ten minutes was the record time consumed for the sending of a radio message from Donald B. MacMillan's Arctic-bound schooner "Bowdoin" to Bristol, Conn., via a local amateur station, and the relaying of a reply back to the ship which is northeast of Labrador.

The prophecy that the radio installation on the "Bowdoin" could be utilized by members of the crew to communicate constantly with friends and relatives at home has proved true and has become a fact.

The message in question was a personal greeting from Donald H. Mix, radio operator with the exploration party, to his mother in Bristol. Communication was established with WNP, the Bowdoin's radio shortly after midnight by Allen C. Lawson here, who immediately called Mrs. Mix by telephone. The reply was soon on its way north and Lawson heard Mix acknowledge its receipt with thanks.

The Radio Woman

IN answer to a frantic appeal for more or less expert assistance, I called on a little friend of mine recently, who earns her living by frolicking now and then for the edification of the T. B. M. on one of the well-known vaudeville circuits. She had a radio set, newly purchased and hooked up, and thereby hangs this tale.

"I bought this thing-um-a-bob yesterday," she snarled sweetly, "because it seemed like a good chance to get my picture in one of these radio magazines, and as my press agent says, 'Publicity is publicity.' But now," she wailed plaintively, "I can't get the dawgone do-hicky to do its stuff. What's the idea of the thing? What do you turn, and how many times do you turn it, and in what direction, and how much, and why? Do you see this funny little knob? Well, I've turned it and twisted it, and swore at it softly, and in loud, vulgar accents, and I've coaxed it with soothing words, and have done everything else but kick it out of the window, which will be my next move, and yet I can't make the set do anything more than just squeal and moan and sigh as though it were two cats instead of one. What do you know about these things?" she queried belligerently, as though challenging my advice before it was offered. "The man who put the darned thing here said that it was in perfect condition and he got something or other on it for me, but as soon as he left everything went away from here—including my patience. What's the matter with it? I haven't moved a thing, except this funny little wire, which I thought would look much cuter if it were strung over on this side of the table instead of under it."

Well, talk about hysterics. I never was nearer to them in my whole life. The little dear had very deftly removed the antenna lead from the set and connected it on to one of the B battery leads. No wonder she was getting squeals and howls. I connected it to the right post and under sentence of death forbade her touching any wire until she had read the instruction book thoroughly and undersood just what was what. "Why, you might blow up your tubes," I said, "and they would scatter glass in your face and ruin your theatrical career," thinking that a good scare would teach her to use more care.

"Oh, take it away from here. I thought it was perfectly safe. I won't have the blame thing in the house if it is going to behave like a gasoline tank with a lighted match." And then I had to take an hour and explain that there was no danger, but that I simply wanted to throw a scare into her to make her remember not to fool and fiddle with the little "do-hickies" on the back of the cabinet.

After I got it working nicely and had shown her how to "get the blamed thing to work," she thanked me and told me that anytime that I was down in the "bright light" section of town to run in and she would show me the "ins and outs" of the theatre backstage.

RADIO PRIMER

THE ELECTRONIC THEORY—The electronic theory is frequently quoted in regard to the operation characteristics of vacuum tubes. A discussion of the theory in a semi-popular manner would clear up in the minds of amateurs in the science a very puzzling situation and in a manner make clear what happens on the inside of a tube when the filament is lit.

An electron to begin with is the smallest known particle of negative electricity. According to Webster an electron is defined as follows: One of those particles having about one-thousandth the mass of a hydrogen atom, which is projected from the cathode of a vacuum tube as the cathode rays, and from radioactive substances as the beta rays.

The electron is therefore found to be an electric carrier that has a negative charge. It was discovered by Edison some years ago that a filament enclosed in a vacuum threw off negatively charged particles. These particles were found to emanate in all directions from a heated filament, with terrific velocity, the amount given off being dependent upon the heat of the filament.

Applying the same principle to the vacuum tube, it can be seen that the action occurring within the tube is somewhat as follows: The filament is heated, giving off an innumerable quantity of these negative charges. The plate of the tube naturally has a positive charge and as unlikes attract, the negative electrons bombard the plate.

The grid of the tube, which is placed between the plate and the filament periodically changes from negative to positive polarity, according to the condition existing in the grid circuit at the time. When it is positive, it closes all paths to the plate, much like a gate closes water off when the dam is low, allowing an additional charge to gather behind it, which return to their source. Then as the change takes place, the negative electrons again bombard the plate, being helped by a negative grid, which allows a stream of electrons to cross, carrying from the grid to the plate, which current actuates the phones, they being in the plate or high tension side of the circuit.

(*Concluded from page* 6)

directed to broadcasting, and has been made necessary by the crowding of the hitherto free and unoccupied air, which we call interference. By the allocation of wave lengths, the inspection of transmitting instruments and the attempt to induce better methods both mechanical and personnel, it is trying to minimize troubles so far as possible in the present state of the art.

Avoiding actual control and management, it has left the radio field free to individual research and personal initiative, adopting in this respect a policy unknown to most foreign countries where we frequently find direct management, close control, many restrictions and a strict system of taxes or fees imposed upon all stations and instruments whether for transmitting or receiving. We have chosen rather the minimum of intervention consistent with due regulation, coupled with full assistance in the working out of scientific problems. The government has enjoyed invaluable assistance from the persons directly interested, those who transmit and those who receive, and it appreciates the aid given it through the public conferences held under the auspices of the Secretary of Commerce, and the spirit with which all have joined in trying to solve common difficulties.

Rather than attempt to prophesy tonight, let us welcome this new station, a sturdy youngster, as it needs to be to hold its own with its broadcasting brethren; let us congratulate the men behind it upon the courage, enterprise and genius which have made it possible, and dedicate this latest example of modern magic to the dissemination of knowledge, to the increase of culture, to spiritual development, and to the spread of entertainment and happiness among the countless thousands who will hear its voice.

A Card File for DX Reports

By Charles F. Filstead

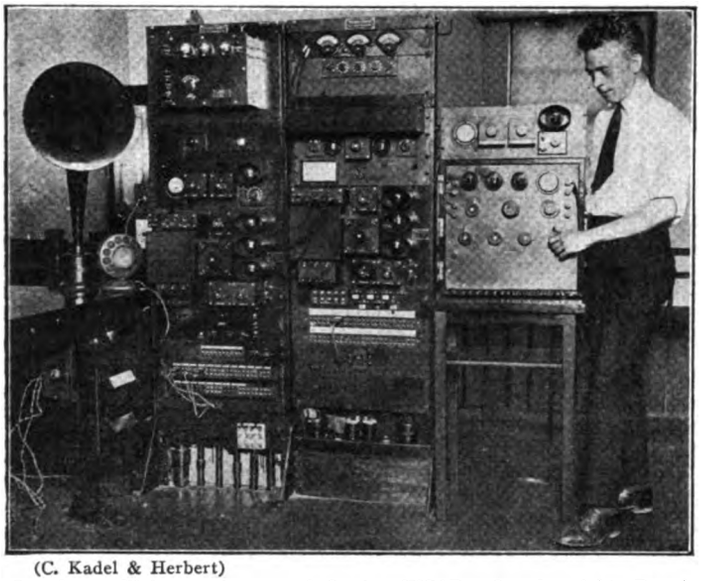
AMATEURS, as a rule, rate the efficiency of their transmitters by the number and distance of the cards they receive reporting their signals. They are perfectly right: there is no better way of determining the relative "getting-out" qualities of two individual transmitters than by comparing the number of distant stations that they have worked and who have reported them. Some amateurs even go so far as to tack up on the wall all the cards they receive, thus making the interior of their radio-room look very much like a futuristic artist's conception of the setting sun. To get away from this gaudy, patch-work effect, and at the same time have my cards where visitors could see them if they so desired, I arranged them alphabetically and according to districts in the form of a regular card catalog. The boxes used to hold the cards in standard card files are too small to hold post cards, so a special box must be constructed. This box may be made of almost any kind of wood, although quarter-inch thick oak or walnut, when properly stained, will probably make the best looking job. The inside dimensions of the box should be three inches high, eight inches long, and five and three-quarter inches wide. A box of this size will hold about 650 standard post cards together with the necessary index cards. The box can be held together with small nails or flat-head wood screws, and when finished, it can be stained and shellaced and, if desired, varnished.

There should be nine index cards, one for each district, and each one marked with a number from one to nine. In addition, there should be an index card marked "Foreign" and one marked "Canadian." If the builder has a great many Canadian reports, it would be best to have them also divided up into districts by index cards. All cards received from outside the United States—including boats at sea—should be grouped under "Foreign." The cards from each district should be placed in front of the index card bearing the number corresponding to that district. To make the finding of a card easy, it is well to arrange all the cards in each district alphabetically. If the amateur still wishes to adorn the wall, he can choose the best looking card from each district he has in Canada and the United States, and also one from each of his foreign countries, and tack them on the wall.

If he so wishes, the broadcast listener may start a "Stations Heard" file, in which he can place a card from each broadcasting station he hears. A good stack of cards from broadcasting stations acknowledging reports of hearing them would be a very good thing to rate the range of a receiving set by.

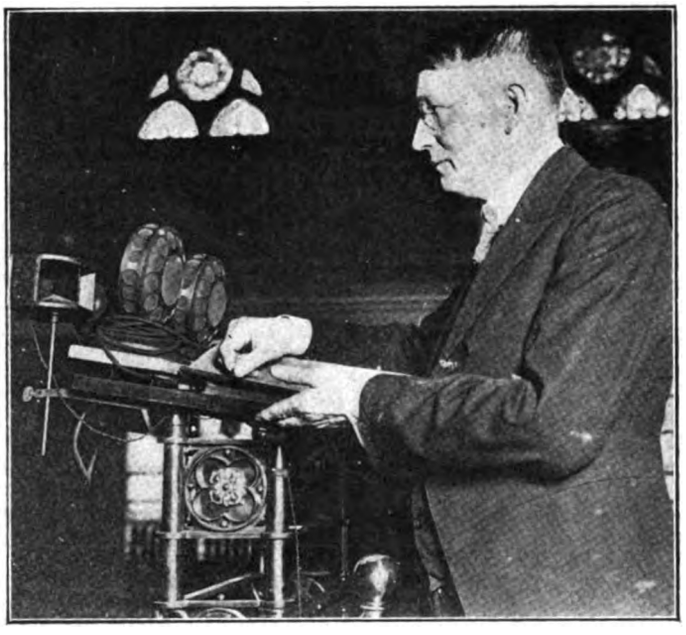
A large map should be used in conjunction with the card file herein described to show the location of the stations from which cards have been received. A map-tack should be put up for every broadcasting station you hear over a certain distance. The tacks representing the stations you have heard but once can be of one color, and the rest of a different color. These colored map-tacks can be bought at any stationery store. The map should have a cardboard backing heavy enough to hold the tacks and also to prevent them from marring the wall. Amateurs should have one color tack for the stations they have worked and another color tack for the stations that have heard them. To save tacks, it is well to mark stations only over a certain distance.

Harding Memorial Service Broadcast From Station WCAP



(C. Kadel & Herbert)

Speech amplifying equipment of Station WCAP. On the right, Dr. A. Freeman Anderson, who conducted the Harding memorial service at the late President's church in Washington, D. C.



It is estimated that over 1,500,000 radio listeners heard the memorial services held last week in Calvary Baptist Church, Washington, D. C. A close friend of the late President, Dr. A. Freeman Anderson, pastor of the church, delivered the sermon, which was broadcast through Stations WCAP, Washington, D. C., and WEAF, New York City. The services were relayed over special land lines from Washington and rebroadcast through the New York City station. Over half the United States was thus enabled to hear the services which otherwise only a few hundred would have been able to hear. Thousands of people journeyed from all over the country to be present at the funeral services of our late President, but those who could not were recompensed in the fact that they were present in spirit and heard the services as well as those who traveled.

Keeping Down the Circuit Losses

By C. White, Consulting Engineer

THERE is nothing more important in building a radio outfit than the amount of losses in the wiring and the parts of the circuit. The best circuit ever devised will amount to nothing if care is not taken to see that excessive losses are avoided. Still if you should look in the back of some home-made sets and see the wiring behind the panel you would readily agree that the losses must be very high. It is a great regret perhaps that the regenerative receiver works when it is poorly constructed, thus allowing the careless constructor to get away without putting together a good job. A reflex circuit is not so gracious and will not function unless built properly, and this has been the reason why so many do not work at first.

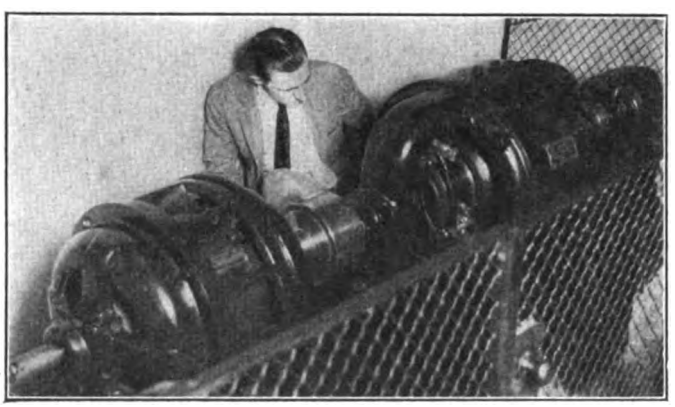
In building your set, first select good standard apparatus that is built right, regardless of the price, although cheap apparatus is not the same as inexpensive apparatus. The condenser, of course, can not be readily built in the home, hence care will have to be exercised in purchasing one. The plates of a good condenser should be of reasonably heavy gauge metal, evenly spaced, having the movable plates well insulated from the fixed plates. No iron or steel parts should be used in the construction. I always recommend that a condenser be mounted in a metal can, although it is to be used in back of a panel. This means that dirt will be kept out of the plates. You can not imagine just how much dirt can collect between the plates of a condenser, especially with those sets which are mounted on panels and have no cabinet. This dirt forms a rather good by-path for the radio-frequency currents and cuts down the effectiveness of the condenser to such an extent that sharp tuning will be impossible. A laboratory test was made on a condenser when new and another test after the condenser was allowed to sit out in the dust and dirt of the room for several weeks. The difference was most apparent.

The coils in the set are another source of losses. A coil should be wound on good insulating tubing, otherwise high losses are incurred. An ideal coil would be one that is wound with no insulating material, but this is mechanically impossible since the coil must be supported. Certain manufacturers of variometers and variocouplers have made use of this when winding their coils. Recently I made a frame just like the frame of a squirrel cage, or rotary rat cage. This form was made of good insulating material but only enough was used to support the coil. Then I wound No. 22 wire in and out of the rods in a manner resembling a basket weave, and, at the same time I kept the wires well spaced. The fact that the wires were kept well spaced and wound in a basket weave reduced the amount of distributed capacity, which meant sharper tuning and clearer signals; and the fact that as little insulating material as possible was used meant that the signal would be loud since the losses were low. If you are in an experimental frame of mind try the thing out and you will realize the difference it makes.

All connections should be made with bus bar wire, insulated with spaghetti tubing, and well soldered. If you use the type of solder wire that has an acid core take especial care to see that the acid does not spatter on to the panel and other parts of the set. This will cause howling and high losses, since the acid forms a good conducting path. The best way to avoid this is to put the solder on the iron first and then apply to the part to be soldered. A bad method is to place the iron, the solder wire and the part together, which will always result in the spatter of the acid on to other parts of the set. If you use resin flux solder be sure not to get resin all over the apparatus used for a similar reason. Keep all wires as short as possible and yet retain a neat wiring appearance. The latter means a lot when you are endeavoring to trace out trouble or to make some change in the connections. Mistakes are not so liable when everything is kept clean and clear, just the same as in bookkeeping. Blow dirt and dust out of your set when you have finished wiring. A little lump of solder or dirt can cause a lot of trouble.

Shielding is always advisable, but, it can like anything else, be carried to excess. I have seen sets that have entirely too much shielding which detracts from signal strength, since it always causes losses. If you can, do without shielding. This is the reason some manufacturers do as little shielding as possible, just placing a little grounded copper foil in the vicinity of a condenser or variometer. All the rules given in this article seem obvious, but you would be surprised to know that 80 per cent. of the troubles my friends have had because signals did not come through as loud as they should was to be found in one of the rules which they have disregarded in constructing their receiver . The old saying is "Haste makes waste," and it certainly is true with the amateur who tries to build his receiver in a minute.

Station WJAZ Has 10kw Generator



(C. Underwood & Underwood)

The Zenith Edgewater Beach Station WJAZ at Chicago includes in its plant a 4,000-volt motor-generator illustrated above. It is this station which is expected to pick up messages from Capt. Donald MacMillan's arctic exploration vessel "Bowdoin," now far north of Labrador.

Do You Realize It?

IT is always a good plan to find out what wire you are crossing or going under when erecting your antenna. It only takes a few hours to make all the inquiries and look around, and you will not be taking a chance of getting killed or injured. Many a man has lost his life or been injured by running wires across high tension or power lines, and having them cross during a high wind or storm.

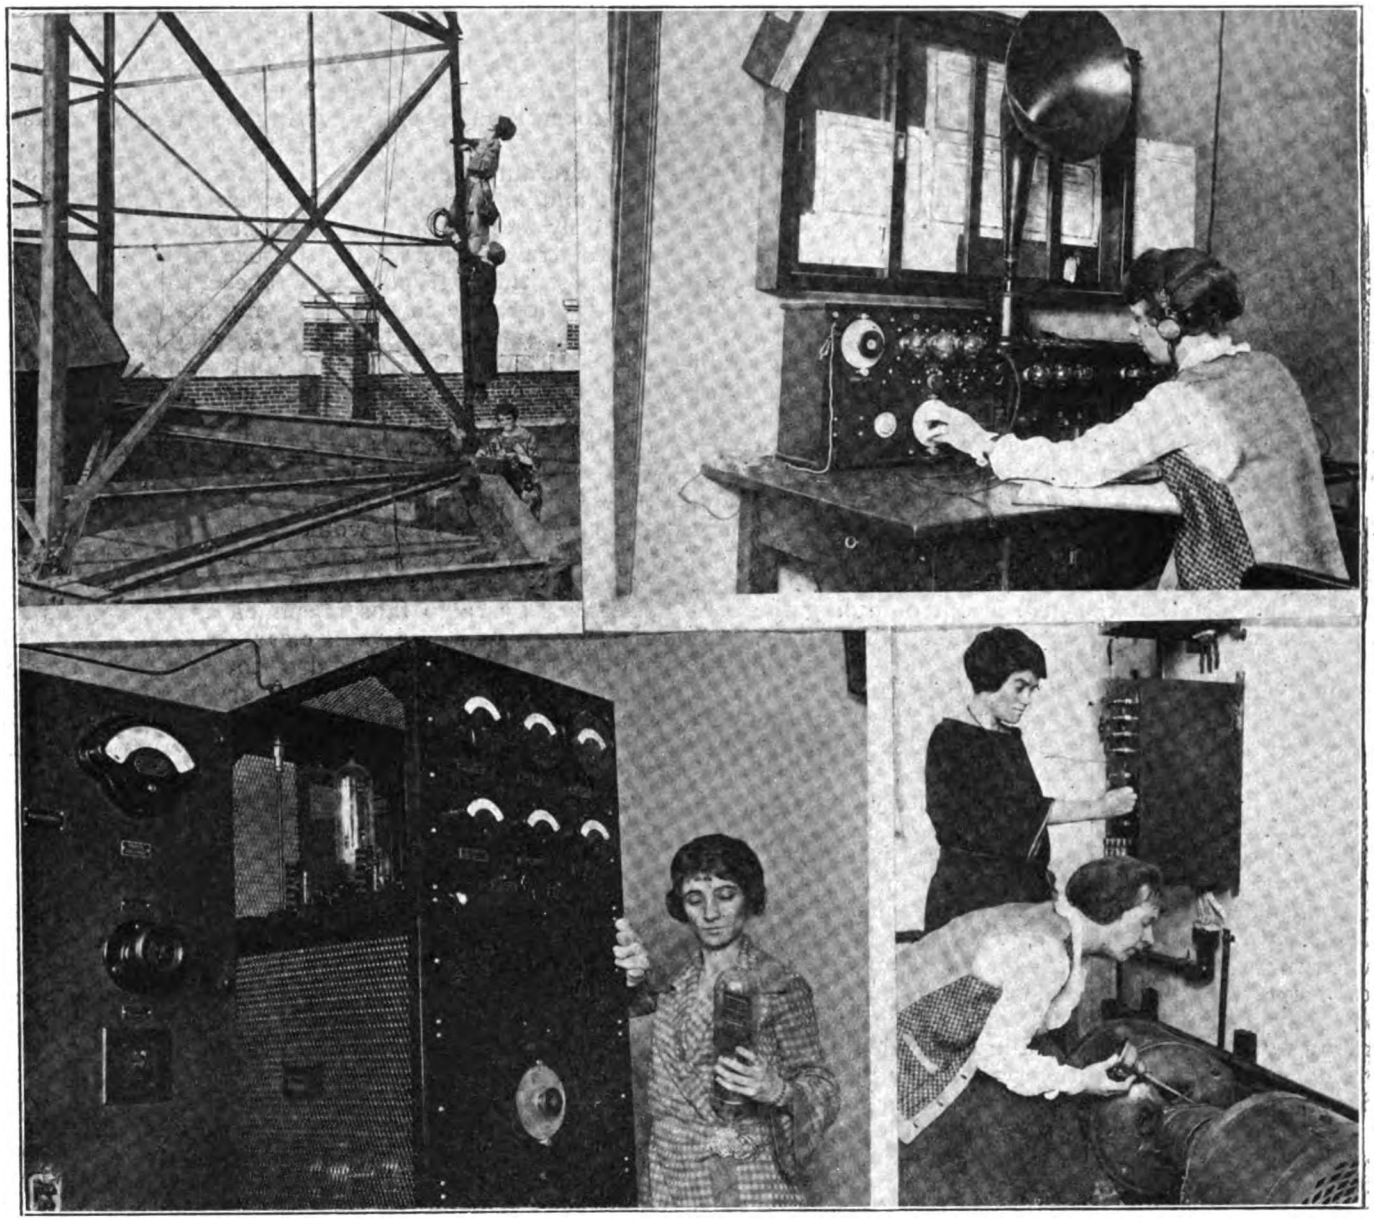
Women Operate a Broadcasting Station



(C. Kadel and Herbert)

For the first time in the history of broadcasting women entirely replaced men temporarily in the operation of a station. Station WEAF, of the American Telephone and Telegraph Company, New York City, was run recently by girls recruited from the regular forces. The upper left hand picture shows Miss Alice Hunt and Miss Elsie Schneeweiss hunting for a leaky insulator up the tall steel mast, while Natalie Connor is checking the wave length from below. Directly next to this picture is Miss Schneeweiss supervising the transmission and keeping a lookout for SOS calls on commercial ship wave lengths. Below is Miss Alice Hunt standing next to the transmitter examining a 250-watt tube. On the lower right is seen Miss Elsie L. Schneeweiss and Miss Natalie Conner oiling the generators and checking up before putting them into service for the day's broadcasting work. Now, who said "A man's a man for a' o' that." It seems that when they get right down to it the so-called weaker sex can give just as good broadcasting service as any man ever did.

Cures for Distortion of Radio Signals

By R. L. Dougherty

MANY operators of receivers, especially the single circuit type, are troubled with the distortion of signals. This makes itself noticeable in mushy signals and indistinguishable speech and music. In extreme cases it is only noticed in the pronounced overtones or undertones, the middle tones being clear.

There are many causes of distored signals and a discussion of them and their control will no doubt be of benefit to the average fan not well versed in the extreme technical properties of his receiver.

The most common cause of distortion lies in supplying the filament with too much current. This causes the tube to oscillate violently, causing what is known as "beats." It is noticed when the set is slightly detuned from a station by a pronounced howl. Of course, the remedy for it is to turn down the rheostat until the signals can be heard clear. To test whether you are getting the proper filament voltage, it is only necessary to detune your receiver on either side of the peak, and if quiet but much lessened signals are heard, your filament voltage is correct. In the reception of distant signals an operator will often deem it necessary

(*Concluded on next page*)

Digitized by Google

(*Concluded from preceding page*)

to tune for the station by this "beat" method, but after the station is once located, the filament should be turned down. In single circuits this slight decrease of filament current will ofttimes cause the signals to come in much louder than when the receiver is oscillating violently. With the dry cell tubes it is very hard to control the tube to such action, so a vernier control for the rheostat is advisable, as you will then be able to make the tube work just before it "spills" and starts to oscillate.

Another cause of distorted signals is an improper grid leak. The grid of the tube playing the active part it does in the reception of signals, must have the correct amount of capacity and leak in the circuit. If too little grid leak resistance is introduced, it will carry off an excessive amount of the minute energy, and the signals will be mushy or weak. Sometimes this condition makes itself known by a constant clicking, which will increase as the capacity is reduced, or decrease as the capacity is increased, and will finally disappear and the tube will have a hollow sound. This is the proper capacity for correct operation. If too much grid leak capacity is introduced the signals will be distorted due to the fact that the grid is not obtaining the correct amount of negative electrons through it, and therefore is overcharged and cannot release quick enough for proper operation. When this condition is present, a thick muffly choked signal will be noticed, and the tube will not show a tendency to oscillate freely when the set is tuned. Reduce the capacity to the point where the speech is absolutely clear and undistorted.

Too much capacity in the grid circuit is another cause of distortion. This is noted as a spasmodic clearing of signals whenever the grid circuit is touched with the hand, and a pronounced body capacity effect in the set when tuning. Too little capacity will cause the signals to be extremely sharp toned in quality, the speech resembling a man with an unpleasant voice with a cold, trying to make himself heard in a crowded hall. Tubes are designed for use with certain capacities in the grid circuit, and if the correct capacity does not seem to produce results, a three-plate variable condenser in parallel with the fixed condenser will soon clear it up if too little capacity is noted, and a smaller fixed condenser in the circuit instead of the one used will clear it up if too much capacity is noted.

Excessive B battery voltage is ofttimes a cause of distortion of signals. Radio fans have found out that if the B battery voltage in a circuit is increased, the volume will increase in a like manner. But they do not take into consideration that the smaller tubes can be "overloaded." In the detector tube, especially if it is one of the dry cell type, a certain voltage is specified by the manufacturer. Fans have found out that they cannot damage their tubes if more than the specified amount is placed in the circuit and they accordingly use a greater voltage than the tube can stand. If distortion is noticed and you are using more than the specified amount of current in the plate circuit you can easily determine by shifting the voltage whether this is the cause of the distortion. It sometimes is best to even use less than the specified amount, if clear signals are desired.

Another cause of distortion in radio sets is noticed when too many sets of phones of different types are connected in the circuit. This is because the phones do not all have the same resistance characteristics, and one pair is not functioning properly. If one pair rattles when more than a single set of phones are in the circuit the entire set of phones connected in the circuit will rattle. Test them out separately and discard the set that is causing the disturbance. In the same manner distortion is ofttimes caused by not having enough resistance in the phone circuit. Frequently a set will bring in much clearer signals when two sets of phones are connected in series than when the two are connected in the circuit in parallel. The test for this, of course, lies in connecting the two sets of phones in the correct manner, by testing out which works the best.

Where amplifiers are used, distortion is very noticeable, and is sometimes almost impossible to correct. The only method of overcoming it lies in the use of the proper transformers, and the use of power tubes as amplifier tubes if possible. These tubes, strange to say, will operate in an amplifying set with wonderful clearness, all other things being equal, and will stand excessive plate current without causing distortion. For instance, the popular five watt tubes can be operated with 190 volts on the plate and sometimes even up to 350 without very noticeable distortion of signals. Were this attempted with the regulation amplifier tubes it is probable that the distortion would be so great that the signals would become a jumble of horrible noises, which would not resemble the voice at all.

Lately there has been quite a bit of trouble experienced by radio fans inasmuch as the signals from one station will be crystal clear, and the signals from another will be mushy and distorted. If you receive signals from the greater number of stations clearly, and a single station is mushy, you do not need to look to your receiver for trouble as it is the modulation of the transmitting station that is at fault.

Probably the most common form of distorted signals results from "forcing" your regenerative sets. This is caused by too close coupling when operating the set just below the "spill over" point. Regeneration can be carried on in a set up to a certain point, and wonderfully loud signals will be the answer, but carry the regeneration or feedback just a little bit too far, and the advantage is lost, for then your receiver becomes a violent producer of oscillations, and you will wake the neighborhood by an overproduction of "birdies" which will cause people to swear and will not get you anything. The obvious thing to do in that case is to reduce your regeneration control to a finer point.

Another method of clearing up distorted signals can be had by the use of a small capacity condenser across the phone terminals. This will ofttimes clear up a signal when all else has failed, provided, of course, that the distortion does not have its origin in one of the other causes.

Teaching Radio in Sleep Proves Success

FURTHER reports from the Naval Air Station at Pensacola, Fla., on the success attained in teaching radio code to student aviators in their sleep shows progress in this novel and useful experiment. The experimental stage in the trials has been passed and the method has become standard as a means of saving students from failure.

When the test was started 12 students were unsatisfactory in their progress in radio code. After two nights, during which radio code was sent to the students in their sleep, only two of the students were unsatisfactory, and these two men left before the experiment was finished, professing disbelief in it.

The procedure has been to have the students sleep on the tables in the radio room where the code is taught in the regular school periods. Operators send messages at varying speeds all night.

The Supervisor of Radio for Atlanta, Ga.—Walter Van Nostrand, Jr.—will open his office in the Federal Building soon, it was announced at the Department of Commerce last week. Orders directing him to proceed from his old station at Norfolk have been issued, and he was expected to leave for Atlanta immediately.

* * *

Major Edw. H. Armstrong, to whom was granted Patent No. 1,113,149 for the regenerative circuit, one of the most valuable in the radio industry, had a tough time to get started. After he had made his invention he asked his father and his uncle for money to secure a patent and both refused. However, he had his drawings witnessed before a notary and thereby recorded his discovery. He filed an application for a patent on October 29, 1913, which was granted on October 6, 1914. In spite of numerous attacks the courts have sustained and protected Major Armstrong's patent in every instance. The invention was made while he was a student at Columbia University, New York City.

Los Angeles Mayor Awards Radio Medals

(C. Keystone View Co.)

The first radio operators to receive decorations for meritorious service in time of extreme peril were the three on the S. S. "City of Honolulu," which burned and sank in mid-Pacific. The Radio Corporation of America donated the medals which were presented to the operators by Mayor George C. Cryer, of Los Angeles, Cal. The picture shows the mayor at the extreme left congratulating them. Left to right they are Mayor Cryer, N. C. Kuller, third operator; Walter P. Bell, chief operator, and H. D. Hancock, second operator. The Mayor's secretary on the extreme right.

The "Wouff-Hongs" Will Be at the Chicago Convention

CHICAGO, ILL.—Initiation of candidates into the Royal Order of the "Wouff-Hong" will be one of the principal features on the last evening "night of mystery" at the Second National American Radio Relay League Convention which is to be held here September 12-15 under the auspices of the Chicago Radio Traffic Association. Convention headquarters will be the Edgewater Beach Hotel.

The order of the mysterious "Wouff-Hong" has become an institution in amateur radio and its membership is spreading rapidly over the entire country wherever there are radio men. The word is believed to have originated with the "Old Man," for years a contributor to the amateur magazine "QST," but whose real identity and general status in amateur radio has never been revealed.

One story has it that the "Wouff-Hong" is an instrument used to eliminate interference by annihilation of those who are over zealous in their use of the ether. What is reputed to be an exact replica of this "deadly" weapon, somewhat resembling in its construction an Indian tomahawk, actually exists.

As a secret order the "Wouff-Hong" had its beginning at an amateur convention in Flint, Michigan, at which time several hundred candidates were initiated. Interest developed to such an extent that another meeting was staged at an Ohio convention.

Through the traffic system of the American Radio Relay League the fame of the order has been spread far and wide, with the result that a constitution and ritual may be adopted formally in Chicago and the "Wouff-Hong" will hold henceforth a unique place in amateur radio affairs.

Latest developments in amateur and broadcast reception and transmission will be covered by speakers of national reputation, according to R. H. G. Mathews, central division manager of the league, and committeemen in charge of the convention program.

A "Neutro-Generative" Receiver

By C. White, Consulting Engineer

RADIO-FREQUENCY amplification and regenerative receivers have had one common fault—the tendency to oscillate. With the latter it has been possible to exert very good control over this tendency by the proper construction of the working parts and the correct amount of control. In fact, some regenerative receivers have such a fine degree of control that it is easily possible to tune in distant stations without allowing the tube to oscillate in order to get the carrier wave whistle by the zero beat note method. The very function of regeneration is holding the detector tube on the verge of oscillation, but not allowing it to "spill over." But radio-frequency amplification is amplifying the radio-frequency carrier wave before detection, and does not in any way depend upon holding the tube or tubes on the verge of oscillation as in the case of regeneration. Yet it is often true that

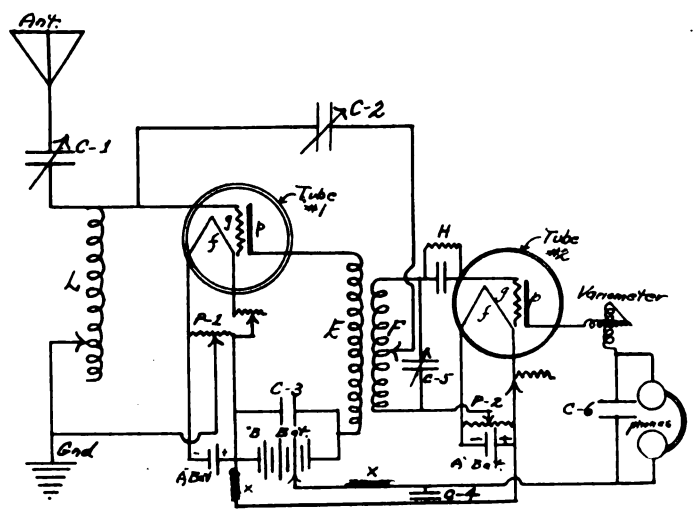

Diagram of a two-tube receiver that embodies several excellent features. It is a radio-frequency amplifier, which is regenerative, and at the same time will not oscillate violently beyond the "spill over" point due to the neutrodyne principle that is employed. It is simple to construct, requiring the construction and winding of but three coils, two of which are tapped. Audio-frequency amplification can be added, but, as shown in the diagram, separate batteries should be used for that purpose. Sufficiently loud signals will be possible with this receiver if headphones are wanted, and the clearness and quietness of operation will satisfy the most critical.

when a tube is on the best part of its radio-frequency amplifying characteristic it is very apt to "spill over" and spoil the amplification. To prevent this spilling over or oscillating various methods or dodges have been resorted to. One common method is the insertion of a resistance by means of a potentiometer in the filament-grid circuit of the amplifier tube which produces no serious harm when the tube is amplifying but introduces high losses if the tube tends to spill over or oscillate. It acts as a check on the tube action. But lately another method of prevention has been used, namely, the "neutrodyne" method, wherein the capacity of the tube element is balanced or neutralized by a condenser of very small capacity.

I shall not endeavor to go into the discussion of the merits of various methods, but only to say that the receiver here outlined combines in some respects the essential parts of each of the three systems. Of course, if it is desired to economize and cut down the number of controls the two potentiometers P-1 and P-2, in the diagram herewith, can be omitted and the grid returns of the tubes No. 1 and No. 2 can be connected to their respective negative sides of the "A" battery. Still, I think that the presence of these controls affords a control of volume as well as quality and are well worth their trouble and expense. The inductance coil L is wound on 4" tubing, having 60 turns in all of No. 22 S. C. C. magnet wire tapped at every tenth turn for a switch point. The coil F is constructed in the same identical manner, while the coil E is wound on 3½" tubing with 60 turns of No. 22 S. C. C. untapped. The coil E is placed inside of the coil F, and the overall length of the unit L and the unit E-F will not exceed 3½" apiece. The condensers are as follows: C-1 23 plates with vernier attachment; C-2, a very small two plate vernier condenser; C-3, a .5 mfd. condenser; C-4, the same as C-3; C-5, an 11 or 13 plate condenser with vernier attachment; and C-6, a .002 mfd. phone by-pass condenser. The manner in which these condensers are actually connected in the circuit will certainly make a lot of difference, so I advise a close following of these instructions. The condenser C-1 has the movable plates connected to the Ant., C-2 has the fixed plates connected to the grid of tube No. 1 and the movable to the switch-arm on coil F, while C-5 has the fixed plates nearest the grid of tube No. 2.

It is of the utmost importance to carefully shield this set with copper foil so as to prevent howling and annoying body capacity. The choke coils X have an inductance of .1 henry and are iron core chokes. This set is designed to operate with the new UV199, hence two separate "A" batteries are recommended. These batteries can be of the flashlight size since these tubes draw very little current, above .06 ampere. The grid leak H to be used with the UV199 or C299 should be variable from two to five megohms and a grid condenser of .00025 mfd. is advised. The filament rheostats should have a resistance of about 30 ohms apiece. The potentiometers P-1 and P-2 should have a resistance of 400 ohms apiece and be non-inductive. Any good variometer will do as a plate inductance on tube No. 2.

This receiver operates best with a very short aerial and is far more selective and clearer than when a long outdoor aerial is used. Tuning a station is in control of the inductance taps on L, the condenser C-1, and the condenser C-5. The variometer controls the volume to a certain extent. The taps on the coil F and the condenser C-2 should be adjusted so as to prevent oscillation at all wave length ranges of the receiver. If this is not possible with your particular receiver then the wave length bands will have to be grouped and a setting for each group will correspond to a definite calibration on C-2 and F. After C-2 and the taps of F have been ascertained there is no more guess work or further adjustment necessary. The set is very flexible and it will be soon discovered that several good adjustments can be made for each station, but there is always one that gives the best results. When properly built the receiver is very efficient, but care must be exercised to see that it is properly constructed. Grid leads must be kept as short as possible, and all wires should be well insulated with spaghetti. Audio-frequency amplification can be used with this receiver. It will be found advisable to use separate "A" and "B" batteries for the amplifier, however, in order to keep the outfit quiet working. Since UV199 tubes are used the extra expense is not very heavy and the results produced certainly warrant it.

Method of Sensitizing the Telegraphone

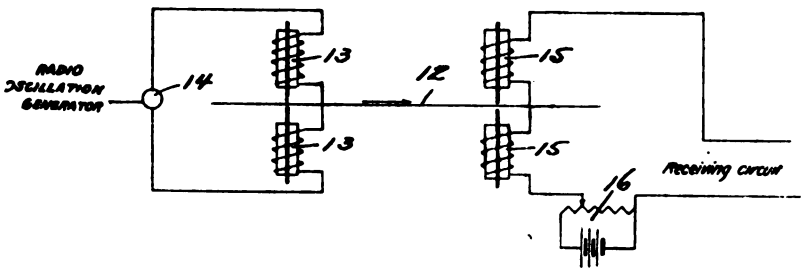
No. 1,450,282: Patented June 19, 1923. Patentee: L. F. Fuller, Palo Alto, Cal.

The telegraphone, as is well known, comprises an instrument in which a magnetizable wire or surface is locally magnetized in varying degrees at successive points along the wire or surface and at this spot magnetization persists, so that a record is produced on the wire or surface which may be subsequently reproduced. An object of this invention is to sensitize the telegraphone so that it will record magnetically on its wire very much weaker electrical impulses transmitted to its magnetizing coils than is at present possible.

The invention possesses other advantageous features, some of which with the foregoing, will be set forth at length in the following description, where I shall outline in full that form of the invention which I have selected for illustration in the drawings accompanying and forming part of the present specification. In said drawings I have shown two forms of apparatus for carrying out the method of my invention, but it is to be understood that I do not limit myself to such forms, since the method may be performed with other forms of apparatus.

An object of the invention is to sensitize the telegraphone so that it may be used for high speed radio signal recording, submarine cable signal recording, long distance telephone message recording and the recording of other weak electrical impulses.

Attempts have been made in the past to use the telegraphone for high speed receiving, but these attempts have been mostly unsuccessful, due to the insensitiveness of the telegraphone, which required abnormally strong signals to cause a record on the telegraphone wire.



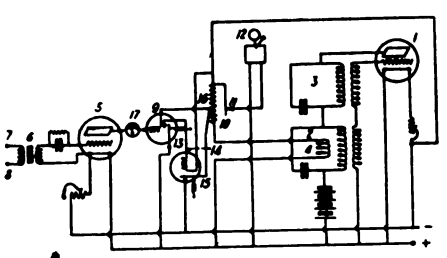
Method used to sensitize the movable recording wire of a telegraphone making it sensitive to much weaker impulses than is now possible. It is applicable to radio recording devices.

Receiving System

No. 1,462,882: Patented July 24, 1923. Patentee: Henri Chereix, Paris, France.

The present invention relates to improvements in relays of the kind described in my copending applications Serial Nos. 496,667 and 496,668, filed August 29, 1921, and more particularly to an improved adaptation of the said relay for automatic calling arrangements in wireless telegraphy or telephony.

Generally speaking, the improvement effected by the present invention consists in the following: a vibrator system and a thermostat associated therewith for actuating a call indicating apparatus such as a bell is carried back to the circuit of the element that controls the oscillating conditions (comprising a three electrode tube arranged as a detector in accordance with the previous applications). The vibrator system is preferably arranged in a special manner by the combination of the two electro-magnetic relays.



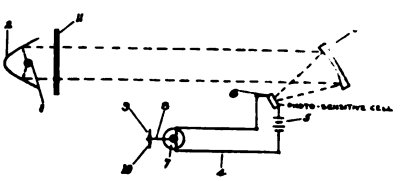
Means of providing an electrical call system that may be actuated by means of radio. Electronic relays are used in connection with tuned circuits specially designed to operate magnetic relays upon reception of certain waves.

* * *

System of Electrical Control

No. 1,458,165: Patented June 12, 1923. Patentee: W. W. Coblentz, Washington, D. C.

This invention has reference to improvements in a system of electrical control, having for its object to provide a novel apparatus and method of thermal radio dynamic control of mechanisms whereby to render possible the remote control of various mechanisms possible and practical through the use of light reactive material interposed in the control circuit and adapted, with the projection of certain colors of light rays from a point distant thereonto, to have its electrical conductivity either increased or decreased whereby to vary the passage of current through the circuit and to bring about the desired operation.



Improved method of controlling electrical circuits by means of beams of colored light projected to affect photo-sensitive cells, which in turn actuate sensitive magnetic relays.

Antenna Selector Switch

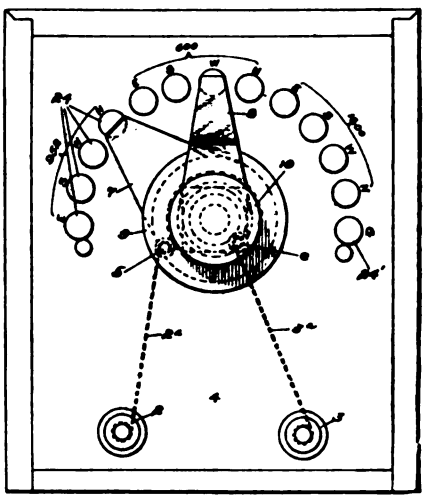
No. 1,456,466: Patented June 12, 1923. Patentee: Alfred Crossley, Washington, D. C.

My invention relates broadly to underground radio receiving systems and more particularly to a switching device for use as a selector to connect various combinations of antennae to the radio receiving apparatus for directive reception.

The object of my invention is to provide a practical selector switch capable of rapid manipulation to connect various combinations of underground, elevated or loop antennae to the receiving apparatus.

Another object of the invention is to provide in an antenna switch construction means for insuring perfect electrical contact of the switch elements.

My invention will be understood by reference to the accompanying drawings which form a part of this specification and in which like reference characters have been used to indicate like parts throughout the several views.



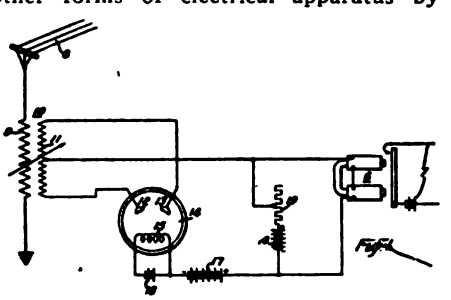
Apparatus and means for rapidly switching receiving apparatus from one antenna system to another. This method is especially applicable to underground antenna systems, which possess marked directional effects, thereby giving a great degree of selectivity.

* * *

Receiver for Wireless Impulses

No. 1,456,567: Patented May 29, 1923. Patentee: Frank Conrad, Pittsburgh, Pa.

This invention relates to apparatus for the receipt of wireless impulses and it has for its object to provide apparatus of the character designated that shall enable one to distantly control relays or other forms of electrical apparatus by means of wireless impulses and, at the same time, to substantially prevent the operation of such apparatus by other than the impulses intended therefor. The accompanying drawing is a diagrammatic view of a system embodying the invention, being shown for the wireless control of a distant relay.



Means of actuating a relay by other vibrations. The apparatus can be used to control machinery at a distance and to control any electrical circuit from the same point.

Answers to Readers of Radio World

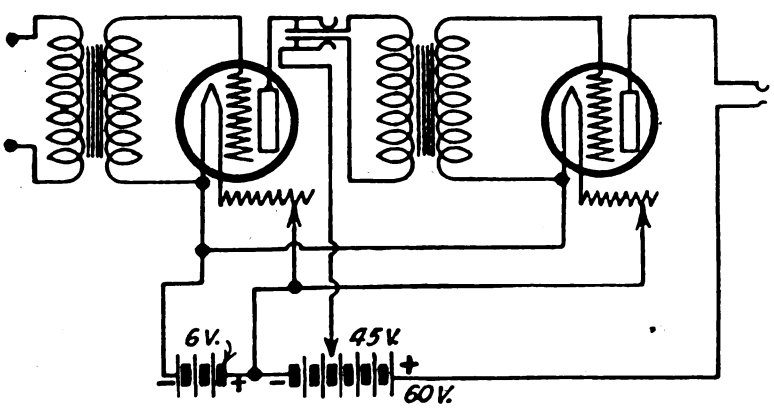
In RADIO WORLD, *July 7, you published a Lighthouse Receiver. What size wire is used on the coils, and what size are the former? Also what size variable condenser is used?—W. K. McClain, Lawrence, Kans.*

For the coils mentioned No. 26 SCC wire is sufficient. The former should be cut out of fibre or heavy cardboard, and should be four inches outside diameter with a core one inch across. The number of turns is shown in the diagram. A .0005 variable condenser is sufficient.

* * *

Enclosed find a circuit published in RADIO WORLD, *June 23, by A. D. Turnbull. Kindly give me a correct hook-up to use with it. Where should I tap the variometer? Which is the positive side of the B battery? Kindly give me a two-stage amplifying circuit for use with this circuit.—Y. T. Harvey, New York City.*

Your question is vague. The hook-up as you show it and as it is in the magazine are identical, and both are correct. If you mean a panel layout for such a set, we do not handle them, as we leave the design of the set up to the builder. The variometer is tapped at the connection of the stator and rotor, which is generally made by means of the shafting that runs through the rotor. The amplifying circuit you mention is printed herewith.



Schematic diagram of a suitable two-stage amplifier asked for by Y. T. Harvey, New York. The circuit is shown using separate A and B batteries from the detector circuit. This prevents any chance of feedback through the battery leads from the detector.

* * *

Is the Grimes inverse duplex circuit superior to the De Forest reflex as used in the D7 receiver? I intend using Acme A2 transformers, and Acme radio-frequency transformers. Which type do you recommend as being the best? Could I use an outside antenna and variocoupler as tuner instead of the loop as described?—Teddy Kuss, Pine City, Minn.

We cannot discuss the relative capabilities of the various circuits in comparison with manufactured apparatus. However, you will not make any mistake in constructing the circuit you mention if great care is taken. In reflex circuits the greatest care must be observed in wiring, as well as in the selection of the parts.

You can use the type of radio-frequency transformers you mention. The numbers they go by signify the wave length that they are supposed to tune to. Therefore determine beforehand just what wave length you wish to receive over and buy your transformers accordingly.

You can use a coupler and antenna and ground by simply connecting them across the terminals of the condenser that shunt the loop. Numerous articles have appeared in RADIO WORLD showing tuning units that can easily be constructed for this purpose.

* * *

I have built a two tube reflex, with crystal detector, according to diagram enclosed. My trouble lies in getting any distant stations, and also in keeping them after I once get them. They just seem to fade out, and I cannot get them any more. The entire set oscillates very easily; as a matter of fact, I cannot stop it from oscillating. My apparatus is all the best make and has worked in a one tube reflex successfully.—Wayne H. Merrick, Caldwell, Idaho.

Your diagram for a two tube reflex set is absolutely correct, and is the ordinary two tube reflex circuit using crystal detector. The fact that your set is oscillating is due to inter-coupling between the transformers. Separate them by a sufficient distance and if possible have their cores at right angles to one another. Shielding your panel carefully might help the fading of stations after you have them tuned in. Do not run your leads parallel to one another for too great a distance and use varnished cambric tubing to insulate them.

* * *

Do W. D. 12 tubes require a different hook-up than that used by the regular six volt tubes? I am using three of these tubes as radio-frequency amplifiers but cannot seem to get the third stage to work successfully.—John Gallub, Box 65, Chatham, N. Y.

These tubes do not require a special circuit. Examine the transformer of your third stage. Your trouble may lie in the fact that you have a defective transformer, which is the only thing that would cause your trouble if your set is correctly wired.

* * *

I have constructed the Cockaday circuit described by R. P. May in RADIO WORLD. *It works fine, but I am puzzled as to the need of the switch S in the drawing. I have left it at the place shown in the drawing but it does not seem to be necessary. When should I use it?—F. W. Kerchner, Glen Corbon, Ill.*

In the tuning in of distant stations it is sometimes necessary to use this switch. It has a neutralizing effect on the third tube and allows finer tuning by allowing a bias to be placed on the grid, or to allow a certain capacity feedback on the third tube, which will help in certain cases. You must experiment in each case and find out just which works best.

* * *

I am enclosing a circuit diagram using one stage of radio-frequency, detector and two stages of audio-frequency. Do you think that a transformer would work better than the tuned impedance coil that I am now using?—John Hauge, R. 1, Box 21, Ulen, Minn.

The circuit diagram you enclose has one error. The condenser and grid leak should be placed in the grid leak of the second tube instead of the first. As it is you are using it as a detector instead of an amplifier.

If you make this change the circuit should work satisfactorily. This type of radio-frequency is more efficient than transformer coupled, inasmuch as you can tune your R. F. tubes and get better tuning. By all means keep the present set, and just change the grid leak as directed.

* * *

In RADIO WORLD, *July 21, was described a midget set by Dick Roberts. Will you kindly furnish a diagram of the set as described? Will you kindly furnish all the constructional details, such as the winding of the coil and the apparatus and size of wire used in the set. What kind of a tube is used?—Newton Dringel, 14 Johnston St., Wilkinsburg, Pa. S. K. Fountain, Rocky Mt. N. C. Frank Kontout, P. O. Box 270. Oakville, Conn. L. J. Snyder, Pierson, Iowa. Harry J. Hubbard, 64 Katherine St. New Bedford, Mass. J. Schwartz, 3409 Benitan Ave., Detroit, Mich. G. H. Richardson, 310 Filmore Ave., Plainfield, N. J. Walter C. Sperber, 146 West 62nd St., New York City. Mathew Jordan, 33 Coenties Slip, New York City. Anthony Suir, Shoreham, N. Y. John A. Dengler, Jr., 218½ N. Minn St., New Ulm, Minn. Dr. Hugo S. Thomson, 535½ Main St., Springfield, Mass.*

The diagram as well as the constructional details of the circuit are published in this issue of RADIO WORLD. The address of Dick Roberts is Box 573, Miami, Oklahoma.

* * *

In the upper right hand corner of page 17 of RADIO WORLD, *July 14, you show a new loud speaker, which I have heard was invented in France and is said to be a wonder. Can you give me some information as to where it can be obtained?—Arthur Hammikson, Prince Bros. Service, Sayre, Okla.*

We do not see any mention of the new loud speaker. The picture in question shows a Marconi wagon being used to initiate the rural towns of England to radio. The speaker used looks to us like a regular loud speaker with a straight horn instead of a curved one.

* * *

I recently bought a W. D. 12 tube which was supposed to be new. After a week's use it ceased to light. Is there any way of determining whether it was a rebuilt tube that was sold to me for a new tube? Can I buy these tubes directly from the manufacturer? —Alf Hjembo, 11 Stephens Place, Port Richmond, N. Y.

There is no way in which you can determine whether a tube has been re-built if it is done cleverly. If the tube was sold in a sealed box, the manufacturer guarantees it, but not after use. You can buy these tubes from the manufacturer.

* * *

I have constructed the W. D. 11 circuit described by Ortherus Gordon in RADIO WORLD *for Jan. 20. Three people have looked over it and cannot get it to function. I cannot get a single sound out of it. Kindly tell me what is the trouble.—C. M. Adams, Alpine, Washington.*

Reverse your B battery leads so that the plus will go to the phones and plate and see if that does not help you out.

Digitized by Google

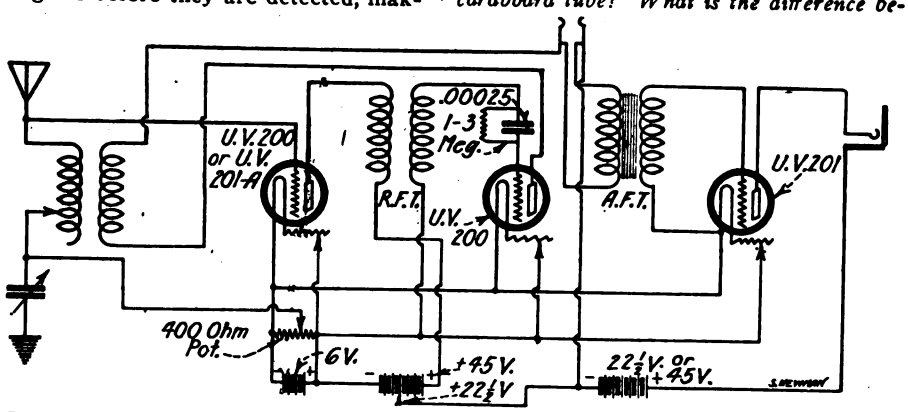
Will you kindly give me the following information: The constructional details of the "moving coil" element of the Magnavox. Also the details of the step down transformer that is used.—Harry A. Higginbotham, Orland, California.

As this is a patented device, the details must be secured from the manufacturer.

* * *

I have built the set described by Arthur S. Gordon in RADIO WORLD, *April* 14. *I now wish to add either one stage of radio-frequency amplification, or an additional stage of audio-frequency amplification, whichever you think will be best to increase my distance. What kind of tube should I use? What type of transformer? I am using a UV-200 for detector and a Cunningham for the audio-frequency amplification. What tube should I use for the circuit you mention? Will I need any additional batteries? Will the additional tube you mention enable me to operate a loud-speaker? — Charles G. Rose, P. O., Lorain, Ohio.*

The circuit you desire is published herewith with the addition of one stage of radio-frequency amplification, which is the best method of increasing the distance of a receiver. Audio-frequency will not increase distance, as it will only amplify signals that are audible with the detector itself, whereas radio-frequency amplifies the signals before they are detected, making possible signals that would not be audible without it. A hard amplifying tube such as the UV 201 or 201A is best for this purpose in the six-volt tubes. The transformer is optional—buy the best you can, as we do not recommend any types of competitive apparatus. An additional 22½ or 45 volt B battery in the plate circuit of the third tube will be necessary, as shown. It is questionable if a single step of radio added to the set you mention will increase your volume enough to enable you to operate a loud speaker. Radio-frequency does not increase volume so much as distance, and you will notice only a slight increase. With a set such as this, however, you should be able to get fair results on local stations with one stage of audio.



Circuit diagram asked for by Charles G. Rose. It is the Sorenson circuit with an additional stage of radio-frequency for distant reception. Extreme care should be taken in the rewiring of the circuit if good results are to be expected. Do not run wires parallel and watch your battery leads.

* * *

In RADIO WORLD, *June* 23, *you published a diagram of the D7 De Forest reflex circuit. Will this circuit produce as loud signals as a regenerative receiver using a detector and two steps of amplification? What capacity is the condenser between the secondaries of the third radio-frequency transformer and the crystal detector? Where can I purchase the .0015 condensers, as well as others of high values? Would separate rheostats for each tube rather than single control be of any advantage?—C. H. Barnett, Box 384, Hagerman, New Mexico.*

This circuit properly constructed and operated will produce louder signals and get further distance than the circuit you mention. When you are using a circuit of this type you are getting the practical use of six tubes, compared with the three that you would get through the circuit you mention. The capacity of the condenser should be either .002 or .0015. The condensers can be purchased from dealers handling the Dubilier or Freshman apparatus. There would be no advantage in using separate rheostats and the controls would be complicated by their use. Stick to the original diagrams and plans in all circuits of this type if you expect to succeed. Half the failures are due to some bright idea that the builder gets when constructing the set.

* * *

What is the best type of coil to use in the "pup" circuit? How many turns should be used, and what is the position of the tap? Is it better to wind your own coils? If so, will you give me the details for doing same? —C. J. Neymaber, 735 Main Street, San Angelo, Tex.

A duo-lateral or honeycomb coil is preferable for use with this circuit. Use either a 50 or 75. The coil should be tapped at the designated turn from the inside. No advantage will be gained by the winding of your own coils unless you have all the means for doing it correctly.

* * *

Will it be of advantage to use a bakelite tube in the set described by R. B. Wilbur in RADIO WORLD *for July* 28 *instead of a cardboard tube? What is the difference between a 23-plate .0001 and a 23-plate .005 condenser?—August Grubel, 331 East 38th Street, New York City.*

It is of decided advantage to use bakelite in place of cardboard wherever it is possible in the construction of coils. We do not know that anybody is making condensers of the .0001 capacity with 23 plates, but answering your question regarding the difference between them it is that the capacity of the .005 is fifty times as great as the smaller. We are not aware that these condensers are sold on the open market in that value of capacity. The general run of 23 plate condensers is .0005 mfd, and that of the 43 plate .001. Short waves are generally considered as anything below 600 and long waves anything above that. Due to recent allocations, however, the waves around 200 meters may be considered as short waves, and those from 600 up as the long waves, while those in between would be classed as intermediate waves.

* * *

Which of the two circuits, the Grimes inverse duplex or the improved Grimes duplex, is the best circuit for distance reception?—J. G. Jones, 3409 Beniteau Avenue, Detroit, Mich.

The Grimes inverse duplex is popular in two forms, the three tube and the four tube. You do not state which you mean. The improved Grimes as shown in RADIO WORLD is identical with the three tube set, the only difference being that Mr. Thompson has designed it to incorporate a stage of pure radio-frequency amplification ahead of the reflex tubes. Both are good sets.

Radio Products

R3 Magnavox Radio The Reproducer Supreme

Make Your Receiving Set Complete

The efficiency of the Magnavox Reproducer is due to its principle of construction.

Only the Magnavox (electro-dynamic) reproducer can re-create broadcasted programs according to their original *pitch, quality* and *volume.*

Without Magnavox equipment, no Radio receiving set is complete.

Magnavox R3 Reproducer and 2 stage Power Amplifier . . . **$90.00**

R2 Magnavox Reproducer with 18-inch curvex horn: the utmost in amplifying power; requires only .6 of an ampere for the field **$60.00**

R3 Magnavox Reproducer with 14-inch curvex horn: ideal for homes, offices, etc. . . . **$35.00**

Model C Magnavox Power Amplifier insures getting the largest possible power input for your Magnavox Reproducer.

AC-2-C, 2-stage, $55.00
AC-3-C, 3-stage, $75.00

Magnavox Radio products can be had of good dealers everywhere. Write for copy of our new booklet.

Mayor Curley, of Boston, Makes Broadcasting Suggestions

EDITOR, RADIO WORLD: I beg to acknowledge receipt of your letter of recent date and replying thereto beg to state that, realizing the complications which have arisen on account of the increasing popularity of radio broadcasting and the evident necessity for some form of regulation or control, I am led to believe that eventually a municipally controlled broadcasting station in various cities of the country may be the means of meeting present conditions as well as provide for the future development of radio service.

Boston is fortunate in having at least two first class radio stations whose broadcasting is known throughout the country, besides the Government station controlled by the Navy. So long as these stations serve the requirements and continue to be as willing as they have been heretofore to co-operate with any municipal requirement I hesitate to suggest that the City of Boston establish its own station at this time.

I believe that the real solution of the radio broadcasting situation is to have the proper national government agency plan for the proper supervision and regulation of this service as it already does in some matters and should with regard to a great many more matters in which the service and welfare of the people are concerned.

Very truly yours,
JAMES C. CURLEY,
Boston, Mass. Mayor.

A Loud Speaker Tip

MANY times when a loud speaker is used with two steps of audio-frequency amplification, the diaphragm of the loud speaking phone has a tendency to rattle. If the loud speaking phone is of the type that resembles a regulation telephone and the diaphragm can be removed, cut a small washer of thin cardboard just the size of the phone and about the thickness of the rim of the phone, and place it under the diaphragm. This will lift the diaphragm above the pole pieces of the magnets a slight bit and stop the rattle, which is caused by it hitting the pole pieces.

Do not use thick cardboard, or the distance will be too great and the sound will be impaired. The cardboard used by the laundries to keep shirt bosoms straight will be about right. Also be sure to keep the cap screwed on tightly or else the rattle will be worse than before.

Another Appeal to Our Readers

EDITOR, RADIO WORLD:

I am a cripple and have not walked, except on crutches, since I was nine years old. I am now 37. I have always been self-supporting since I was 15 until the last year. I am not able to get about very well. I have necrosis or tuberculosis of the bone.

I am very much interested in radio. I was thinking of making a crystal set, but since the discontinuance of KFAT at Eugene, Ore. (20 miles from here), I will have to have at least a single tube set, if I am to enjoy radio.

If any of the readers of RADIO WORLD who have some spare parts they no longer need will kindly send them to me, I am able to build a set myself. I sure will appreciate them. Respectfully yours,

C. R. COCHRAN.
Box 434, Cottage Grove, Ore.

(RADIO WORLD has investigated Mr. Cochran's statements and finds them correct. His case seems to be deserving. Readers who care to accede to his request are advised to correspond directly with Mr. Cochran.—Editor.)

Radio Literature Wanted

Manufacturers of and dealers in radio apparatus and accessories are notified that literature and catalogues describing their products have been requested, through the Service Editor of RADIO WORLD, by the following:

George Usher, Box 63, Miami, Fla.
J. J. Borris, 508 North Fifth St., Harrison, N. J.
Franklin Washburn, 1240 Allston St., Houston, Texas.
W. T. Praster, 46 North Main St., Pleasantville, N. J. (Retailer.)
Dr. O. E. Johnson, Rock Rapids, Iowa.
S. C. Quinn, Northern Pacific Ticket Office, Bismarck, North Dakota.
Robert A. Sage, 223 North Fourth Ave., Washington, Iowa.
V. M. Smith, 309 West Latham Ave., Hemet, California.
Martin N. Jefferson, 2920 East 97th St., South Chicago, Ill. (Will soon open large radio service station. In market for radio goods of all kinds.)
George M. Butler, 5 Ashland Terrace, New Bedford, Mass. (Wants low cost crystal set for mail order trade.)
Fred Cochrane, Jr., A. I. R. E., 137 East 122nd St., New York, N. Y.
James Boa Company, Ltd., 10 St. Sophie Lane, Montreal, P. Q., Canada. (Will do a strictly wholesale radio business. Want lowest jobbing prices from manufacturers.)
George T. Zaffer, Winston Electric Co., 75 Union St., Flushing, N. Y. (Distributor and retailer.)
The H. Wellman Electric & Mfg. Co., Ashland, Ky. (Has organized a radio department and will soon stock up for early fall trade.)
Ivan H. White, 315 Joseph St., Charleston, W. Va.
H. H. Rockenbach, Fairbury, Ill.
J. A. Hawthorne, 3049 Ocean Ave., Brooklyn, N. Y. (Distributor.)
Joseph Powers, 51 Gardner St., Allston, Mass.
C. E. Whalen, North Amherst, Mass.
Jos. A. Cross, 428 East Lane Ave., Columbus, Ohio.

Coming Events

AMERICAN RADIO EXPOSITION, Grand Central Palace, New York City, October 6 to 13, 1923. J. C. Johnson, general manager.

ANNUAL HOME AND CITY BEAUTIFUL EXPOSITION, featuring radio exhibits, Atlantic City, N. J., June 16 to September 8, 1923.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS, Pacific Coast convention, Del Monte, Cal., Oct. 2-5. F. L. Hutchinson, 33 West 39th St., New York.

The Indorarial

THE C. B. Cooper Company, 154 Nassau street, New York City, are sole selling agents for the "Indorarial," which resembles a piece of wall paper with a metal strip at each end. It can be rolled up and carried, making a good aerial for a portable set. Placed in a closet or under a rug, it makes an efficient indoor aerial which is out of sight. Interesting results are obtained by various combinations of one or more Indorarials.

Radio World's Remarkable Subscription Achievement

ONE of the most difficult things in the publishing business is the building up of a subscription list. A year ago subscriptions came tumbling into the office of RADIO WORLD. That was all very well, but we wondered at the time if it was simply evidence of the fact that everybody was radio crazy. Would RADIO WORLD stand the gaff when it came to renewals?

RADIO WORLD is standing it, and amazing those who have had years of experience in the publishing business. The large percentage of renewals received on expired subscriptions is extraordinary. An army of people not only subscribed for RADIO WORLD last year, but are renewing their subscriptions this year—even in the summer time—in a manner seldom known in publishing experience.

In other words, RADIO WORLD has qualified. It has achieved that enviable position where it can say of its subscribers and newsstand purchasers with almost literal truth, "Once a reader, always a reader."

Ask the average publisher what he thinks of the statement that any publication can, besides daily adding new subscribers in large numbers to its list, induce almost 90% of its old subscribers to renew. Most publishers would say it is impossible. RADIO WORLD is doing it right now, and has the renewal orders to prove it.

THE BUSINESS MANAGER.

Newark, N. J., Making 3500 "Bootleg" Vacuum Tubes a Day

By William McNeary

Radio Editor, Newark Sunday Call

THE bootlegging of vacuum tubes used in radio receiving sets has grown to be one of the most widely practiced and highly profitable by-products of prohibition. Its importance is second only to the business of rum-smuggling itself. With a potential market of nearly a million dollars worth of tubes per month, the radio bootlegger is playing a big game. His net profit is generally as large, if not larger, than that of the whiskey runner and his danger of apprehension and punishment seems much less.

Beginning about a year ago on a small scale with the manufacture of various crude types of tubes which were easily spotted, the radio bootlegger has developed his business to the point of so skilfully and accurately counterfeiting the products of several prominent manufacturers that only an expert is able to detect the difference. In the course of examining the receiving sets of about forty amateurs a day for the past year and a half, the Newark Sunday *Call* has been afforded an unusual opportunity of examining a large variety of vacuum tubes, and whereas it was formerly a very simple matter to detect a bootleg product because of its faulty construction, the job has now become one requiring the closest examination.

The manufacture of the so-called "standard" vacuum tubes is in the hands of a closely knit group comprising the General Electric Company and the Westinghouse Electric & Manufacturing Company, from whose factories come the UV200, UV201, UV201-A, UV199, WD11, WD12 and, in addition, a series of tubes used largely in transmitting circuits. These tubes are sold through the Radio Corporation of America to the jobbers and dealers of the country. From the General Electric factories also come a series of tubes identically the same as listed above, but bearing the trade designation C300, C301, C301-A, C299, C11 and C12 and the signature of E. T. Cunningham. These tubes are widely used on the Pacific Coast and have recently been introduced into New Jersey.

Another important manufacturer of standard tubes is the Western Electric Company, makers of the VT1 and VT2, used extensively by the Signal Corps of the United States Army, the 216-A used as a power amplifier and the "N" (peanut) tube employed as a detector, as well as a radio and audio amplifier. The latter tube, although not sold for amateur and experimental use in this country has attracted considerable attention here. The interest thus aroused has been capitalized by the bootleggers, who have placed copies of this tube on the market.

The development of "standard" vacuum tubes to their present high point of efficiency has been achieved only after the expenditure of hundreds of thousands of dollars by the companies mentioned above. The patents resulting from this costly experimentation represent a form of protection for the manufacturer against the pirates of industry who seek to profit by the fruits of another's labor and brains.

Patents mean nothing to the radio bootlegger, however. Not only does he steal the fundamental principle which has taken a legitimate firm years to develop, but he completes the job to the last detail by counterfeiting the tube in size, shape and even in the design of the trademark.

Newark is reported to be the biggest source of bootleg vacuum tubes in the country, but, strangely enough, fewer bootleg tubes are sold in this city than in any radio center of its size and importance in the United States. The local public is afforded a large measure of protection through the integrity of the dealers and through the medium of the personal service feature of the Sunday *Call's* Radio Department, which is available for testing tubes and apparatus every day except Monday from 2 to 5 P. M. A constant watch over the radio market is maintained by the *Call's* staff for the protection and information of its readers. Because of this fact radio bootleggers find it more profitable to seek other dumping grounds for their products.

From a source believed to be very reliable the Sunday *Call* learns that there are approximately seven "factories" engaged in the manufacture of bootleg tubes in this city. The combined capacity of these plants is figured at 3,500 tubes a day. There are five additional factories in New York and Brooklyn, this latter group being capable of producing about 2,000 tubes a day.

The reason Newark is such a big manufacturing center for bootleg tubes is because this city and vicinity affords the greatest market for skilled labor and materials, vital necessities to the bootlegger. In Harrison, just across the Passaic River from Newark, is the General Electric plant, employing thousands of workers, mostly girls, on the various processes of vacuum tube construction. In Bloomfield, another suburban town, is the Westinghouse Lamp Works, also employing thousands of trained workers on radio tubes. In these factories inexperienced labor is taken and thoroughly trained in the delicate work of tube making. Once thoroughly trained and experienced, this labor is recruited by agents of the bootlegger who are known to have approached workers leaving the factories. Higher wages is the usual bait, but bonuses are offered to the girls skilled in the more delicate branches of the work.

With this labor at his command the bootlegger is better able to carry out the details of counterfeiting standard tubes. There have come to the attention of the Sunday *Call* some excellent copies of the UV199. It is difficult to tell the copy from the original. Its weakness is in its extremely short filament life, the average bootleg lasting only a few hours as against 1,000 hours, the normal service of a standard tube. The bootleg 199's examined have a higher rate of current consumption than the genuine and a low percentage of electron emission, which means poorer service. This is largely because the bootlegger is unable to obtain the proper filament material and is obliged to substitute a flattened platinum wire, which, incidentally, is also obtainable locally.

The counterfeit UV199 is distinguished by the fact that the R. C. A., G. E. and W. trademarks impressed in white on the glass may be erased by rubbing a moistened finger over them. On the genuine these trademarks are etched on the glass and cannot be removed. The printing on the base of the tube is frequently badly smudged on the bootleg, whereas on the genuine it is quite clear and readable.

In addition to counterfeit UV199, the Sunday *Call* has discovered fake Western Electric "N" tubes, UV200 and UV201, DeForest DV6, WD12 and UV201-A.

Radio Trade Notes

Frank La Valle, 2529 Cambrilling Ave., New York City, informs RADIO WORLD that he would like to go into the radio retail business and wants to hear from manufacturers of parts.

* * *

C. B. Gowan and R. L. Lockett, 515 Galveston Ave., Fort Worth, Texas, are in the market for radio supplies, especially parts.

* * *

The L. C. Warner Co. has removed to large quarters at 305 Occidental Ave., Seattle, Wash.

A. W. Stitt & Co., 127 York St., Sydney, Australia, want to import all kinds of radio apparatus.

* * *

Sterling Miles Radio Co., 288 Judson St., Pontiac, Mich., is in the market for parts, radio books and mailing lists.

* * *

Geo. W. Reeffin, 41 Fifth Ave., Brooklyn, N. Y., wants electrical measuring instruments, coils and other parts.

* * *

Shippard Radio Co., 315 East State St., Jacksonville, Ill., wants prices on an extensive list of parts.

The Condenser Sensation of Modern Radio

Through the accuracy and dependability of Freshman Condensers, hook-ups and circuits have been perfected which have completely revolutionized the art of Radio Reception.

These little Storers of energy and rectifiers of Radio Current are the very heart of a well-built radio set.

The proper fixed condenser will make all the difference in the world in the reception, clarity and selectivity your set affords.

Capacity	Each	Capacity	Each
.0001	$ .35	.002	$ .40
.00015	.35	.0025	.50
.00025	.35	.003	.60
.0002	.35	.004	.75
.0003	.35	.005	.75
.00035	.39	.006	.75
.0005	.35	.008	1.00
.0006	.40	.01	1.00
.0008	.40	.015	1.50
.001	.40	.02	2.00
.0015	.40	.025	2.50

The FRESHMAN is so designed that constant equal pressure is exerted on the condenser plates over the entire area. They are the only condensers that do this and therefore the only condensers that avoid noises, which are due to variable pressure on the plates.

At your dealers, otherwise send purchase price and you will be supplied postpaid.

Public Health Service Warns Against Poison Ivy and Poison Oak

VACATIONISTS who carried their radio receiving sets with them on their jaunts this summer are not suffering from the want of advice on health. Thirty broadcasting stations in addition to NAA, Naval Radio Station, Arlington, Va., have been releasing health hints for vacationists furnished by the Bureau of the United States Public Health Service at Washington. The most recent of these broadcasts on the subject of poison ivy is especially timely, since every summer brings its toll of suffering from this cause.

The poison ivy is perhaps the plant most frequently encountered by the unsuspecting city visitor to the country, says the Public Health Service. Yet it may be easily distinguished from other creepers by its three divided leaves. The harmless creepers have five leaves. This one distinguishing mark if borne in mind will protect the vacationist from poison ivy. Poison oak is a shrub or small tree with broad leaves very much resembling the leaves of the oak tree.

The part of these plants to be feared is the resinous sap. When a plant is injured this sticky sap exudes. It comes in contact with the skin and sets up an irritation which is distinguished by its acute character. This irritation frequently begins between the fingers.

The symptoms of ivy poisoning are comparatively easy to recognize. A more or less mild attack may be ushered in by a burning or itching of the skin. Within twenty-four hours after the skin is exposed to the poison of the plant, a red rash appears. This is followed by more or less swelling and itching; then small blisters filled with serum make their appearance. The parts of the body affected may swell to enormous proportions.

At one time it was believed that many persons who had suffered from attacks of ivy poisoning would experience a recurrence of the attack if they passed through a wood or came into proximity with the plant even though the ivy itself was not touched. It now appears certain, however, that contact is necessary in order to produce ivy poisoning.

Ivy poisoning, says the Public Health Service, may sometimes be averted even after these plants have been handled provided the parts exposed are washed thoroughly with soap, water and alcohol. This washing must, however, be thorough, otherwise it will only tend to spread the irritating poison.

The treatment of ivy poisoning is simple and easily administered. One of the best treatments is bathing with salt water. Sea water is best if it is available. Another good application consists of one teaspoonful of boric acid in a quart of hot water. The affected parts should be bathed with warm water every day or every two days and carefully dried without rubbing. Bathing should be followed by another application of boric acid. The attack may subside in from four to six days. The best advice to vacationists is, study the poison oak, the poison ivy and the poison sumac so you may distingush these plants from their neighbors. Once you are able to recognize them you can scrupulously avoid them. Avoid the creeper with the three divided leaves. Avoid the small shrub with the broad leaves like the oak. Give the sumac that grows in swampy places a wide berth. Persons who have suffered from plant poison do not soon forget the experience .

A $300 Prize Contest for Radio Music

DO we have our jazz regularly with our bedtime story or not? That is the question that now confronts hundreds of thousands of families who have invested in radio receiving sets as they sit back awaiting the result of the broadcaster-music trust controversy.

It started with the sort of half scared claim of the publishers and authors of popular music several months ago, that the use of their compositions for radio broadcasting purposes was detrimental to its sale and, incidentally, disastrous to the profit sides of their ledgers.

The broadcasters, rendering a free service to the public, contended that the broadcasting of these compositions could have but one effect upon them—an increase in their popularity with an according increase in their sale. And so the matter stood for several months.

The claim of the publishers has ceased to be a whimper. It has now developed into a demand, a bold demand for royalties that, if necessary, will be backed to the limit by legal action.

With locked horns the opposing factions are now marking time and in the meantime the great fraternity of radio fans sits back and awaits judgment on what, to them, is an important question.

Radio News, a publication devoted to the interests of radio, has stepped in, not to referee the bout, but to attempt to solve what is a problem of concern to hundreds of thousands of families that have made room, at more or less expense, for this new means of emanating canned music. A decision negative to the interests of this great fraternity will undoubtedly bring about even a greater wail than that of the dreaded static or ether hog.

The solvent, that purposed to unlock the horns and bring the controversants to a state of amiability and more congenial relationship will be the publication, by *Radio News*, of two musical compositions, one a march and the other a "jazz" piece, which will be chosen in open competition, and promoted entirely by radio.

The popularity of these songs, the success of their sale, will be traceable directly to their use as radio broadcasting selections as they will not be promoted through any other medium. This success, which seems to be measured by the number of office boys who whistle it, will be the proof of the contention that radio broadcasting helps to "make" a song.

In the September issue of *Radio News*, Mr. H. Gernsback, editor of that publication, states, editorially, that radio has made many a bad show good and has had the same effect upon music, that is, radio has not changed the quality of either but it has done much to increase attendance and sale of good shows with poor attendances and good music with poor sales records.

Those who will judge the contest will be Hugo Reisenfeld, conductor of the orchestras of the Rialto, Rivoli and Criterion theaters of New York; Ted Lewis, of the well known Ted Lewis band and Ted Lewis Frolics; Vincent Lopez, director of the Hotel Pennsylvania orchestra, New York; Milton J. Cross, announcer of radio broadcasting station, AJN, New York, member of the Institute of Musical Arts and of Paulist Choristers; Leo B. Riggs, musical director of the Hotel Astor Bands, and H. Gernsback, editor of *Radio News*.

Three hundred dollars in prizes will be awarded in the contest, one-half for the best composition in march time and a like amount for the best composition in "jazz" time. The winning contestants will also be paid a generous royalty upon the sale of their compositions so that two new popular song writers will also be "made" by radio

The conditions of the competition, as mentioned in the September issue of *Radio News*, follows:

1. Each composition to be not longer than the usual four pages.
2. Contestants may send in more than one composition. There is no restriction as to number.
3. All compositions to be executed in the usual manner, using the usual musical symbols.
4. Compositions to be entitled "Radio March" or "Radio Jazz," as the case may be.
5. Authors unable to write down music themselves, may have a musician do this for them.
6. All manuscripts to be submitted flat, not rolled.
7. All manuscripts not accepted will be promptly returned to the owners at the conclusion of the contest, provided sufficient postage is enclosed with the manuscripts.
8. All prizes will be paid upon publication.
9. This contest closes in New York on October 1, 1923.
10. Address all contributions to Editor, Radio Music Contest, *Radio News*, New York.

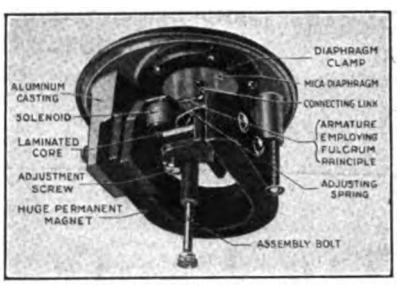
THE TRINITY LOUD SPEAKER

TYPE "A1"
21" FIBER
HORN
$25.00

TYPE "B"
(For Phonographs)
$12.50



INTERIOR CONSTRUCTION

An ear phone is an ear phone no matter how fancy the horn that covers it may be, and, due to the delicate construction of an ear phone it is utterly incapable of giving true tone reproduction, especially, when relatively large currents are passed thru its coils, such as the output of a two-stage or power amplifier.

The Trinity Loud Speaker element embodies the well-proven and tested principles of the phonograph reproducer with the soundest principles of electromagnetic design best adapted for loud speaker operation. It is not an ear phone when placed on a head band and a loud speaker when covered with a horn. It is a sturdy loud-speaking element ALWAYS.

Send for Literature.

Real Value of Radio to the Blind and Deaf

IN lieu of the inspiration which the artist derives from the up-turned expectant faces of her audience, the singer at the radio broadcasting station, if she has imagination, can picture hundreds of homes where sit invalids, blind men and women and even many deaf people, thrilled at her every note.

Letters which come to the radio broadcasting station emphasize the enjoyment which the "stay-at-homes" get from broadcast music. To many of them "air" entertainment is the only pleasure that breaks the monotony of passing time. To many radio brings for a time at least forgetfulness of suffering. One such letter is that received recently by the General Electric Company station WGY at Schenectady, N. Y., from a young blind woman who lives in Seneca Falls, N. Y. She was graduated from college after working her way through aided by the limited means of her parents. While taking a year's work in normal school to fit herself for teaching a serious illness brought on blindness. She had to provide a living for herself, her aged father and mother and she became a masseuse. Writing to WGY, she says:

"If you could know how much we enjoy the voice of the Schenectady station, you would be glad that God gave you such a gift. My father, who is very hard of hearing can hear you distinctly and knows your voice already although we are only two weeks old in the radio world. Father could get nearly all the service and sang the hymns with the choir.

"The work of massage is so very exhausting that even when there is an invitation to get some recreation, physical weariness makes it impossible to enjoy anything. The constant association with sick people, the worry of expense and the strain of trying to do things without sight, the care of a father who has been feeble a long time, and the anxiety of a mother 74 years old who has had to work so hard to serve a deaf husband and a blind daughter, all these things brought me to a dreadful state of mind, distrusting everybody and sorry for myself. No honors conferred on a celebrity could have given greater pleasure than the church service gave two people, one deaf and the other blind and hungry for something good and helpful. The talk which I heard about Christ and Christianity was a greater banquet than any that was ever spread before the greatest man.

"I do wish that some philanthropist who would like to do something for the blind would furnish radio sets to those who are less fortunate than I."

Subscribe for RADIO WORLD, $6.00 a year, $3.00 six months, $1.50 three months.

Price, $5.00. The Columbia Print, 1493 Broadway, New York City.

ELEMENTS OF RADIO TELEPHONY

By WILLIAM C. BALLARD, JR.

Assistant Professor of Electrical Engineering, Cornell University

This is a standard book on radio telephony, the work of a recognized authority.

It is accurate, simple, clear, reliable and strictly up to date.

The man with a technical background who wants to post himself on radio will find this exactly the book for his purpose.

The radio enthusiast will find in it an excellent presentation of fundamental principles and their application.

SENT POSTPAID ON RECEIPT OF PRICE, $1.50, BY

THE COLUMBIA PRINT, 1493 B'way, New York City

DID YOU GET THE VACATION NUMBER OF RADIO WORLD

It had page after page of interesting and practical ideas and hook-ups for people who are going camping, canoeing, yachting, or just vacationing up in the mountains. You really can't afford to be without it, if you intend leaving the city behind this summer and want to take your radio with you. Dated June 2. Mailed for 15c.

Radio World, 1493 Broadway, New York City

RADIO FANS

Do you want to sell your old set?
Do you want to exchange anything for something?
Do you want to buy something?

If so, why don't you use the Classified Department of Radio World? You can get fine results for five cents a word, minimum ten words. Your message will reach thousands including other fans, dealers, etc., etc.

Try Radio World's Classified Department for your personal radio and other needs.

RADIO WORLD, 1493 Broadway, New York City

HOOK-UP AND CIRCUIT HOUNDS

Did you miss it? Do you want it? If you do you can get it by writing in to Radio World for any one of these back numbers, as per dates:

IMPORTANT NOTICE

While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

Business *Is* Good!

UNDER the title "A Calm Review of a Calm Man," Samuel G. Blythe writes a most absorbing article in *The Saturday Evening Post* about President Harding, in the course of which he says:

"This country, under Harding, has come to be the only legitimately prosperous country in the world. It doesn't take much of a memory to go back to 1921, nor much of a business training to realize that business was bad in this country at that time. Nor does it take much experience of economics or commerce, general trade, manufacturing or labor conditions to make it plain that this country, at this time, is really, legitimately, solidly and nationally prosperous. This prosperity is not sectional. It is not geographical. It extends from coast to coast, from the Canadian border to Mexico. Labor is universally employed at high wages. Money is plentiful. All lines of business are flourishing. And there is no other country in the world of which this can be said.

"That is the fact. Any banker will tell you so. Any business man will tell you so, any man of large affairs. Any workingman will tell you he has steady work at high wages. Times are good. Trade in every line is good. The country is on the big up-swing.

"This isn't a past condition, nor a future condition. It is a present condition."

What Is a "Radario"? Here's the Answer

T. C. O'DONNELL has written several plays and stories for children and spoken to a world-wide audience from Station WLW, Crosley Manufacturing Company, Cincinnati, "the station with a soul." His plays appear every month in *Child Life* magazine. He has made a study of the radarios written and produced at WLW, and has written the first original radario for children. This is called "The Magic Journey" and will be given in September from the broadcasting station.

There may be some new radio set owners who do not know that radario plays were originated by Fred Smith, director of the WLW studio, but most of the radio audience during the past year know about this and their enthusiastic letters have encouraged the production of these plays on even a larger scale than heretofore. Mr. O'Donnell, who is also editor of *Writer's Digest*, which is conducting a $100 prize contest for the three best radarios submitted, has this to say about them:

"The word radario can best be defined by giving a brief history of the broadcasting of one-act plays, as written for and produced upon the stage. In this, station WLW was the pioneer. It was found that with the aid of occasional interpolations by the studio director, describing the entrance and exit of characters, and with each part given by a reader with a distinctive voice, it was possible to render the play so clearly that the listener could readily follow the play.

"But—directions by the studio director did interrupt the dialogue and the action of the play, and to that degree the play failed to be perfectly adapted to radio broadcasting. Mr. Fred Smith, studio director at WLW, hit upon a means of obviating this difficulty. His idea was so to construct the play that the dialogue would convey to the listener the entire action.

"For example, in a scene with two young women conversing about the young man whom they are expecting, upon his appearance the studio director in the regular play would have said: 'At this point Reginald Fairfield enters and greets the young women.' The radioized version would be something in this manner:

"'PHYLLIS: Oh, here comes Reggie now! . . . . . Hello, Reggie!'

"'REGINALD: Why, here you are! Hello, Phyllis! Hello, Dorothy!' and the dialogue would go on smoothly and the entire action be as clear to the listener as though the studio director, or 'descriptionist,' as he is now called, had described the action.

"To this new form Mr. Smith gave the name 'radario,' a word which has quickly become fixed in the language, so that the publishers of the Standard Dictionary have announced that the next edition of this work would contain the word and its definition.

"Mr. Smith also wrote the first radario, 'When Love Wakens,' the title initials being the letters which denote the station WLW. This was broadcast early in the year and was followed by other radarios, one of these being a clever radioization, if we may use the term, of Moliere's 'Trader Turned Gentleman.'

"An essential of the radario is that it tell a complete story; in other words, that it have a plot. Also it must be brief, not occupying more than twenty minutes on the program. And if variety is introduced in the form of a song by one of the performers, or a bit of orchestra music, or a novelty like a whistling solo, so much

Genuine

What IS Genuine Orange Pekoe?

IT has nothing to do with oranges. "Orange Pekoe" is simply an oriental term to denote one of the different gradings of tea. And here is the point you should keep in mind when you buy Orange Pekoe Tea—There are three distinct gradings:

Flowery Orange Pekoe (tea of very finest quality)
Broken Orange Pekoe (tea of very choice quality)
Orange Pekoe (tea of average quality)

The first two grades are very much superior to ordinary Orange Pekoe. Ridgways *Genuine* Orange Pekoe is the finest tea procurable, because it is composed *only of the Flowery and Broken Orange Pekoes.*

Some teas marked "Orange Pekoe" have a very small proportion of Orange Pekoe. Right there is the value in getting *Genuine* Orange Pekoe.

The way to make sure of Genuine Orange Pekoe, without any doubt about it, is to insist firmly upon Ridgways *Genuine* Orange Pekoe. Then you are certain to enjoy the superb flavor, the exquisite bouquet you should rightfully expect in this superior tea. Order definitely by name and insist upon getting it. Ridgways GOLD LABEL *Genuine* Orange Pekoe.

The Sleeper Monotrol

The First of a Series of Three Articles Describing the Construction of the Latest Type of Grimes Inverse Reflex Receiver

By DAVID GRIMES

WHEN a new radio circuit, however wonderful in its essentials, is put to the acid test of commercial use, then every little detail must be explored, and every difficulty located and solved in order to produce an instrument that Mr. Average man or woman can operate with full success and pleasure. Ever since first announ-

small loops for reception, which were mounted in the aeroplanes directly behind the operator's seat, so that they could be rotated by him in the direction of maximum or minimum intensity. The set was placed beside the operator and the batteries at his feet.

The proble- -educing weight in -e bombing

This basic idea was not new, as it dated back to 1913 and 1914, with credit due to two Germans. These men had even taken out foreign patents, the United States patent having been granted to them in 1914. Most of the widely advertised one tube reflexes recently on the -ar- direct uses of the German

T- -sic idea showed

THIS was the first of three important articles describing the famous Grimes Inverse Duplex Circuit—latest and greatest of all 3-tube circuits as incorporated exclusively in the **SLEEPER MONOTROL**—"the most perfect radio set in America."

Both the set and articles describing it have caused a stir in the leading radio publications throughout the country. We will be glad to send you our booklet describing its extraordinary features.

Dealers

—will be particularly interested. They are looking for radio developments which have come to stay and the series of articles in "The Radio Sun-Globe" will convince the most skeptical that not only is the **SLEEPER MONOTROL** a distinct advance over previous sets, but a **permanent** advance—a fundamental principle. We will be glad to send complimentary reprints of these articles to all dealers who write for details of our special trade proposition.

ILLUSTRATED EVERY WEEK

YOU'RE NEVER ALONE IN THE WOODS—IF YOU HAVE RADIO

(C. Kadel and Herbert)

Gets sorta lonesome these days for the girls up in the mountains, when nearly all the boys have gone back to work. But these lucky misses, Peggy Stohl, Betty Nevins and Muriel Harrison, do not seem to mind simply because they had the forethought to take their radio set along with them up to their woodland home in the Adirondacks. The photographer wanted to know why they didn't dress and dance like regular wood nymphs, but they said the music for such things couldn't be had by means of a jazz band and that is all that was on at the time, so he had to be content with a tango fox trot.

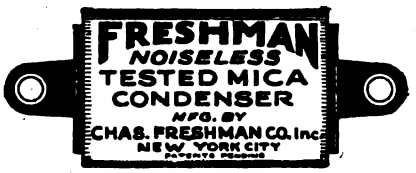
The Condenser Sensation of Modern Radio



Through the accuracy and dependability of Freshman Condensers, hook-ups and circuits have been perfected which have completely revolutionized the art of Radio Reception.

These little Stores of energy and rectifiers of Radio Current are the very heart of a well-built radio set.

The proper fixed condenser will make all the difference in the world in the reception, clarity and selectivity your set affords.

Capacity	Each	Capacity	Each
.0001	$ .35	.002	$ .40
.00015	.35	.0025	.50
.00025	.35	.003	.60
.0002	.35	.004	.75
.0003	.35	.005	.75
.00035	.35	.006	.75
.0005	.35	.008	1.00
.0006	.40	.01	1.00
.0008	.40	.015	1.50
.001	.40	.02	2.00
.0015	.40	.025	2.50

The FRESHMAN is so designed that constant equal pressure is exerted on the condenser plates over the entire area. They are the only condensers that do this and therefore the only condensers that avoid noises, which are due to variable pressure on the plates.

At your dealers, otherwise send purchase price and you will be supplied postpaid.

WGY Offers $500 Prize for Radio Drama

WGY, the radio broadcasting station of the General Electric Company at Schenectady, N. Y., offers a prize of $500 for the best radio drama submitted in competition during the three months' period beginning September 1.

The prize-winning play will be presented by the WGY Players during the winter months when transmission conditions are at their best.

The screen has evolved a distinct type of drama, which depends solely on the eye for its appreciation; tomorrow the radio drama will be so written that the listening ear and imagination unaided by the eye will be satisfied. It is for the purpose of stimulating and encouraging the development of the radio drama that the General Electric Company inaugurates this prize competition.

The author of the radio drama must place himself in the position of writing for a blind man. The lines of the characters must convey a picture of the scene in which the action takes place. This apparent limitation or handicap becomes an aid to action, however, as the writer need not restrict his play to three, four or five scenes. For example, he can depict an automobile race and carry his audience through its exciting phases by means of the lines. He may take his listener from room to room or floor to floor in a dwelling, if farce or melodrama call for such action. The chase, long a popular feature in the early motion pictures, may be brought into the radio play by means of speech. The radio drama requires no scenery. No careful search need be made for locations. The spoken words build the scenery.

Dramatic situations may be built up by the speaking voice and through the medium of sound-making devices. The writer is encouraged to make use of sound devices and the engineer will provide a means of producing through the air a counterpart of the prescribed sound. Rain, thunder, surf, the roar of a moving train, a pistol shot, an airplane, telegraph key or automobile motor may all be reproduced in sound to impart atmosphere and realism.

Those who have written short stories, books of fiction, scenarios or plays, successfully or unsuccessfully, may have the germ of a prize-winning radio drama. If you are interested address Prize Competition, WGY Broadcasting Studio, General Electric Company, Schenectady, N. Y., for a folder which sets forth the rules of the competition with an outline of the special requirements of the radio play.

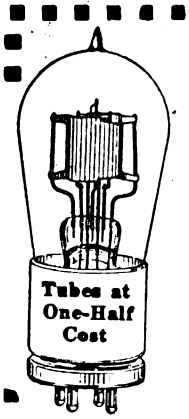
Station WEAF Sends Out Questionnaire

W. E. HARKNESS, manager of broadcasting for the American Telephone & Telegraph Company, New York, has sent to thousands of radio listeners in an elaborate questionnaire to which replies are requested without signatures. In an accompanying letter Mr. Harkness says:

"You want to have us provide you with the best possible programs. We want to do just this. You will realize that it is a difficult matter to cater to the tastes of an audience so large as that which we reach. In order that we may know more accurately of whom our audience is composed and what their desires are, we are sending the enclosed questionnaire to all our listeners who have been so kind and courteous as to write or telephone of their interest in Station WEAF.

"You will notice that the questionnaire is entirely impersonal and that you are not even asked to sign your name. All we want is to be able to compile statistics that will help us to conduct the station as efficiently as possible and to send on the air what will please our audience. A number of the questions may seem irrelevant, but we assure you that the information will help give us a real picture of our audience and their interests."



IT HAS HAPPENED TO ALL OF YOU IN A FRACTION OF A SECOND!

WHEN the filament burns out, at least $5.00 goes with it to put the set in operation again.

WHY not save nearly one-half the cost of a new tube by sending us your burned out or broken tube to be repaired?

WE REPAIR EVERY TYPE OF tungsten wire filament receiving tube. All our tubes are TESTED and GUARANTEED to function as well as when new.

All tubes returned P. P., C. O. D.

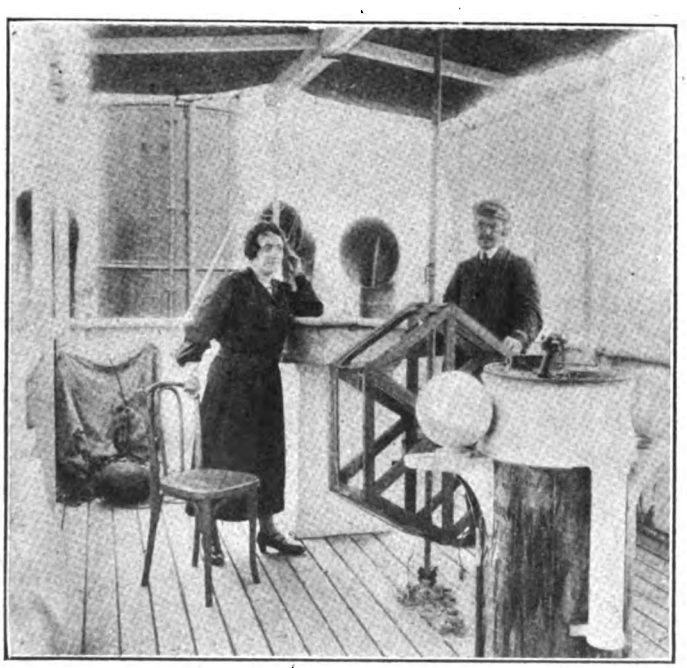
Details of a Ship's Radio Compass

By Captain L. Mauriet, S. S. "Syria"

IN RADIO WORLD, February 24, 1923, I described a receiver constructed by myself and used aboard my ship that was suitable for a compass receiver for ship bearings and fog signals, and also for the reception of broadcast programs from distant stations.

Since that time I have put in two more stages of both radio-frequency and audio-frequency which has added considerably to the range of my receiver. The same circuit was used for both the radio and audio-frequency as before so I do not think it necessary to furnish additional diagrams, as anybody can add the necessary apparatus by simply following out the original plans.

I use two stages of transformer coupled radio-frequency and the original one stage of resistance coupled radio-frequency because of the fact that I find that a stage of resistance coupled radio-frequency after two stages of transformer coupled radio-frequency has

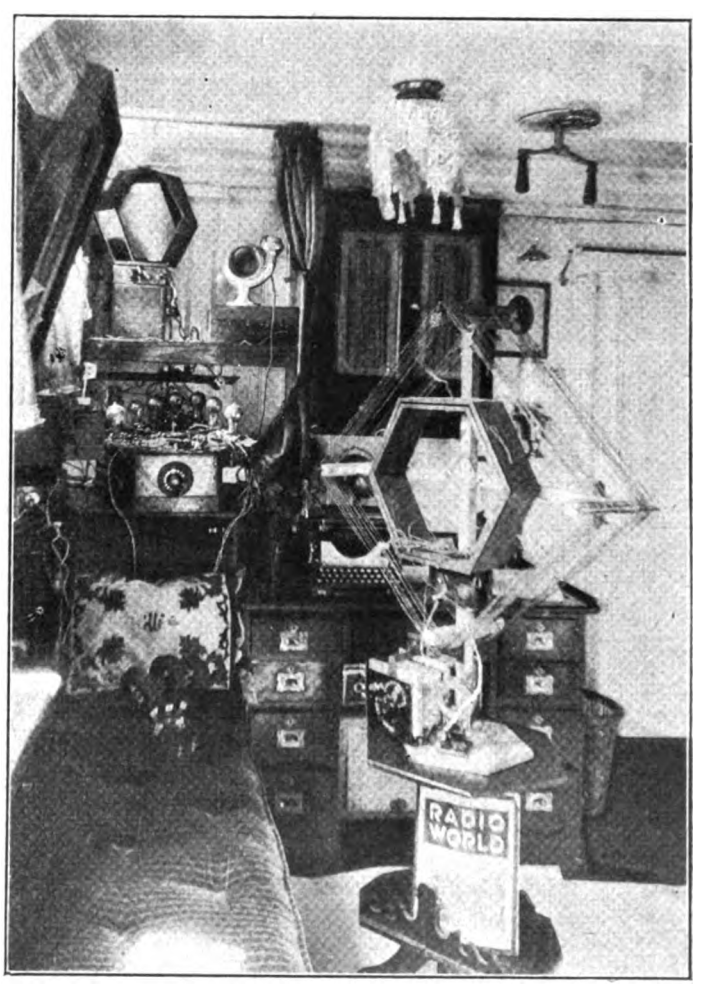


Navigating bridge of the S. S. "Syria" with radio compass. The loop antenna can be operated from the room below. Mrs. Mauriet and Captain Mauriet listening in to a program.

a stabilizing effect, making the set easier to handle. As to the audio-frequency, transformers are used throughout.

The set involves identically the same principle as the first, being constructed in four cabinets so shaped that they form a hexagon, as shown in the drawing. Connections are made by means of binding posts on the sides, with battery connections under the cabinet. This allows you to make a neat table of the entire set by setting it on a pedestal.

Of greater interest to ship builders and owners will be the construction of the practical loop, which is located on the top of the upper bridge, with the con-



In the captain's room on the S. S. "Syria." Seven-tube receiver at left and two forms of tuned loops. Handle to operate loop shown coming through from deck above.

trols passing through the deck to the cabin below, where the receiver is located.

The principal dimensions of the loop proper are: Vertical diameter, 3′ 3″; breadth, 10″; sides of hexagon, 1′ 6″; turns of wire, 20; total length of wire used, 180′. The loop standards are made of sound

Daylight Radio Test by Amateurs

HARTFORD, CONN.—On the morning of Sunday, September 23, radio amateurs of either coast will attempt to beat Old Sol across the continent in spectacular daylight tests. Their transmitters will be pitted against sunlight in their efforts to relay messages across the country between sunrise and sunset, according to an announcement made here by F. H. Schnell, traffic manager of the American Radio Relay League.

At least ten picked amateurs on both the Pacific and Atlantic Coasts will start messages as the sun comes over the horizon and they will be relayed by intervening stations. By evening it is expected that most of the messages will have reached their destination and, for the brass-pounders, the contest with Father Time will end in a radio victory.

These tests have a real scientific value since they will demonstrate to what extent the sun affects transmission. Everyone familiar with radio knows that reception over long distances is more difficult during the daytime than in darkness, this being caused, it is believed, by the ionization of the earth's atmosphere by the sun's rays.

The disastrous effect of sunlight upon radio has been noticed by broadcast listeners, as well as amateurs, and it is confidently expected by league officers that definite comparisons may be drawn which will prove helpful in an investigation of this subject.

In this connection some interesting information may be gathered from the experience of Donald H. Mix, league radio operator with the MacMillan exploration party bound for the Arctic, since he must transmit messages and news reports through both daylight and darkness from the Arctic seas to amateurs at home.

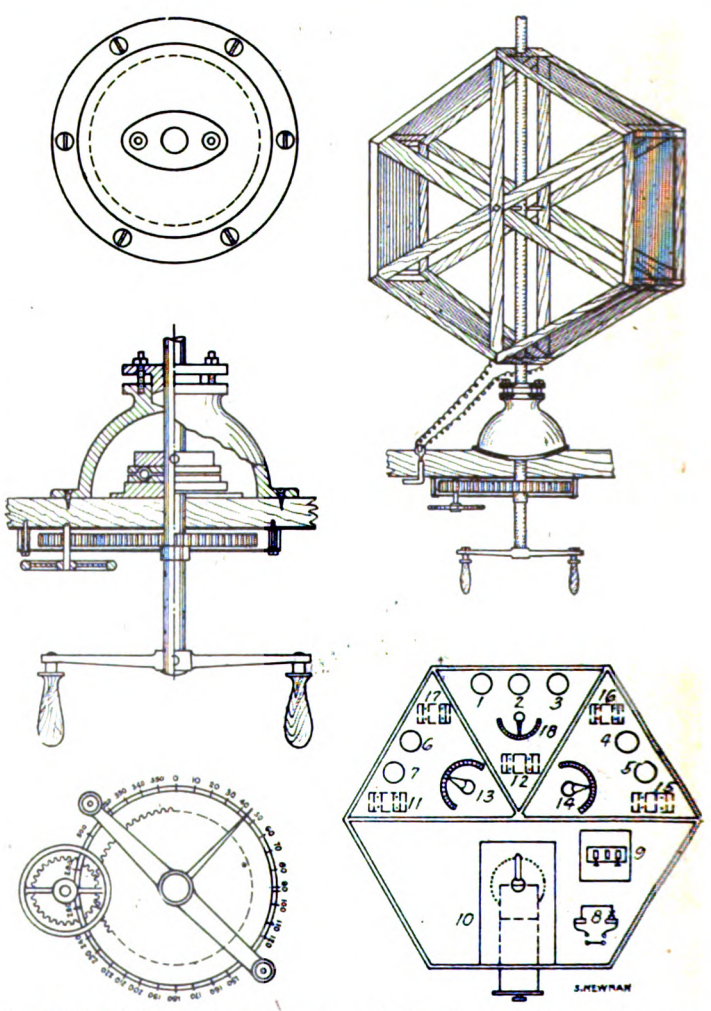
"No one will know from what stations the messages will start," says Mr. Schnell referring to the daylight tests. "Everybody will have the same chance of picking up a message and relaying it along the line." He advises all amateurs to keep a record of everything they hear and whether they use standard or daylight time. These records should be sent to A. R. R. L. headquarters at Hartford, Conn., by October first.

(*Concluded from preceding page*)

hardwood, such as oak or ash, which has been well kiln dried. The stock for the construction can be 1"x½" for all practical purposes, but for outdoor use I prefer to make it even heavier, using 1" square. Do not use iron nails or screws, or paint the standards as the metallic base of marine paint will form a conductor for the minute currents. Copper screws or nails should be used and countersunk, the top of the hole filled with putty and then the entire frame varnished with a good grade of marine varnish which is left to dry thoroughly before the wire is wound on.

The construction details of the stuffing box and bearings is clear from the drawings. They were constructed from odd material found laying around the engine room and consist of such odd parts as a Ford bearing and a discarded differential case (upper part, and two gear wheels). The handles are discarded control handles. Care should be taken if the installation is to be made on the deck that everything is carefully packed with oakum and oiled waste to prevent water from gaining entrance during a storm. The leads for the loop are brought down through a metallic bushing insulated with porcelain, and which has a heavy brass and porcelain collar to prevent leakage of water or radio energy. Such entrance insulators can easily be obtained from radio supply shops, as they are commonly used aboard ship to bring in the antenna.

By means of a chart located on the ceiling of the cabin and graduated into points of the compass bearings can be taken without having to take cross bearings, provided the course of the vessel is known, and the position of the transmitter on the map is known. The set will be accurate to a great degree, due to the construction of the loop and also to the sharpness of tuning obtained by use of the radio-frequency. If captains of ships realized the absolute comfort of knowing their bearings by radio, such as can be obtained by the use of the receiver described, every ship would have a loop receiver of some sort. During a fog when astronomical observations cannot be obtained for hours and sometimes days at a time, it is a great aid to the practiced navigator to be able to absolutely check his course in a few minutes and with as great accuracy as though observations were taken with the compass and sextant.



Constructional details of the loop for a ship's radio compass as well as the controls and packing box. Seven-tube receiver is shown in lower right hand corner. The references are as follows: 1—High frequency tube (radio-frequency); 2—Detector tube; 3—audio-frequency tube; 4-5—two stages of audio-frequency; 6-7—two stages of radio-frequency; 8—crystal detector; 9—honeycomb coils; 10—loose coupler; 11—radio-frequency transformer; 12—audio-frequency transformer; 13—condenser, 23 plates; 14—condenser, 43 plates; 15—audio-frequency transformer; 16—audio-frequency transformer; 17—radio-frequency transformer; 18—rheostat for detector tube. The set is made in four cabinets as shown—three triangular, containing the tubes, transformers and controls, and one large one containing the loose coupler, honeycomb coils and crystal detector.

How to Improve Your R. C. Set

By R. L. Dougherty

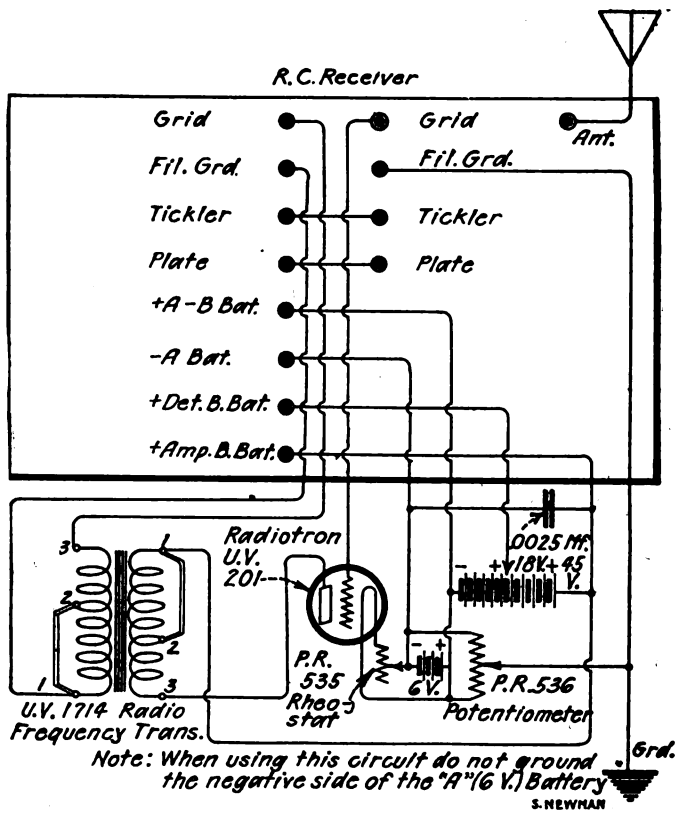
MANY purchasers of the now famous RC sets, or the RA-DA combination receiver and amplifier units are well satisfied with the work performed by these receivers. However, it is only natural that they should inquire whether there is any method of improving the distance of these receivers, and also several other details.

Strange as it may seem it is extremely simple to add a stage of radio-frequency to these sets, *without disturbing a single connection on the inside of the apparatus.* Fig. 1 illustrates the method evolved by the engineers of the Radio Corporation of America for adding a single stage of radio-frequency amplification to their RC receiver. As the RC and the RA-DA combination are identical in every detail excepting that the RC is in a single cabinet and the RA-DA is in two only one diagram is required. With the RA-DA sets, the two units are in separate cabinets and the unit for the radio-frequency can be made and fitted between the two. If this is neatly done, and the general style of the manufactured cabinets followed out, the appearance will in no wise detract from the purchased receiver.

Referring to Fig. 1 it will be noted that the same A and B batteries are used for the radio-frequency and the detector and two stage, which simplifies matters considerably, and while a UV201 tube is recommended, with a six volt battery, the set will function if WD12 tubes are used throughout, with 1½ volt dry cells.

Note the fact that a potentiometer is used across the A battery of the first tube. This is necessary to the correct operation of the circuit and should not be omitted. It is not advisable to add more than a single stage of radio-frequency as it has been discovered that

(*Concluded on next page*)



Showing how a stage of radio-frequency can be added to an RC or RA-DA combination without disturbing a single connection inside the set. All connections are made outside by means of flexible wire, or the unit can be made in a separate cabinet and wired as shown. Circuit diagrams supplied by Radio Corporation of America. (Fig. 1).

Diagram showing how it is possible to place a "C" battery in the DA unit of the RC set by the addition of two wires and the severing of the wire that taps on the rheostat of the audio-frequency filament control. The addition of this simple battery will make absolutely distortionless amplification on two steps possible. Carefully insulate and solder all leads, and trace connection before inserting tubes and turning on current. (Fig. 2).

Digitized by Google

(*Concluded from preceding page*)

the controls become so complicated that tuning with any degree of accuracy is almost impossible. For that reason only one stage is shown. Furthermore, as regeneration is used in combination with radio-frequency the set is perfectly capable of bringing in sufficiently distant stations to satisfy any except the fan who insists on hearing Los Angeles in New York.

Another handy hint that is sponsored by the Radio Corporation of America's engineers is the addition of a C battery in the grid circuit of the two stage amplifiers. It has been found that when working on two steps, or even one step, that there was some distortion due, of course, to a positive charge on the grid of the amplifier tube. In order to remove this, and give absolutely clear amplification free from distortion, a C battery was found absolutely necessary.

Any one can, with the help of a soldering iron, a little patience and a great deal of care in tracing the wires correctly add a C battery to this receiver in an hour's time. The battery may consist of a single dry cell battery such as used in the flat type flashlights, connected as shown in Fig. 2, and will last quite a long time, of course, depending upon the use that the amplifier is put to.

The use of the C battery will also conserve the A battery as it will not be necessary to burn the amplifiers up as high as before it was added. The diagram shows how by the addition of two wires, and the removal of one, the change can be accomplished.

Be sure that you have your connections right, however, before actually putting the set to use, as a wrong or crossed connection would cause trouble, and probably result in the blowing of two tubes should you have the set connected wrong.

With the addition of these two ideas it is possible to make your RC receiver a real long distance receiver capable of bringing in distant stations on your loud talker, with the minimum amount of labor and absolutely distortionless signals. As a further note it will be found that the radio-frequency signals will be clearest with a minimum amount of tickler in the circuit, but that, of course, will depend upon the operation of the set itself, and no fixed point can be recommended, but mention is made of it so that it can be used to advantage by any one who constructs the additional part and installs the necessary C battery.

Users of this type of receiver have doubtless noted the fact that when the tickler is turned down, it takes more current in the filament circuit to make the tube oscillate. If during the operation of the set, the tickler is turned down two or three taps, unless it is a local station, the signals will fade out. Now if the tickler inductance is turned down to the point at where the signals are just barely audible, and adjustment is made with the vernier until the signals are heard at their clearest and best, and the filament of the detector tube is turned up just slightly, it will be found that the signals are much louder and clearer than if they had been haphazardly tuned in.

Lighthouse Service Designs a Portable Receiving Set

By S. R. Winters

NOVICES and amateurs in the wireless game who may experience difficulty in hoisting antenna wires to tall trees, should profit from the experience of A. W. Tupper, assistant engineer of the Lighthouse Service, United States' Department of Commerce. At his residence in Washington, D. C., he selected an oak tree of big dimensions for supporting the antenna wires. The first limb on this tree was about thirty feet from the ground, a condition which made it well-nigh impossible to climb the tree.

Evidently recalling his boyhood days when a bow was employed in shooting an arrow to dizzy heights, he considered its use for sending the antenna wire over the 90-foot tree. Consequently, one end of an arrow was loaded with lead and then tied to a string and shot over the oak tree. His first attempts were unsuccessful, but after repeated trials he succeeded. The completed antenna was 100 feet long, 30 feet high at the lower end and 70 feet at the upper end.

This particular antenna serves the experimental purpose of the use of a model radio-telephone receiving set designed by the Lighthouse Service for the keepers of lighthouses along our 44,000 miles of coast line. A radio club has been formed in Washington, about 50 of its 60 members being keepers of lighthouses. As an outgrowth of this, the Washington office of the Lighthouse Service has prepared blueprints of a portable wireless receiving set.

This compact radio-telephone receiving outfit, which is equally as adaptable to the home as to the lighthouse, weighs only a little more than twelve pounds, including the cabinet, instruments, and batteries. Only one WD-11 vacuum tube is used. A dry-cell battery of 1½ volts lights the filament, and the plate circuit derives its electric energy from a 22-volt dry cell battery. Storage batteries are, therefore, dispensed with. The electric current consumed by this single vacuum tube in detecting and amplifying the wireless signals is almost negligible, the glow of the bulb being barely discernible.

Directions for building receiver as published by the Lighthouse Service using two spiderweb variometers, prescribe that the following apparatus as necessary:

1 WD-11 or other 1½ volt tube; 1 tube receptacle to fit tube; 1 pair of headphones; 1 22½ volt B battery; 1 dry cell; 1 23 or 43 plate variable condenser with vernier; 1 phone condenser, .0025 mfd.; 1 grid condenser, .0005 mfd.; 1 grid leak; 1 piece of fiber or hard bristol board about 1/32" thick and 8" square; ¼ pound No. 26 gauge enameled magnet wire; 1 rheostat for filament; 1 piece ¼" diameter dowel stock 5" long, 1 piece ½" diameter dowel stock 8¼" long; 7 feet tinned copper bus bar wire or heavy bell wire; 1 piece of tinfoil large enough to cover panel for shielding; 4 binding posts; 4 machine screws, No. 6, ½" long, with nuts; 1 piece brass 1/16" thick, ⅝" wide and 6" long for making end supports for coil shafts; 2 knobs and dials; 3 dozen copper wire terminals; 1 piece of bakelite, hard rubber, or perfectly dry, close grained wood for panel, size ¼"x13"x10¾".

The entire construction of this set is quite simple. The only difficulty likely to be experienced is in making proper connections with the spider-web coils. If the diagram is carefully followed, however, no serious

Digitized by Google

trouble will be found. One important point must be borne in mind. Each pair of coils must be assembled so that when the coils are together and viewed from one side the wire in each will be turning in the same direction. It is well to mark each coil with an arrow near the center of both sides, indicating the direction in which the wire is turning in passing from the center of the coil to the outside or end. Then when you assemble the coils, arrange them so that the arrow on each pair of coils is pointing in the same direction. If this is not done, it will be rather hard to determine the direction once they are on the set. Leave a connection wire about eight inches long at the beginning and end of each coil.

The shafts which hold the movable coils are made of a wood dowel. These shafts pass through the front

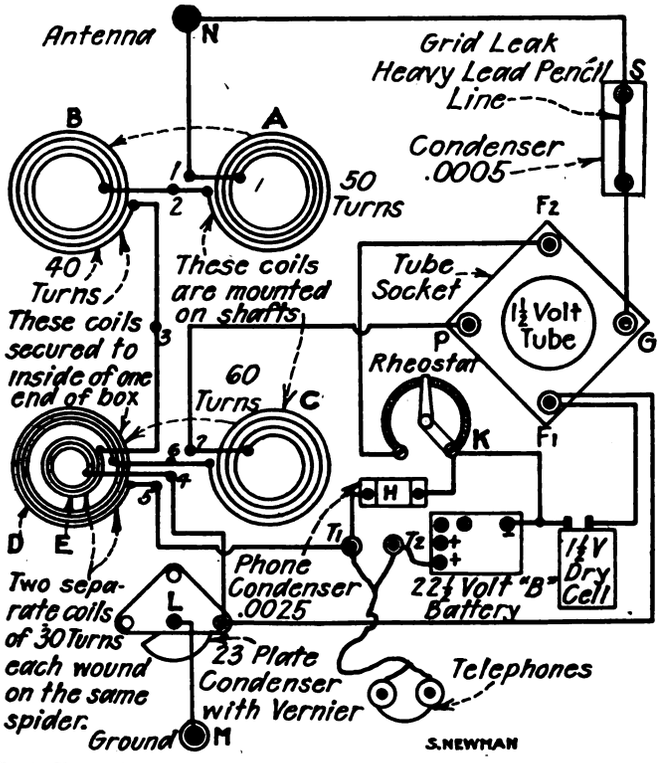

Fig. 1. Circuit diagram of lighthouse receiver using two spiderweb variometers. The figures 1 to 7 correspond with the numerals on the connection block shown in Fig. 2. Be sure to connect the rotary plates of the condenser L to the ground wire, to prevent capacity effect and howls.

panel and should be fitted with knobs on the front to permit manipulation of the coils. The rear end of the shaft should be sharpened to a cone-shaped point which will fit into a hole drilled in the spring brass elbow as shown in the drawing. This hole should be small enough to prevent the entire dowel passing through—⅛" is sufficient. The elbow should press with enough tension against the dowel to prevent the coils turning when in a horizontal position. The dowel is prevented from being pushed out of the front of the panel by either a screw collar, which can be made from a discarded spool, which holds it against the panel, or a pin passed through the dowel at the proper place.

The formers for the spider-web coils are cut from heavy cardboard. They are 4" outside diameter, the center being 1¼" diameter. Each has nine slots, giving an uneven number so that no two adjacent wires will cross on the same side of a given sector. After the wire is wound the entire coil should be given a coat of collodion, coil cement or thin white shellac, which is allowed to dry thoroughly. This is to prevent the wires working loose and to keep moisture out of the board. Four formers will be needed for the set, wound as directed on the diagram.

The cabinet for containing this compact radio-receiving set was built by the engineering construction division of the Lighthouse Service. It is made of common pine timber and is stained with a color resembling mahogany. The cabinet is covered with two coats of shellac. The panel board is made of seasoned oak, but rubber or bakelite may be used, being about 3/16" thick. The panel is first drilled and two coats of shellac applied if a wood panel is used. One coat of the latter is given to the holes in the panel, this application aiding in the prevention of moisture penetrating the wood. The back of the panel is covered with a sheet of tinfoil and the latter is grounded. The tinfoil was secured to the panel while the shellac was in a moist or soft condition. At points where the wireless instruments are attached to the panel the tinfoil is cut away as a means of avoiding electrical connections with the panel.

Since this portable radio-telephone receiving equipment is homemade, the cost of all the necessary parts will not exceed $20. The simplicity of adjustment and operation of this portable set are factors which recommend its widespread adoption in lighthouses and in rural communities where people may have only a limited knowledge of electricity. Six of these model

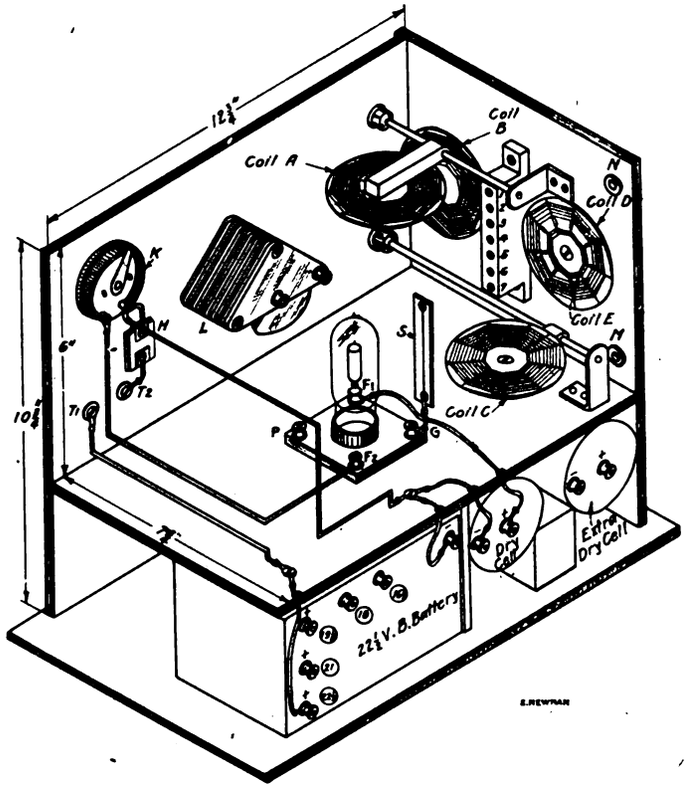

Fig. 2. Interior view of the completed lighthouse receiver with the filament circuit and B battery circuit wired to show the style to be followed. All other connections are made according to wiring diagram and brought to the connection block located between two stationary coils on inner right hand side. Numbers and letters in Fig. 1 correspond with lettering on the block to simplify connecting.

outfits have already been built by the Washington office of the Lighthouse Service, and their efficiency in the reception of radio communications has been sufficiently demonstrated. If atmospheric conditions are favorable, music and speech may be heard in Washington when emanating from Boston, Chicago, Detroit, Kansas City, Atlanta, Davenport, and occasionally Havana, Cuba. For instance, signals have been received in Washington from Buffalo with the rheostat placed at the extreme point of resistance.

The Lighthouse Service has written and published five pages of text outlining the details of this set.

Navy the First Broadcaster

By Col. Theodore Roosevelt

Acting Secretary of the Navy

THE Navy started its experiments on radio about the time Marconi gave his first public demonstrations. More than twenty years ago a radio station was installed at the Navy Yard here in Washington. The flag pole of the commandant's house was used to support the antenna, and messages were sent from there to Annapolis, where a flag pole likewise was used to receive. After this, the development went by leaps and bounds.

Our first big radio station, built to communicate with the fleet, was the Arlington station. Like all other developments it took a considerable length of time to get under way. * * *

Long before radio telephone broadcasting became the order of the day, thousands of persons all over the country, as well as ships over the seven seas, received from it time signals and broadcasts. * * * * *

At the present day, radio telephony is considered the ordinary thing. I don't suppose there is a member in the audience tonight who knows that the first modern radio telephone broadcast was transmitted from our station at Arlington as long ago as 1915. This broadcasting has not been the result of one brilliant idea by some genius; it has been developed step by step through laborious investigation and experiment. In 1915 the radio messages broadcast by Arlington were picked up in Paris on the one hand and in Honolulu on the other. The success of the experiment largely contributed to the development of the science.

These are only a few striking instances of what the Navy has done for radio from day to day during the past 20 years. We have been selecting, testing, rejecting, and adopting devices in radio work. We cooperated with the General Electric Company in the organization of this Radio Corporation of America from whom this message is going. This is an American company financed by Americans and serving our country. At its head is a splendid American, General Harbord, whom I have known for years and am proud to call my friend.

In view of the close relationship between the Department and the Radio Corporation of America, the Radio Corporation has arranged to turn over to the Navy Department at least once a month its new broadcasting station. On these nights, experienced naval officers will tell the story of the Navy and our band will play for you. We are most anxious to do this, for we know that the more the people in the country understand what the Navy means to them, the stronger will be their support of it.

Abstract of an address made at the opening of Station WRC, Washington, D. C.

No Static Above 3,000 Feet, Balloonist Reports

By C. D. Wagoner

STATIC, that mysterious interference to the reception of radio signals which is perhaps one of the greatest puzzles to radio experts today, may be confined to an atmospheric belt about the earth. At least that is the possible conclusion reached in special tests made by Ralph Upson, one of the country's most prominent aircraft engineers who was a contestant in the national balloon race which started from Indianapolis last month.

Upson's balloon was equipped with a powerful lightweight radio set by the General Electric Company. For six weeks preceding the race Upson had used the set in his home and thereby became thoroughly familiar with its operation under various conditions. His experience had taught him what static sounded like and he also learned that the air seemed particularly filled with it when there was an electrical storm in the vicinity, so much so in fact that one of the uses he planned for his radio outfit in the race was to detect thunder storms before the lightning might be visible.

In his tentative report to the General Electric Company made after the race, Upson writes:

"One of the outstanding happenings in the use of radio in the balloon race was that at altitudes of 3,000 feet and above we observed absolutely no static whatever, although we could see lightning at various points on the horizon."

Upson's chief purpose of carrying radio was to help him win the race. Five of the principal broadcast stations had arranged to send out special weather reports on upper air currents during the first night of the race and the following morning. In regard to this Upson says:

"Andrus, my aide, acted as chief radio operator. He began listening in at 8:30 o'clock the night of the race. At first he could hear nothing but code signals, concerts from various stations and a radio drama that was being sent from a Chicago station. For an hour this was about all we could hear. Then at 9:45 o'clock, Central time, Andrus picked up the latter part of the weather report being broadcast from WGY in Schenectady. We heard just enough of it to make us wish we had heard the entire report. However, our disappointment was short for a few moments later the whole report was repeated, every word being received clear and distinct. It was just the news we wanted.

"As a result of the information, we decided to go a little higher but not to try any high altitudes unless forced to it by thunder storms. The report gave us full confidence of reaching New York State and possibly New England. Everything seemed so favorable that I turned in to sleep, leaving the balloon appendix partially closed. Then came the accident and you know the rest, a forced landing."

Omit the Condensers

A LOT of trouble in summer time receiving is caused by the use of series condensers in the antenna and ground circuit of the receiver. Do not use them unless it is absolutely necessary. They collect atmospheric charges and cause louder and more clicks and bangs.

Digitized by Google

A Portable Set for the Hike

By Kenneth Malcolm, A. I. R. E.

THE portable set to be described is very small and light of weight; and yet it is not a freak set as many small sets are, but employs a standard circuit that, within its limits, will give very good results.

It is trusted that all good bugs have a fair idea about radio, and are somewhat familiar with the apparatus used and its construction. So, therefore, only an outline will be given—leaving the drawings to do the rest. The measurements are only suggestive, and need not be strictly adhered to, except in the case of the number of turns on coils and the capacity of the condenser.

The apparatus needed includes a .0005 mfd. variable condenser of one of the new flat types having a mica dielectric; two fibre disks about 1/32 inch thick and 3½ inches in diameter; 40 feet of No. 22 single cotton-covered wire, and 70 feet of No. 24; a rotary switch

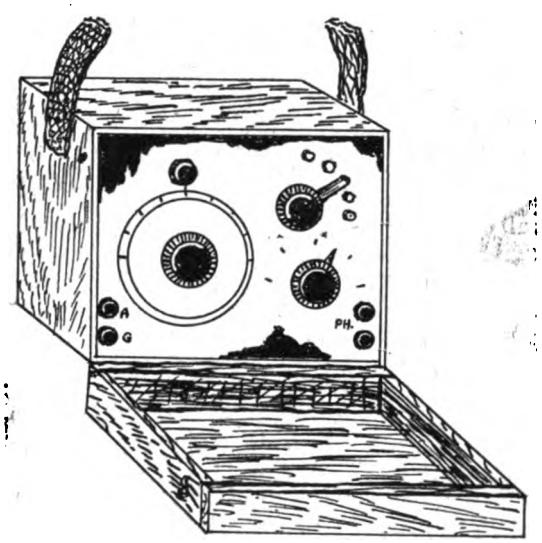

Fig. 1. View of the portable tube receiver as it should appear when completed.

arm and five contact points; a vacuum tube and socket; rheostat; grid leak and grid condenser; four binding posts; a short length of 1/16-inch brass strip and ⅛-inch round brass rod; a panel and cabinet; a small insulating knob; and the necessary aerial wire, batteries and phones.

The inside dimensions of the cabinet should be six inches wide, four inches deep, and five inches high. The hinged cover should have an inside depth sufficient to allow for the height of the knobs and dials. A panel of bakelite or some other good insulating substance about 3/16 inch thick, and a size that will fit the front of the cabinet, should be secured.

There are on the market several .0005 mfd. tuning condensers that have a mica dielectric and are very thin that would do very well for this set. However, a standard condenser may be used if the depth of the cabinet is increased. The mounting of the instruments on the panel should be done as the drawings show—the condenser on the left side, and the rheostat and the switch on the right. A little hole is drilled directly over the condenser dial, through which a ⅛-inch rod will pass freely.

The tube to be used depends upon your individual taste, though for a portable set the dry cell type is the only one that is practical. The WD-11 that operates on a single dry cell, and the UV-199 that will operate on a three cell flashlight battery, are both very suitable. The first mentioned tube requires a rheostat having a resistance of about six ohms, and the latter a rheostat of about 30 ohms.

The grid condenser should have a capacity somewhere between .00025 and .0005 mfds, and should pref-

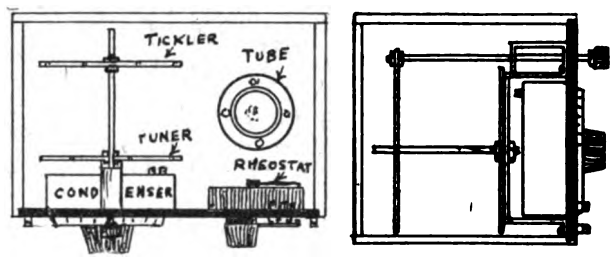

Fig. 2. Top and side views of the set showing the location of the various units and parts.

erably be of the mica dielectric type. The grid leak should best be variable, unless you have a number of different sizes that you could first experiment with, to find the correct resistance.

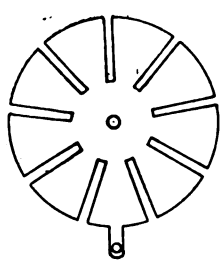

Fig. 3. Details of the spiderweb former used as an inductance.

Next, the coils may be made. Each disk should be cut with slits about ⅛-inch wide, so that there will be nine "wings" on each. In the center of each disk should be drilled a ⅛-inch hole, and one disk should have a projecting lug left on one of the "wings," about a half inch long, and drilled near its end with a ⅛-inch hole. This disk with the lug should be wound spiderweb fashion with 75 turns of the No. 24 wire; that is, the wire should be passed over one wing and under the next, and so on. The other disk should be wound by the same method with 45 turns of the No. 22 wire. This latter coil acts as the tuning inductance and the first coil as a tickler, for the purpose of regeneration, or for the receiving of C. W.

The coil used for tuning may be mounted on the back of the panel by means of a strip of brass, bent as

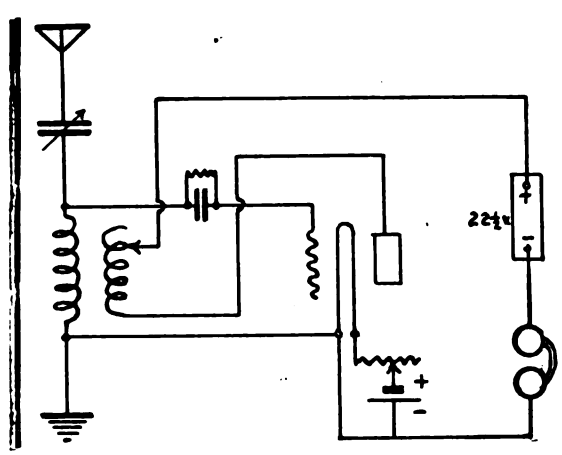

Fig. 4. Circuit diagram of the portable receiver. It is the conventional single circuit diagram. Care should be taken in the construction if success is desired, paying particular attention to the polarity of the battery leads.

shown. It will be observed that the upper end of the strip is bent up, back and down again, to form a sort of a bearing for the tickler adjusting rod. A length of

Amateurs Relay Naval Radio Messages

SPRINGFIELD, MASS.—Radio amateurs residing in this city are giving their services voluntarily in the First Naval District by relaying official messages requiring prompt attention, between the Reserve Division here and the Brigade Headquarters at Boston. Commander J. T. Nelson, in a recent letter addressed to Ensign H. F. Johnson, of Springfield, commended this work in these terms:

"The work of your division in training men for radio operators is greatly appreciated and your division is the only unit where training of this nature is being carried on. It is the brigade commander's wish that you continue this work and expand this radio department if it can be done without detracting from the general training of your division."

This practice under service conditions is valuable.

Concerning Plate Batteries

THOSE amateurs using dry cell tubes should be glad to get a little information relating to them and the dry cells used for their operation. It is always a good plan to use two dry cells in parallel for every tube used, by so doing the life of the batteries will seem to be everlasting because of the fact that they really do last so long. Six dry cells have operated a three tube set for nearly 7 months and are just now beginning to show a voltage drop after they are in use about 30 minutes in the evening. Which is cheaper, buying six dry cells now and having them last seven or eight months or buying three and having them last one or two?

Important Future for Radio Compass

POSITION finding by wireless is destined to be one of the most important navigational aids of the future, whether employed alone or in conjunction with sound to obtain synchronous signals, according to D. W. Hood, M. Inst., C. E., engineer in chief to the Corporation of Trinity House, London, who was among those present at the International Congress of Navigation, held in London last month. George R. Putnam, Commissioner of Lighthouses, was among the American delegates to the convention, which was declared to be the most important meeting of the kind ever held.

In his report, Mr. Hood referred to the fact that various countries have different direction-finding systems of their own, and recommended that an investigation be made to find the most effective method, not by individual countries but by one agency under an international agreement.

The establishment of radio fog signals was the most important advance in lighthouse work in the United States during the past ten years, according to a paper read at the conference by Commissioner Putnam. The first of these signals were placed in service on May 1, 1921, when three were put into commission in the vicinity of New York harbor. The number of such stations has been increased during the past year.

Each of the radio fog stations in United States waters sends automatically during fog or low visibility radio signals on a wave length of 1,000 meters, with a distinctive characteristic, which are used by vessels equipped with radio compasses. Very reliable results are being obtained, Mr. Putnam declared.

(*Concluded from preceding page*)

the brass rod is cut, sufficient to reach from the tuning coil to the back of the cabinet. This is threaded at one end, and fastened securely to the tuning coil by means of nuts and washers. The other end is left free. Another length of rod is cut, sufficient to reach from the face of the panel to the back of the cabinet. Both ends of this are threaded for a short distance, and on the end that projects through the panel the small knob is fitted. After the tickler coil has been slipped over the center rod, the other end is fastened with nuts to the lug on the tickler. This allows the coupling between the two coils to be easily varied.

The tickler should be tapped at 55, 60, 65, 70 and 75 turns, and flexible leads should be carried over to the five switch points on the panel. The remainder of the wiring should be done with rather stiff wire, and it is imperative that all joints be soldered. The tube is mounted either on the base of the cabinet, or upon a sub-base attached to the panel—the latter is more satisfactory. The A and B battery leads may be brought to binding posts, or the batteries may be included in the cabinet by increasing its size. The aerial and ground binding posts are mounted in the lower left hand corner of the panel, and the phone posts on the lower right.

The aerial for the hiker could best be of flexible insulated lamp-cord, in a hundred foot length. A stone could be attached to end of this and flung over the limb of a tree. A ground is more difficult to get in the open, but might consist of a counterpoise of a wire similar to the aerial wire strung out on the ground, or a long length of wire thrown in a lake, or buried in the bed of a stream. Old pumps and wire fences sometimes make good grounds. If it is large enough, the aerial and ground wires might be coiled inside of the cover when carrying.

To operate the set, begin by turning on the rheostat to some arbitrary point; next adjust the variable condenser until a station is heard; then vary the tickler coupling and adjust the switch until maximum response is obtained; a re-adjustment of the rheostat will now give the best results.

If a strap of leather or webbing is attached to the cabinet, it may be carried about as easily as a canteen of water.

The Radio Woman

SEVERAL of our friends who had not succumbed to the radio fever had been coming to our club every Thursday evening. It used to be that our Thursday nights were bridge nights, then Pung Chow, but both have been relegated to the things of the past. In their place we now have a "Radio Fest." That is, we used to have but one by one, the outsiders were prevailed upon to buy sets, and the recent sales by department stores of real sets at small prices have stolen most of our "club" from us. But just the same, we take great pleasure in comparing the working of our different sets on different nights, and F. H. says that going down to business in the morning, even the conventional poker or pinochle game has been stopped in order to compare notes on the evening before reception. "I am sure that if radio has done nothing else, it has developed more liars than golf ever did. Jack can be relied upon to keep quiet until everyone has told of his performances, and then he brings out a slip that he supposedly copied the night before and stops us all. Some of these nights I am going to drop in unexpectedly, when I know his storage battery is charged and everything including static is favorable to distance, and see just what he does or says when he has a witness."

Well, I believe that a little stretching now and then keeps the interest up, inasmuch as it makes the other fellows sceptical, and then again radio reception is such a freaky thing that anything is possible, even KYW on a crystal.

* * *

Which, by the way, reminds me that I received a letter from a little girl out in Wyoming addressed to me at RADIO WORLD, and wanting to know if I thought that it was in my opinion wrong for a little girl to "play with big brother's radio." It seems that she has become quite a fan and, of course, quite adept at the manipulation of Bob's radio set, but that he disapproved of it and kept telling her to "Keep your hands off, and play with your dolls." She asks me if I think that it is wrong for her to "listen in" if she knows how to work the set.

Well, Mae dear, all I can say is that I think that Bob is very selfish. I should think he would be glad to let you show that you are able to operate such an intricate mechanism as a four tube set. Girls these days are not the little wall flowers and feminine frailties that they used to be considered, and you just tell Bob that both F. H. and myself think that he is selfish.

* * *

Another thing that must be of interest to fans is this. I have noticed on several of the cooler days that reception during the early part of the evening will be remarkable. No static, or any other phenomenon. Even WGY will not fade quite as often or as much as usual. Then suddenly around 11 or 12 o'clock, static will start to rumble and crack and spit, and stations will start to fade in and out with unseeming regularity. And nine times out of ten, the next day will be a bright, sunshiny warm day. I have noticed this for some time, and one fact especially is that on an evening when there was a lot of static, there were generally clouds in the sky, and the next morning the sky would be absolutely cloudless.

Watch these little things, and then you will begin to wonder. I have a faint suspicion that the clouds moving through the air have some bearing upon the static, but, of course, I am not up on it as a radio engineer, but I am entitled to my opinion, and now you have it.

WCAP Does Stunts

NEW radio history is being made daily by the Chesapeake & Potomac Telephone Station (WCAP) in Washington, D. C. As yet, no local programs have been put out by this station, which has confined itself to the broadcasting of the programs of WEAF, New York, received in Washington over a special land line, and there "put on the air." However, the Washington station made arrangements whereby the concerts of the famous Marine Band were picked up at whatever point the band was located by means of a special automobile truck, equipped with microphones, controls, etc., from which the music was sent to the transmitting station by tapping in on the nearest telephone cable.

So successful did this method of pick-up prove that concerts by the Marine Band were sent to New York over the line usually used for the reception in Washington of New York entertainment, and broadcast by WEAF. The same system was followed when the memorial services held in Washington churches for the late President Harding were broadcast both from WCAP in Washington and WEAF in New York. The truck used by WCAP has practically all the equipment of a Class B station.

Mrs. Coolidge Has Her Own Private Radio Set

(C. Underwood and Underwood)

Mrs. Calvin Coolidge, wife of the President of the United States, enjoying a few spare moments listening in on her private radio set. Mrs. Coolidge is a keen follower of radio, and is well versed in its possibilities. Radio has interest for everybody that is interested in life, because over it one may hear classical music, interesting talks—in fact anything and everything that is of value to the men and women of today. That is why it appeals to "the first lady of the land."

"Save the Juice!"

THIS is an expression used in the studios where they make motion pictures whenever they have finished taking a scene and the huge arc and Cooper-Hewitts are not needed. It can be used successfully by the average radio fan. It is not necessary to use the loud speaker for local work when you are just entertaining yourself or two or three other people. Use your phones on the detector and get better and clearer reception—and "save the juice!"

President Harding Was a Good Friend of Radio

By Carl H. Butman

WASHINGTON, D. C.—The important part played in our daily life by radio was forcibly impressed upon the public when, following the death of President Harding, a majority of the broadcasting stations throughout the country closed down for varying periods as a mark of respect.

The almost complete cessation of broadcasting brought home as could nothing else the important niche which radio has carved out for itself in our daily routine in the past two years. People in all walks of life commented upon the gap in their evenings, which they found hard to fill, and while practically all agreed that it was but fitting that the broadcasting of entertainment should temporarily halt while the country sorrowed, probably nothing else connected with the final honoring of our dead President made as deep an impression.

In the death of President Harding, radio lost a good friend. He was one of the first officials of the Government to turn radio fan when, following the first radio conference in 1922, the attention of the country was turned toward the new method of entertainment. The set built for his use in the White House was the last word in reception but, while he liked to "play" with it, he had but little time to devote to amusement and found himself for a long time unable to cope with the interference which prevailed when there was but one wave length for broadcasting.

In many ways the President evinced his interest in radio. He gladly accepted the invitation extended to him by the National Press Club of Washington to attend the exercises incident to the "christening" of its receiving set, and while the music and speeches which were to have been broadcast from a nearby government station especially for the occasion failed to "come through" the President "stuck around" like the "good fellow" he always was, chatted with the members of the club—which is composed of newspaper men—and made them a little talk on the difficulties of being President which gave them much inside dope on the great task which confronts the nation's Chief Executive from day to day.

While the failure of Congress to pass the White Radio Bill kept radio from becoming an official subject of consideration at the White House, Mr. Harding frequently expressed his interest in the matter and the hope that legislation could be enacted to eliminate interference, give the amateurs the privileges they desired and which he thought they were entitled to, and put radio on a concrete foundation.

President Harding was radio's friend, and the silencing of the broadcasting stations of the country was but a fitting mark of respect to a man who laid down his life for his country as surely as if he had died on the field of battle. No finer tribute could have been paid than the silencing of more than 500 stations, quiet while the country ceased its activities and a hundred million people mourned.

Radio Serves in Peace and War

By Major General John L. Hines

Deputy Chief of Staff, United States Army

THE progress of civilization depends, in a material sense, upon the advances made in the technique of transportation and communication. These are the links which bind us into a social organization. This station alone will have a great influence in maintaining social unity in America in the face of the disintegrating effect of the rapidity with which we are beginning to move and to live. Its facilities will be a tremendous factor in commerce and industry. * * * All of this makes it apparent that such an undertaking is not a private concern but rather a public utility in the widest sense of application. Lending itself to the improvement of our unity, during peace time, it is equally suited to protect that unity and the public interest when our peace is threatened. * * * * *

It is comforting to realize that in any future eventuality we would have the use of such agencies as this station. It is not too much to say that these facilities would bring the people of our great country as closely under common guidance as were the Minute Men of Lexington when they were mustered by the single efforts of Paul Revere. * * * * *

Typical of good Americanism is this action of the Radio Corporation of America in opening for public use an implement which it intends and hopes will be used for peaceful progress but which it would gladly turn over to our country for use in resisting wrongful aggression against our rights or our ideals.

I believe that many thousands of Americans will receive enjoyment from this agency. I trust that it will add to our great progress in civilization and that it need never be used to marshal our forces for defense. Above all, however, I hope that it will serve as an additional bond to strengthen that spiritual Americanism that is one of the most potent forces for good in the world today. * * *

Abstract of an address made at the opening of Station WRC, Washington, D. C.

Not Necessary—But Handy

VERY few of the home constructed sets have more apparatus than is actually necessary for the reception of signals. However, an added refinement, and one that will prove a valuable asset to the operator once he gets on to the hang of its use, is a plate milliameter. Many times a set will function fine one night and suddenly the very next night be "out" and you go hunting for trouble where there is none. If you include a small plate milliameter in the set (it doesn't have to be an expensive one) you can have an accurate check on your battery by means of its variations. Some interesting facts will be noted also on the amount of current passing through the plate circuit in different distance work. Some stations will pass as much current as .5, while some locals, though much louder, will only pass .6.

California High School Installs Sending and Receiving Radio Station

By Charles Geiger

THE firm hold which radio has taken upon the people has made it necessary that instruction in this art be given in a complete manner, and in order that the instruction at the Piedmont High School in Oakland, California, should be properly demonstrated, the Board of Education has installed a radio sending and receiving set. This is complete in every detail and is unique in the fact that it is mounted entirely in an ordinary office desk.

To the right of the desk, and let into the top, is the amplifier. The center drawer and the drawers in the right hand leg of the desk are left intact for the storage of the apparatus and spare parts for the radio set and for instruction material, while the left leg has been converted into two compartments. The door to the left front is arranged to resemble the drawers, so that the general appearance of the desk is not disturbed. In the front compartment is mounted the motor-generator for supplying the plate voltage to the sending part of the set, and there is also mounted in this compartment the switchboard controlling the charging and discharging of the storage batteries. The second compartment, directly behind the first, entrance to which is by means of a door on the left hand side of the desk, is lead lined, and in this are placed the storage batteries.

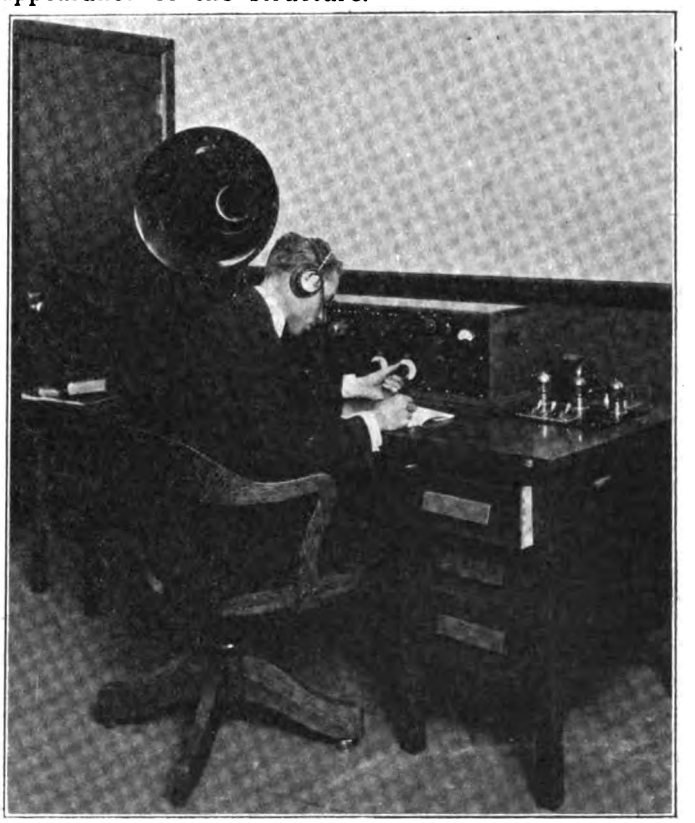
Mounted on top at the right of the cabinet, is the chopper, used in sending code or telegraph signals. The sending key is portable and mounted on an insulating base with long, flexible leads, so that it may be placed at the convenience of the operator or student. The set embraces a fully equipped receiving set for reception of all kinds up to 600 meters; it includes a small broadcasting station on which both voice and music may be sent by radio telephone; it has the key and equipment for sending by code; it has the three types of tubes—detector, amplifier, and transmitter—and therefore provides equipment complete for instruction in the art of radio.

The wiring is all concealed and presents a compact, neat appearance. The current supply is brought from the main switchboard of the school directly to the convenience outlet in the chairboard of the radio room.

Another unique feature of this installation is its equipment of standard convenience outlets, which are placed along the back and let into the top of the desk. The two on top are the connections for the Magnavox and permit it to be placed at any desired distance in the room or the adjacent room. The other convenience outlets are for the direct current battery terminal, the alternating current terminal to the rectifier for the charging of the storage battery, the ground connection and the alternating current mains used for the operation of the motor-generator and the chopper.

The recharging equipment is located in the closet just off the radio room, so that the noise and vibration will not disturb the receiving or transmission of messages. In addition, it is mounted on thick cork to in a measure deaden the sound.

The antenna is located on the roof and is so arranged that the artistic trimming of the building masks it from view. One pole extends only ten feet above the roof, and it is set into a socket composed of a piece of 8" steel pipe securely fastened to the concrete structure and guyed against movement in any direction. This socket provides a means of effectually making water-tight the opening through the roof, and also securely holding the pole in place. The other pole is secured in the corner of the concrete structure in the rear of the building. Both poles are turned and artistically capped. They are painted the same color as the building, and add to rather than mar the general appearance of the structure.



Radio sending and receiving set designed and built for the Piedmont High School. The apparatus is installed in an ordinary office desk.

The set and installation were made by the engineers of the Atlantic-Pacific Radio Supplies Company, Inc., of San Francisco, under specifications from the office of W. H. Weeks, architect for the Board of Education of the Piedmont High School, Oakland.

Another installation is a method of communication between the superintendent's office and each of the class rooms. This is designed and manufactured by the Magnavox Company and is known as the "general announcing system." There is installed in each room a "telemegafone," of which a duplicate is located in the superintendent's office. A selector panel provides a control arrangement by means of which the superintendent may at will talk to any one room or to any number of rooms.

An additional installation entirely new and unique is the combination of this announcing system with the radio receiving equipment. A special line has been run from the radio receiving set in the radio room and connected to the selector panel, by means of which the superintendent is enabled to divert the radio messages into any particular room or into any group of rooms which he may select. The arrangement is such that it is possible to have the "telemegafone" in any one room or every room working by radio at the same time.

Uses and Abuses of the Dry Cell

By Velma Carson

ABOUT the time the farmer radio fan has invited some of the neighbors in to hear the fight returns and the lecture by Bryan, he finds that he can't tune in. Or if he tunes in at all, he gets a noise that sounds like a mouse whispering. The old thing simply won't show off. And he feels like the mother who has asked her precocious youngster to play "Humoresque" while the Ladies' Aid is meeting with her and never even gets the wretched, sulky child out from behind the door.

He explains apologetically that the battery must be worn out. Before he can get to town to have it recharged, the fight returns are in the newspapers and Bryan has traveled 900 miles to the next audience. The battery slips up on him this way about once every two months. In three years, beyond all coaxing, it gives its last, and dies a natural death. In the meantime, he has given it about $36 worth of rejuvenation which, added to the original price of $15, makes a total of $51. This does not include the loss, possibly, of a piece of the living room carpet eaten up by some spilled acid.

A dry cell either performs or it doesn't. If it doesn t, all the farmer has to do is to take it to the door and throw it as far as he can, and reach in to a reserve supply of them and get out another. You buy them like you do cigars. The dry cells cost 35 cents each, last for a hundred hours, and will keep unused in good condition for more than six months. For $51 one can purchase a ten years' supply. There is nothing in them that could possibly spill. They are what they say they are—dry cells. The dry cell can be carried around in a coat pocket, being only 2½" in diameter and 6" high. It is the only kind to use if the receiving outfit is to be taken on trips or carried from one room to another.

But there are several important things to remember in connection with the use of dry cells. One of them is not to burn the filament out by using the set continuously. Luckily, though, the broadcasting stations never accommodate such a desire. Just so the listener does not forget to turn the set off when the concert is over, this is not likely to happen. And it is important to not run more than one tube from one cell. If you have two tubes, use two cells in parallel. When possible use two cells in parallel to supply one tube. One point to be remembered when connecting cells in parallel is not to use an old and a new cell. Their voltages will be different and will set up local circulating current which will soon spoil the new one and will not improve the old one.

Safeguard Your Set

HOW many of you owning receivers have neglected to install lightning protectors? Do not run any chances with fate or lightning by neglecting this little item. It is only one chance in several million that it will ever be called upon to protect your set—but it's no use to lock the barn door after the horse is stolen.

More Broadcasters

DURING the past week three more broadcasting stations were licensed by the Department, as follows:

Call	Station	Class	Frequency Kcys	Wave Lgth Meters	Power Watts
KFJK	Delano Radio & Elect. Co., Bristow, Okla.	"A"	1290	233	100
WTAF	Gallo, Louis J., New Orleans, La.	"A"	1240	242	20
KFBC	Nielson Radio Supply Co., Phoenix, Ariz.	"A"	1260	238	10

W J A J	Y. M. C. A., Dayton, Ohio

Changes in Licenses

One new broadcaster and six transfers from Class C to Class A have been announced by the Department of Commerce, all in the western half of the country. The new broadcasting station is that of the Hardsocg Manufacturing Co., Ottumwa, Iowa, which has been given the call KFJL. This is a Class A station, having a wave length of 242 meters (frequency, 1240 kilocycles), of ten watts power. The recent transfers from Class C to Class A are as follows:

Call	Station	Class	Frequency Kcys.	Wave L'gth Meters	Power, Watts
K F C B	Azbill, W. K., San Diego, Calif.	A	1080	278	20
K F C K	Colorado Springs Radio Co., Colo. Springs, Col.	A	1240	242	10
K F B K	Kimball Upson Co., Sacramento, Cal.	A	1060	283	100
K F A W	Radio Den, Santa Ana, Calif.	"A"	1070	280	10
K N V	Radio Sup. Co. of Calif., Los Angeles, Calif.	"A"	1170	256	20
K D P T	Southern Electrical Co., San Diego, Calif.	"A"	1230	244	50

Think This Over

MANUFACTURED sets are made by experts. Therefore, if anything should go wrong with your set, unless you are accustomed to fixing it, it is best to take it to the manufacturer or the manufacturer's agent and let him analyze the trouble.

Another "Neutro-Generative" Circuit

By C. White, Consulting Engineer

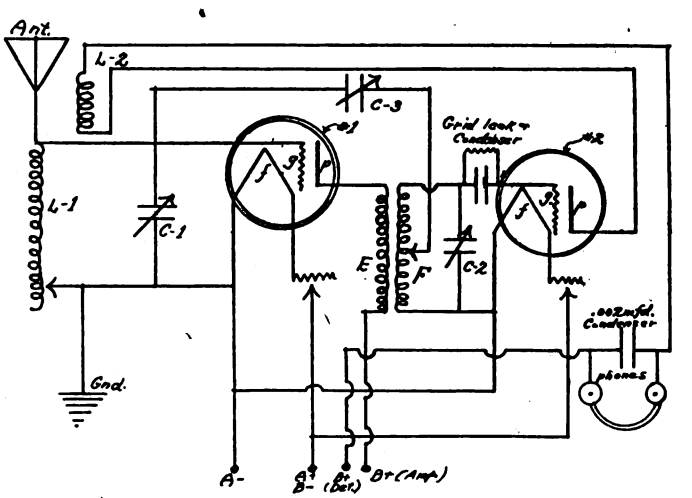
IN every radio fan there is the instinct and initiative to try the new. We are never satisfied fully with what we already have, and it is very good for us that we are not, because it is that spirit of perpetual search for something better that always leads to something better. Yet we are not all fully equipped to carry on a large amount of experimental work even if we should find the time. New circuits often mean new parts and apparatus which means more money to be spent. But it is often possible to try out a new circuit by using most of the apparatus already on hand. Nearly every radio amateur has a good variocoupler, several condensers and miscellaneous other tube accessories; hence, if he can only arrange what he already possesses and purchase just a few new items he is readily in a position to experiment. There is hardly a man who has a radio set that is not eager to try out some of the underlying principles of the "neutrodyne" in connection with his present regenerative receiver. Excellent results are easily obtainable for those who have the patience to fuss around the circuit until they get it balanced and working in good order.

The circuit illustrated is nothing more than a simplification of a previous "neutro-generative" circuit. (See RADIO WORLD, August 18, 1923.) It has been expressly designed for those who do not feel inclined to go to the extra expense to purchase choke coils, telephone size condensers, and extra potentiometers. In brief, it is a hook-up for the man who wants to try out first without heavy expense. Of course the previous "neutro-generative" receiver is the better one owing to the fact that more controls afford easier and more flexible stabilizing adjustments, but this receiver will operate satisfactorily just the same and afterwards the extra controls can be added. Audio-frequency amplification can be added to this receiver, if it is so desired, to increase the volume for the use of loud speakers. The stage of radio-frequency will not increase the volume of local stations very much over the volume obtainable with the detector tube alone, but it will enable a large number of relatively distant stations to be brought in with the same volume as the local stations, and quite a number of very distant stations that were never heard before.

In order to keep down noise it is advised that a very short aerial be used. This not only means less static, but also far better selectivity between stations. I firmly believe that many amateur aerials are entirely too long and act as wonderful static collectors in the warm weather. Try shortening your aerial a little and notice the difference in static as well as signal strength. There is a certain balancing point in length where the best possible signal volume and clarity is obtained.

The constants for the circuit are as follows: The unit L-1 and L-2 is an ordinary variocoupler using the coil L-2 as the rotor, C-1 and C-2 are each 11 plate condensers, but if you have on hand two 23 plate condensers they can be used instead of purchasing new ones. The condenser C-3 is a *very small* two plate vernier used as a stabilizing condenser which controls oscillation and by its proper adjustment oscillation can be avoided over the entire wave range of the set. The unit E-F is the only special thing about the circuit. The coil E is wound with No. 22 S. C. C. magnet wire on 3½" tubing, having 60 turns in all. The coil F is similar, only being wound on 4" tubing and tapped for switch points at each tenth turn. In the complete assembly of the unit E-F the coil E is placed inside of the coil F, thus rigidly fixing the coupling. If you fail to obtain an increase in volume as the coupling between L-1 and L-2 is increased, reverse the terminal connections to the coil L-2. Body capacity will give little or no trouble if the condensers are connected in as advised. The fixed plates of the condenser C-1 and C-3 are to be placed nearest the grid of tube No. 1, and the fixed plates of C-2 are attached to the grid side of F. In this way grid potential is removed from the shaft or movable plates of the tuning condensers and there is no howl as the hands are brought near the capacities for adjustment. To further cut down the little body capacity effect that remains, a small circular sheet of copper foil can be attached to the panel in front of each condenser. These shields should be connected to the ground terminal of the outfit. It is foolish to use too much copper foil for it would be of no particular avail.

Try this circuit if you can because it requires only one special part, the coil E-F, which can be easily made at home, and you will find you have a set that will operate on an extremely short aerial, thus making a small indoor or portable aerial feasible.



Simplification of the "neutro-generative" circuit described by Mr. White in RADIO WORLD for August 18, 1923.

Do You Yell?

WHEN talking to a friend over the telephone, do you yell? Then why burn your tubes up to their maximum when receiving? By doing this you are producing innumerable troubles for your neighbors and consequently causing them to bless you in no uncertain language—and you are not getting anything more out of your set than you would if you lowered the voltage and tuned your set properly. It is a mark of "amateurishness" to burn your tubes as brightly as they will, and it is also a blessing to the other fellows who are just as interested in radio as you are, when you shut off for the night. Conserve your tubes, their tempers and your signals by learning how to get maximum signals by the use of minimum filament current.

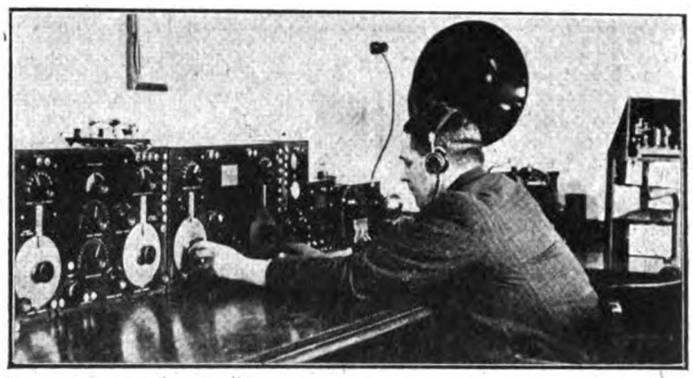
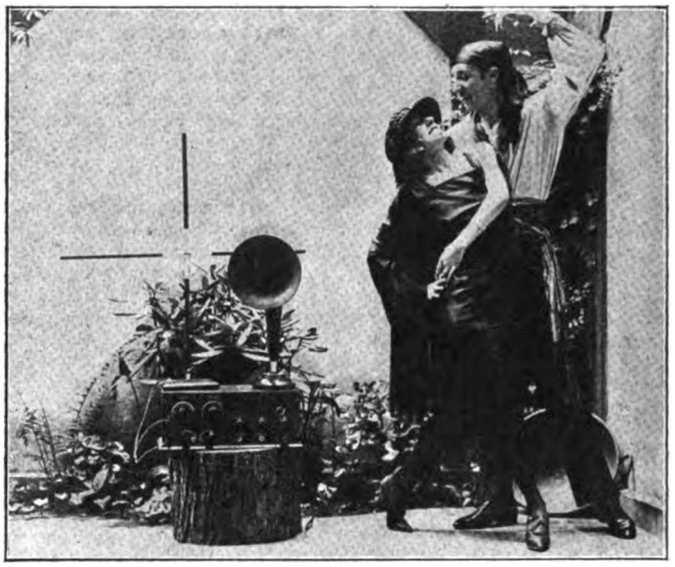
Note the apparatus on the left, showing the cali- ine is a complete receiver and transmitter, capable of being wind-driven generator. Each machine has six tubes, and of the triple pole double switch seen directly under the bank sion, simplifying matters considerably. Note also the jacks, only be inserted in the right manner, due to the slots cut a cer- making it a wonderfully compact but at the same time mar- le instrument.

(C. Kadel and Herbert)
The radio room at the supply base of the U. S. Naval Reserve which is used for inter-fleet communication between the eagle boats and the supply base of the naval forces. Chief Radio Officer Harold Cook at the Western Electric 9-36 transmitter. This is a popular type of transmitter on the destroyers and smaller boats because of its ease of operation and its power.



(C. International Newsreel)
The interior of the radio station maintained by the U. S. Shipping Board at Bush House, London. This is one of the most powerful stations in England, as communication clear across the Atlantic is an every day occurence. Constant communication with Annapolis and Panama are assured due to the powerful tranamitters and latest type hetrodyne receivers, but, of course, on the longer wave lengths.



(C. Kadel and Herbert)
Addison and Fowler have taken advantage of the free jazz music over the radio to practice their tangoes. They are shown in one of the difficult steps in their original dance, "Old Madrid," in the Venetian garden of Miss Fowler's Long Island home to the tune of "La Paloma" received on their three-tube loop receiver.

(C. Kadel and Herbert)
Miss Anna Louise Kadel listening in on the lawn to some of the broadcast tales. By the look of the "pup" they must be telling bedtime stories, or else giving a talk upon "how to hold a mashie correctly and acquiring the correct stance," which, of course, is of little interest to the canine mentality, so Mr. Pup follows his instinct instead and snoozes.

RADIOGRAMS

WORLD NEWS HAPPENINGS BRIEFLY PHRASED FOR OUR BUSY READERS

The late Warren G. Harding was the first President of the United States to talk to the people through a radio microphone, and thus spoke to more persons directly than any other Chief Executive. President Coolidge has already spoken by radio through Station WJZ.

* * *

A radio organization known as the Radio Sociedade do Rio de Janciro has been formed in Rio de Janeiro, and already has more than 100 members. Several influential men of the city are among the officers and directors. It is also announced that a daily broadcasting service will be inaugurated by the Praia Vermelha station.

* * *

Station WGM, Atlanta, Ga., has been donated to Georgia School of Technology, making it one of seventy-eight educational institutions now operating radiophone stations. The power of 500 watts ranks it as one of the most powerful stations in the educational class. The equipment will be used for research work.

* * *

Mrs. Calvin Coolidge, new "First Lady of the Land," is an ardent radio fan, and derives much pleasure from her set, which is a large one of improved type. Mrs. Coolidge for some time has had a set in her room at the New Willard Hotel, used temporarily as a White House following the death of Mr. Harding and the elevation of Calvin Coolidge to the Presidency, and will probably take it with her when President Coolidge takes official possession of the White House.

* * *

A new agreement between the Chinese Government and the Federal Telegraph Company, in conjunction with the Radio Corporation of America, has been signed for the construction of five wireless stations in China. Announcement was made by Richard P. Schwerin, president of the Federal Company, upon his arrival from the Orient at San Francisco last week. The American Legation at Peking later confirmed the news. Two of the five stations will be erected at Shanghai, one of them to be the most powerful in the world. The others will be at Peking, Harbin and Canton. Their aggregate cost will be about $13,500,000.

"Jazz fog" is the descriptive name applied by the neighbors of Col. E. H. R. Green to the programs broadcast every evening from his private radio station at South Dartmouth, Mass.

* * *

On the outskirts of Niagara Falls, N. Y., the city has provided a camping ground for tourists. Over the week-ends the camp numbers several hundred persons, and in the evening after the sightseeing for the day is finished radio equipped automobiles entertain the tired travelers.

* * *

One hundred and fifty children between the ages of 1 and 5 years are playing on the lawns of Tranquillity, the country home of the Israel Orphan Asylum, breathing air free from the heavy heat of the city and romping with a freedom impossible in a city institution. Radio equipment makes it possible for them to listen to bedtime stories and music broadcast from various stations. It is said that Tranquillity is the first institution of its kind to be radio equipped.

* * *

French Ministry of Posts, Telegraphs and Telephones is taking steps to give ships in French ports telephonic connection with land. At present a ship is in touch by wireless with the land until she reaches dock. Then, when only a few yards of water separates her from the shore, she is isolated. This handicap is to be overcome by means of a short submarine cable which will connect the ship with the city telephone system. In a few months passengers arriving at Havre can telephone to friends in Paris before leaving the ship.

* * *

Professor W. De Sitter, a Dutch savant, has propounded the novel theory that the earth is not solid, but built on the order of a trembling ball of jelly. De Sitter bases his theory on observations of wireless. It is frequently observed that there is a difference of several hundredths part of a second in the time of transmission of messages between two fixed points. Hitherto this difference has been ascribed to atmospheric conditions. De Sitter, however, declares the earth is a trembling mass and that the two points moved nearer or further away from each other.

RADIO PRIMER

By Lynn Brooks

INCREASING THE POWER OF YOUR AMPLIFIER—With many circuits an amplifier is necessary in order to get volume in anything outside of local work. The main trouble with such circuits employing two amplifying tubes is that the distortion of voice and music is so bad that it robs the original signal of any vestige of its inherent qualities.

There is one way in which distortion can be removed from amplifying circuits. That is by the employment of a grid "C" battery. As is probably understood, the grid in the amplification circuits should always have a negative potential. The moment a positive charge is allowed to affect the grid, the signals will be distorted.

The proper place for such a battery is in the filament circuit side of the amplifying transformer. For this purpose a single flashlight battery of the No. 751 type will be sufficient. The negative pole should be connected in the grid lead, and the positive in the lead that goes to the filament. A battery such as this will last for six to eight months with ordinary use.

In the second stage of the amplifier, it is best to employ two such batteries connected in series. This will effectively cut out all distortion in the amplifying crcuits and signals will be amplified with all their original characteristics which is something that cannot be said of the majority of home-made amplifiers and even most of the factory-made products. In the case of the factory-made product, this will probably necessitate the breaking of a connection and the soldering in of the battery line, but in any case the advantages of doing it are so many that it overcomes any objections you may have toward rearranging your set.

USE OF CONDENSERS SHUNTING TRANSFORMERS—In many cases builders are mystified because of the fact that some diagrams show condensers across the primary and secondaries of audio-frequency transformers, and other diagrams do not. They therefore do not know whether these capacities can be shunted across all the transformers, whether they are specified or not.

In the case of the high ratio transformers that are sometimes used, the transformer ratio is so high that a condenser across the primary and secondary windings will materially help the amplification. It does not matter whether it is specified or not in the diagram, because simply as a matter of experiment it can be tried, and in ninety-nine cases out of a hundred the results will prove satisfactory.

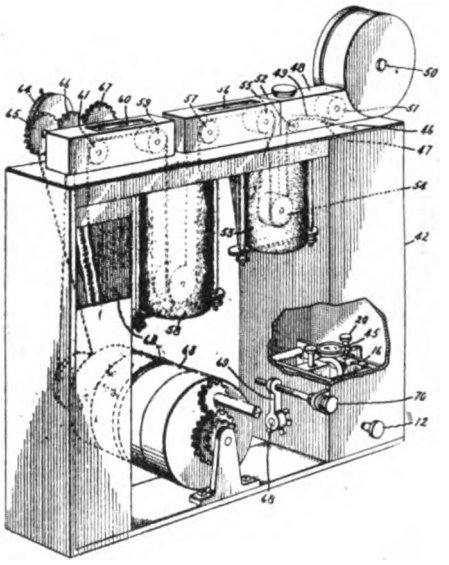
Latest Radio Patents

Recording Apparatus

No. 1,456,595: Patented May 29, 1923. Patentee: Charles A. Hoxie, Schenectady, N. Y.

My present invention relates to an apparatus for and a method of making a record of small electric current impulses and more particularly for recording photographically impulses corresponding to received radio signals.

In receiving radio messages it has been customary heretofore to employ at the receiving station some form of detector which will be acted upon by the high-frequency wave received, in such a way as to produce a current capable of operating an ordinary telephone receiver. The reception of the message has depended upon the ability of the receiving operator to translate the sounds heard by him in the receiver into the characters or letters making up the message. This method has the disadvantage that in case the operator fails to understand any of the



Method of recording slight electrical impulses similar to radio signals, which can be reproduced at will.

letters or words it is necessary to have part of the message repeated in order to make sure that it is correctly received. In case the receiving apparatus is affected by stray impulses or so-called static, which may be of much greater intensity than the signaling impulses, the response in the receiver produced by these stray impulses is so much greater than that produced by the signaling impulses that their effect upon the ear persists even after the stray impulse has passed and the effect of a single stray impulse may be of sufficient duration to prevent the operator from hearing several of the characters of the message. This method of signaling also has the disadvantage that it is physically impossible for an operator to receive messages which are sent at a rate greater than twenty to thirty words per minute.

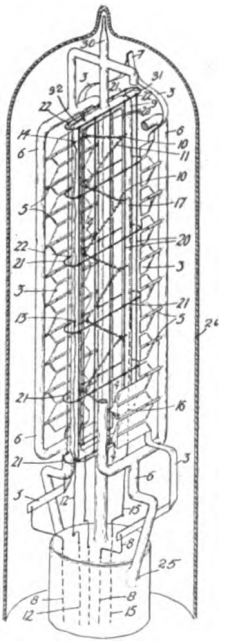
The object of my invention is to provide a receiving system which will overcome the disadvantages above mentioned as well as others. In carrying out my invention I provide means for making an oscillographic record upon a tape, of the signaling current which in the old system acts upon the telephone receiver. The photographic impression upon the tape is automatically developed immediately after it is made and the apparatus so arranged that the message may be read from the photographic record very soon after the record has been made. The apparatus which I provide is also capable of recording messages at a much faster rate than they can be received by ear, the possible speed of the operation being several hundred words per minute instead of twenty to thirty. The effect of stray impulses upon the recording device will last only as long as the impulse itself lasts and will not affect the reception of any of the succeeding characters of the message. Hence a stray impulse, which with audio receiving might obliterate a whole word, may affect only a single letter of the photographic record and not interfere at all with the proper receiving of the message. It will also be apparent that the degree of skill required to read a photographic record of the message will be much less than that required to receive the message by ear.

Arnold's Electric Discharge Device

No. 1,456,528: Patented May 29, 1923. Patentee: Harold D. Arnold, East Orange, N. J.

This invention relates to electric discharge devices and in particular to an improved construction and arrangement of electrodes for the purpose of producing a large current output therefrom.

In designing devices of this type for large current output it is sometimes essential among other things that the tube or vessel enclosing the various electrode elements should be evacuated to as high a degree as possible; a process which involves driving out any gases which may be occluded by the various metallic surfaces within the tube. This can best be done by heating the various electrode elements by some external means during the process of evacuation. Where large electrode surfaces are employed the problem of heating them to a sufficient degress to drive out these occluded gases becomes a matter of some difficulty. This is particularly true in the case of the anode or output electrode, which is customarily in the form of a plate and cannot readily be heated by passing current through it owing to its low resistance and the consequently high currents which would therefore be necessary.



New means of constructing the elements of a three-electrode tube, rendering it easier to exhaust due to the construction allowing heating of anode as well as cathode.

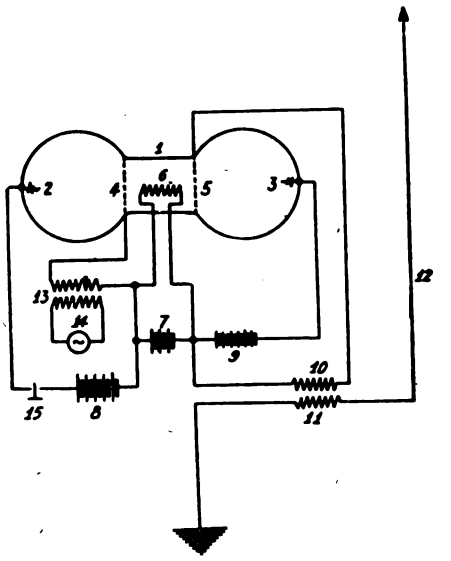
This invention provides an output electrode which is made up of a plurality of bands or strips serially connected and thereby capable of being heated by the passage of an electric current through its length, thus making possible the heating of the anode during the process of evacuation without the employment of unduly high currents.

A further object of this invention is to provide a substantially continuous anode surface composed of a plurality of serially connected sections.

Receiving Arrangement for Wireless Telegraphy

No. 1,454,328: Patented May 8, 1923. Patentee: A. Meissner, Berlin, Germany.

The object of the invention is an improvement on the wireless telegraph



Method of utilizing alternating current to actuate radio transmitter.

receiving arrangement disclosed in German Patent 332,581.

In accordance with the main patent, a cathode relay is actuated by means of an alternating current generator at the receiving station, whereby the received high frequency energy is at the same time transformed and amplified. The changes in the intensity of this alternating current may then be observed by well known means, such as an ordinary telephone. The sound of the local alternating current source may then be heard corresponding to the signal received.

In accordance with the present invention, a particularly advantageous arrangement consists in that the cathode relay is a tube having two anodes and two amplifying grids, whereby one grid is operated by the incoming high frequency, and the other by the alternating current

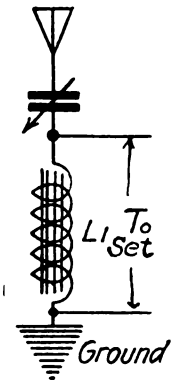
Answers to Readers of Radio World

I have constructed a one tube reflex set and am bothered by the A. C. hum from the lighting circuits. On local stations this hum is not very pronounced, but when tuning for distance it is so noticeable that it drowns out the other stations. This is not due to arc lights as they are not used. The lights go out at 11 P. M. and when they are out everything is fine, but while they are on, the working of the set is almost impossible. Also I get the carrier wave of the station. This is not supposed to be noticeable in reflex sets, but the fact that it oscillates does not seem to hurt reception. What kind of a coupler is best to use with this circuit? Where can I purchase a variocoupler using the honeycomb type winding on both primary and secondary? What type of crystal has been found to work best in reflex circuits? Can you suggest any manner of getting rid of the A. C. hum?—Earl A. Wright, Cole Camp, Mo.

* * *

One method of decreasing the A. C. hum is shown on this page. It consists of about 25 or 30 turns of No. 20 SCC wire wound on an iron core and connected as shown. This will probably cure your troubles. Induction hum in a set of your type is extremely bothersome and just about as hard to get rid of. Another way would be to find out if any light wires run parallel to your antenna and change your antenna so that it runs at right angles to them. The carrier wave you mention is due to your set oscillating. This is common with reflex sets due to feedback through the transformer windings. If it does not seem to hurt your reception it is probably not serious, but suggest that you do not place your transformers in such a position that inter-coupling would be possible. Also do not run your leads parallel. You may use any well made coupler that reaches the desired wave lengths. Apply to your nearest dealer. He can supply you with the information as to where to obtain the coupler you desire. A galena or synthetic crystal is best for reflex reception, using a fine catwhisker and setting the detector proper on a felt or rubber pad.



One method of decreasing the induction hum from nearby light and power lines. It is a choke coil connected across the antenna and ground leads of the set which acts as a frequency choke for the low tension induction.

* * *

Kindly advise me how I can use the enclosed diagram so as to operate a loud speaker. I do not wish to reassemble my set, as it works fine now. What will be necessary?—H. Burroughsford, 54 Parkway Avenue, Toronto, Canada.

A circuit suitable for your use appeared in RADIO WORLD, page 20. If you wish, you can construct this apparatus in a separate cabinet and by using separate batteries for your amplifiers and detector you need not disturb your receiver connections.

* * *

Can I use a 43 plate condenser in a single condenser?—Charles Robertson, 15 Second Street, Lowell, Mass.

Where the diagram calls for an 11 plate condenser, use an 11 plate condenser. If you are just asking for information as to whether a 43 plate condenser can be used in a single circuit—yes, it can.

* * *

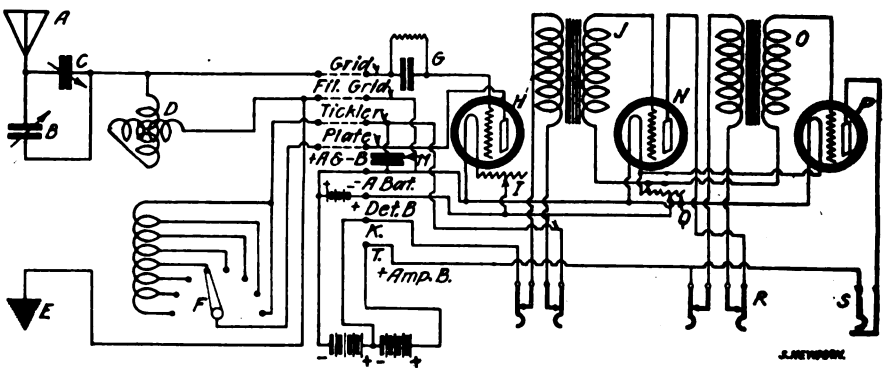
In regard to the crystal set published in RADIO WORLD by Richard B. Wilbur, will you kindly inform me if the beginning and ending of the primary coil are left open or are they brought to taps for the first and last turns?—H. E. Leniback, 1953 Randall Road, Cleveland, Ohio.

The turns you mention are used as the first and last turns of the coil and should be brought to taps.

* * *

Will you kindly furnish me with the circuit diagram used in the Radio Corporation set, the RA with two stages of audio-frequency amplification? — R. D. Campbell, Room 816, 949 Broadway, New York City.

The circuit diagram you wish is published herewith. For your information, the variometer and condenser turn on the same shaft at the same time, both being at maximum or minimum together. The plate coil used for regeneration is preferably wound on the same tube as the stator of the variometer. The regeneration control is governed by the taps on this coil, while the wave length is controlled by the variometer and condenser. A 23 plate vernier condenser is used, with the three plate vernier separate.



Circuit diagram used in the RC and RA-DA combination receivers. A—antenna, B—condenser on same shaft as rotor of variometer, C—3-plate vernier, D—variometer, E—ground, F—tickler wound on same tube as stator of coupler and tapped, G—grid leak and condenser, H—detector tube, I—detector rheostat, J—first audio transformer, K—detector B battery lead, M—condenser across phones, N—first amplifier tube, O—second audio transformer, P—second amplifier tube, Q—amplifier rheostat with tap for grid return of amplifier transformers, R—first stage audio amplifier jack, S—second stage audio amplifier jack, T—amplifier B battery plus tap.

* * *

Kindly give me a suitable circuit for adding two steps of audio-frequency to the Rumford All Wave Universal Receiver described in RADIO WORLD April 7, 1923.—J. A. Beauchamp, Montreal, Canada.

A suitable diagram for this purpose was published in RADIO WORLD August 18, page 20. It is not necessary to reprint the detector circuit as this additional apparatus can be constructed in a separate cabinet connecting it as shown, and just plugged in to the present set, or connected by means of two bridging contacts.

* * *

I have made a four-foot standard for a loop and began at the outer end of each arm and placed 24 small nails one-half inch apart. I began at the inner end of the arm and strung my wire (annunciator bell wire), giving me 24 turns on the loop. Where does the inner end of the loop go? Does it make any difference whether it is strung across the front or back of the wires in order to get it to the receiver? Does the fact that I used wire nails make any difference if the wire is well insulated? Are time?—Charles E. Stevens, M.D., Gogebic Hospital, Bessemer, Mich.

The two ends of the loop go across the variable condenser which is in the first tube circuit. (See RADIO WORLD, July 28, page 13, which will illustrate this.) It makes no difference whether it crosses in front or in back of the loop. The nails should make no difference if the wire is well insulated. Both ends of the loop are used at the same time. When you use a loop it is not necessary to use the coupler, and it should be disconnected from the circuit. The fact that you note a difference in tuning when you use a loop and when you use an outside coupler with antenna and ground is due to the fact that when the change is made, the constants of the circuit proper are changed and therefore the condensers will have to be tuned higher to compensate for the loss of inductance. This does not signify that the circuit is not working properly, so you need not bother looking for trouble where none exists, provided the circuit works properly with both loop and antenna and ground, when each is used separately.

* * *

What causes station WGY to come in strong on my receiver one minute, and then gradually fade away? I have a three-tube set made by the —— Co. and local stations are fine, but on this station and on some of the Philadelphia stations, I cannot seem to keep them tuned in. Is it the fault of my operation, or my set? How should I tune my set to remove this?—James Phelan, Hudson Street, New York.

The "fading" you notice is not the cause of either your tuning or your set. It is very notcieable on the stations you mention. You cannot remove it by tuning your set. The station will "fade" in and out like that continually for some time, and then will settle down to a steady volume for a while only to commence fading again. You cannot stop it.

* * *

In RADIO WORLD, February 10, you describe a set built by E. M. Pace. Kindly give me directions for building a coupler suitable for this receiver.—George K. Menyersen, Chicago, Ill.

For building a coupler suitable for this set, get a 3½" fibre or composition tube, 6" long, and a 3" rotor. On the tube wind 15 turns of No. 22 DCC wire without tapping; then drop the winding down about ½" to allow space for the shafting of the rotor, and wind on 70 turns, tapping each tenth turn, and bringing it out to the switch points as shown. Wind both sides of the rotor full of the same wire

Properly Installed Antenna Greatly Aids Better Reception

ALTHOUGH the receiving sets that are in use among the majority of broadcast listeners to-day will function fairly on even poorly constructed aerials, says a writer in the New York Tribune, it will surely improve matters if the antenna is well designed and the factors which constitute the design are known. The aerial is the source of the energy which directly operates the receiver, and it is obvious that if we can increase the amount of energy collected by the antenna, through judicious design, we can thereby also increase the over-all efficiency of the receiver.

There are more factors entering into the problem of constructing a good aerial than one would imagine from a superficial glance at the subject. These factors include height, length, insulation, grounding, material, proximity to other objects, etc., on the requirements of which a brief resumé will be given.

Height.—It is a well known fact that the higher above the earth's surface one is the greater is the degree of electrification of the atmosphere, varying with local conditions. By way of example an insulated antenna 400 feet high will soon become charged to a potential in the neighborhood of 10,000 volts. This charge has to leak off in some way and will jump small gaps, such as the separation between the plates of the series antenna condenser, in order to get to ground. This produces X's, otherwise known as strays, static and atmospherics. Hence as a rule it is advisable to keep the receiving antenna low, of course, within limits. It has been found that a height of about forty feet is most suitable for good reception. It must be pointed out, however, that strays which come from a distance are not cut down, relative to signals, by using a low aerial. Such discharges are highly damped wave trains and affect the aerial in the manner of an ordinary signal.

Ground.—Since the whole aerial circuit should have a low resistance the ground selected should have as great a surface as possible exposed to the earth. In city districts the best ground is the cold water pipe, it being sometimes desirable to connect both gas and water pipes together for the ground. In country districts several metal plates, about two or three square feet in area, should be imbedded in the ground, surrounded by some charcoal. The plates should be connected to each other by rubber covered wire, soldering the connection. In dry weather the place may be watered, the charcoal retaining the moisture for some time. A type of ground such as this also would be of use as a transmitting ground. The ground wire should be at least of the same size as the lead-in wire and should be short—the shorter the better. The aerial itself should not be more than seventy-five feet in length.

Insulation.—It is of the utmost importance that the insulation of the aerial wires should be nothing but the best if any pretense to efficiency is made. Thoroughly glazed porcelain insulators are the accepted standard for insulation quality, though other materials, such as rubber, bakelite and mica compositions have their adherents. Instead of using one single long insulator it is better to use two or three small ones strung out one after another, as this offers less chance of leakage taking place. The lead-in should be given special attention where it enters the house. Most of the energy losses occur at this point and it does not pay to use the best insulation at the aerial only to lose the carefully hoarded energy by installing a poor lead-in insulator.

Material.—For receiving purposes a single wire is all that need be used. Four wires do not bring in a station better than one. It is a common error to suppose that four wires can pick up four times as much energy as one in receiving. It is true, however, that in transmitting four wires can and do carry a great deal more energy than one. The use of iron wire is not recommended in any form. Instead, use aluminum, copper or phosphor bronze. The lead-in can be made of the same wire, keeping it well away from the side of the building, six feet not being too great a distance by any means. A rather large size of wire should be chosen for the aerial, the thought to increase the surface being the reason for the heavier wire. A small wire is a poor investment for the reason that it corrodes very soon, leaving but a thin core of metal, surrounded by a coating of oxidized matter. This corrosion causes the wire to lose its original strength and, further, the electrical resistance is greatly increased. The latter is the most serious of these two disadvantages. With a heavy wire, or one that is composed of a number of smaller strands, these difficulties are offset for a longer period of time, although they too will not give everlasting service.

Proximity to Other Objects.—If possible the antenna should be stretched over a clear space, free from buildings and trees. It should not be strung in between two tall structures, as then these objects will cut off and screen the passing radio wave. If one end is supported by a tree allow the insulator at that end to extend at least ten feet from the branches. The tie rope or wire only needs to be lengthened to do this. The position of the lead-in has already been touched upon. Keep all wires tightly stretched.

Do not run the aerial parallel to any electric lighting or power line, nor the telephone lines. It is not advisable to get too near any other neighboring antenna either. When in such a position too much interference is apt to result, being caused by the phenomenon of induction.

It will repay you to go over your present aerial installation, keeping the above facts in mind. You will be surprised at the difference that a few changes can make if carried out in all earnestness.

Radio Broadcasting Plant Unharmed by Lightning

IF any further evidence were necessary to prove the safety of radio, there was plenty furnished during a recent severe electrical storm. Lightning entered Station WGI, Medford Hillside, Mass., during the worst of the storm. Investigation showed that it was attracted by the electric light wires, which it completely demolished. The electric light service was paralyzed. However, the 320 ft. steel antenna tower was not touched, nor the powerful broadcasting apparatus, proving that a radio antenna and a receiving or transmitting set does not attract lightning.

Time was when uninformed persons thought the installation of radio provided an extra fire hazard. This belief has been somewhat dispelled by the experts who call the lightning hazard of radio a "childish bugaboo."

Appreciates Our Exposure of Fakes

RADIO WORLD,
Editor:

I am not given to writing to the editors of newspapers and magazines, but your paper has done one thing which is very commendable, and that is the publication of articles relative to spurious radio corporations, etc. Some months ago you published articles regarding the defunct International Radio Corporation, and now your paper carries an article dealing with imitation Brandes 'phones. Fine! It would be better if more magazines did this. It is a public service and one which should be appreciated by the public at large, and the publication that follows this policy should have the support of the public to the fullest extent. You have mine.

*Whatever became of the International Radio Corporation? Might it not be of interest to your readers to state how well this corporation "died"? Several Baltimore "investors" would be interested.

Very truly yours,
M. J. HITCHCOCK.

Baltimore, Md.

*EDITOR'S NOTE: Write to National Radio Chamber of Commerce, 165 Broadway, New York City.

First Radio Mystery Serial from WJZ

SERIAL stories are a well-known feature of magazines, but as items of radio programs they are practically unknown as yet. Doubleday Page and Company believe that the idea is practical—WJZ thinks it is—and from now on the radio audience will have a chance to decide the question every Thursday evening as long as "The Waddington Cipher," a Doubleday Page publication, runs. Just what the listeners will think of the radio serial is an interesting question—it is a new departure in programs, and the reception of new departures is always a matter of interest.

Radio Trade Notes

The Radio Electric Shop, 421 East 31st St., Kansas City, Mo., has entered the retail radio business.

* * *

* * *

The Van Blaricom Co., Helena, Montana, are in the market for cartons for shipping goods.

Daily Newspapers Publishing Radio News and Programs

AS a part of its service to readers RADIO WORLD publishes herewith the names of daily newspapers which carry radio programs and radio news. Wherever possible the name of the radio editor of the paper is given. Additions to the list will be published as received.

Morning Oregonian, Portland, Oregon. Publishes daily radio programs of its own Class B station, KGW, and other Pacific Coast stations, and on Sunday a complete page of technical news and features. Radio editor, Saul Emanuel.

A Warning to WHN!

RADIO WORLD has received complaints from a number of fans regarding the "rough stuff" broadcast from Station WHN, Loew's State Theatre, New York City. Mixed with a hodge podge of vaudeville and variety songs and music are remarks from the announcer and some performers that closely approach the offensively vulgar.

WHN is reminded that almost every sound in the studio is transmitted and the audience reached always includes refined people of both sexes. Here is a case where responsibility and obligation should go hand in hand with privilege.

Radio Literature Wanted

Manufacturers of and dealers in radio apparatus and accessories are notified that literature and catalogues describing their products have been requested, through the Service Editor of RADIO WORLD, by the following:

R. M. Seward, 107 Logan St., Altoona, Pa.

Frank La Valle, 2529 Cambrelleng Ave., New York City. (Wants to establish retail radio business on small scale.)

J. P. Fitters, 224 Adam St., Steubenville, Ohio.

Clarence Gibbons, 342 Exchange St., New Haven, Conn.

J. E. Greene, 64 Sheffield Ave., New Haven, Conn.

C. B. Gowan and R. L. Lockett, 515 Galveston Ave., Fort Worth, Texas. (Retailers. In market for parts.)

Michael E. Kondrat, 94 Exchange St., New Haven, Conn.

Einar Aarnodt, Room 310, Hort Bldg., University Farm, St. Paul, Minn.

C. F. Colton, 26 Ningkno Road, Shanghai, China.

Robt. B. Clark, 1247 Texas Ave., Sawtelle, California.

A. C. Pforzheimer, Broadway, Woodmere, N. Y. (Wants agencies for reliable manufacturers.)

Paul Nilsen, Box 1010, South State St., Jackson, Miss.

Joseph M. Edwards, P. O. Box 207, Tukegee, Alabama.

Roy Ruskin, 314 Morgan St., Boonville, Mo. (Retailer. Wants wholesale prices.)

Merle Abrams, Box 894, Burkburnett, Texas.

Harry A. Muir, 532 Cherokee St., Denver, Colorado.

L. W. Macomber, 377 Somerset Ave., Taunton, Mass.

George C. Blackwood, 243 East Upsal St., Mt. Airy, Philadelphia, Pa. (Wants hinged lid cabinets, 12x14 or 12x18, or sizes between these.)

Chas. Whiting, 7120 Fifteenth Ave., Brooklyn, N. Y.

The Radio Sales & Service Co., 609 Freeman St., Lyndhurst, N. J.

Wesley Blalock, P. O. Box 315, Montgomery, Ala.

Alfred T. Maund, Jennings, La. (Dealer.)

L. J. Hamilton, 909½ Steiner St., San Francisco, Cal.

G. D. Wilcoxon, 1414 Seventh St., Santa Monica, California.

C. W. Ferguson, 15 Wyoming St., Roxbury, Mass. (In market for a three or four tube set.)

Byron Miller, Star, Oregon. (In market for parts of a good commercial set and a 50 watt transmitting outfit.)

Lake County Overland Co., Leesburg, Florida. (Installing radio department.)

Jack A. Segel, 800 Dorian Court, Far Rockaway, N. Y. (Wants to purchase receiving set.)

Richard Burch, 30 Fifth Ave., New Rochelle, N. Y. (Wants receiving set and loud speaker.)

E. C. Giggy, Orosi, California.

L. L. Price, 514 Chestnut Ave., Du Bois, Pa.

C. G. Richardson, 2012 Avenue G, Brooklyn, N. Y. (Interested in fixed mineral detectors for reflex circuits.)

Louis Nathan, 72 Rodney St., Brooklyn, N. Y.

J. A. Shields, 688 Howard Ave., Bridgeport, Conn.

J. G. Kaufman, 117 Avenue C, New York City.

New Brandes Factory

C. BRANDES, Inc., 237 Lafayette St., New York City, manufacturers of the popular "Matched Tone" headsets, have purchased a new factory at Newark, N. J., containing over 46,000 square feet of floor space. With its other factories the company will now utilize over 70,000 feet of floor space all devoted to the manufacture of headsets.

Broadcasters Urge Change in Copyright Law

IN a friendly suit brought by M. Witmark & Sons, well-known music publishers of New York City, against L. Bamberger & Company, department store proprietors and owners and operators of broadcasting station WOR, Newark, N. J., in the United States District Court for the District of New Jersey, to determine whether the broadcasting of copyrighted music by radio violated the copyright law, Judge Lynch decided that it did, and ordered:

"A decree will be entered in favor of the plaintiff, but restrain will be withheld pending a review of this opinion."

Judge Lynch concluded a lengthy opinion as follows:

"There is another point which, although striking us as immaterial, deserves some comment. The defendant argues that the plaintiff should not complain of the broadcasting of its song because of the great advertising service thereby accorded the copyrighted number. Our own opinion of the possibilities of advertising of radio leads us to the belief that the broadcasting of a newly copyrighted musical composition would greatly enhance the sales of the printed sheet. But the copyright owners and the music publishers themselves are perhaps the best judges of the method of popularizing musical selections. There may be various methods of bringing them to the attention of music lovers. It may be that one type of song is treated differently than a song of another type. But, be that as it may, the method, we think, is the privilege of the owner—he has the exclusive right to publish and vend, as well as to perform.

"Considering all of the facts and circumstances, it is the conclusion of the Court that the broadcasting of the defendant was publicly for profit within the meaning of the Copyright Act as that meaning has been construed by the United States Supreme Court."

The National Association of Broadcasters, 1265 Broadway, New York City, through Paul B. Klugh, executive chairman, has issued a statement in connection with the decision, as follows:

"This decision justifies the position taken by this association from its inception:

"1. That our efforts be directed toward a revision of the Copyright Act, rather than any contest in the courts under the present ambiguous law.

"2. That, because of the proven value of broadcasting in creating sales of sheet music, phonograph records, and piano player rolls (now admitted by Judge Lynch in his decision) it is unreasonable for any musical copyright owner to demand payment for use.

"3. That the American Society of Composers, Authors and Publishers controls but a small percentage of the copyrights recorded in Washington and therefore are in no position to make any concerted demand.

"4. That our Bureau of Music Release furnishes weekly (for use by members only) good, new, copyrighted, popular music without the payment of any fee or tax.

"With our rapidly growing membership and the strength which comes from numbers, the future of the broadcasting art becomes clearer."

RADIO WORLD, in its issue of April 21, 1923, pointed out a way by which the broadcasters could beat the music publishers. This advice seems worth repeating at this time. In brief, it was as follows:

"Let us assume for a moment that we are running a broadcasting station. We receive nothing directly from this service. We do not want to be penalized for broadcasting songs and instrumental pieces which not so long ago the music publishers were dying to have everybody use, and in some cases paid handsome weekly or lump sums to vaudeville singers and other musicians for using. As broadcasters we know we are offering a great public service to radio and the public at large, and feel that the fees demanded should not be paid.

"Supposing, however, that a fair argument does not bring the publishers to terms, what then can be done? The answer is simple. Every music publisher is obliged to boost his numbers so that singers will put them in their repertoire, phonograph companies will record them, and eventually the public will buy them.

"Broadcasters can adopt practically the same method. Good song writers—and some of the most popular and successful in the business—can be engaged on a salary or royalty basis and if their output is released through all the other broadcasting stations there would soon be such a demand for these numbers that the music dealers throughout the country would be placing their orders for hundreds of thousands, and, in some cases, millions of copies. These new numbers could also be released through singers, orchestras, etc., and practically the same method of boosting procedure adopted as is now used by the biggest music publishers.

"Broadcasters should not worry at all when it comes to a matter of getting up-to-date material. They can make their own. They can popularize it in a more expeditious and thorough way than was ever known in the old days of 'song-plugging.' All they have to do is to adopt the methods of their friendly enemy and go right into the song and instrumental sheet music business themselves in the manner indicated."

False Rumor Mongers Being Sought

AN investigation to determine which of the nineteen commercial broadcasting stations, or 2,600 amateur stations, within the second radio district, started the false report previous to the actual event, that President Harding was dead, and that Mrs. Harding had died from the shock has been started by Arthur Batcheller, United States Supervisor of Radio, who has offices in the Custom House, New York City. If the originator of this fraud is discovered his prosecution will be asked, under a Federal radio communication law.

Bolton Hall Tells How to Bring Good Times

WHAT a joke it is to prove that if no one bought anything but hash and corduroy, we would all be rich—at least if we handed our money over to the bank, writes Bolton Hall in Forbes Magazine. But what the bank would do with the money if no one spent anything does not appear.

Simply cutting down our expenditures is simple enough—almost idiotic. It is simply cutting down business, making a "buyer's strike," which is the most stupid of all strikes. To avoid hard times we must keep our expenditures up, increase them if possible; but see that they are made not wastefully but productively.

Don't try to "save" paint on your house or wear shoes with the heels worn down. These are wastes that make want.

We laugh at the old lady who took the remainder of the emetic after she was well "to save it," but we sometimes eat food when we are not hungry "to save it." Better give it to the poor and save your ice, or to the chickens and save your digestion.

True Thrift is the philosophy of saving by spending, particularly by buying productive things, including securities. "Life is not made for savings; savings are made that life may be more abundant here and now."

Can't Sell American Radio Goods in England

THE restrictions against the use of any radio equipment except that licensed by the British Broadcasting Company are making it impossible for English merchants to sell American radio products, according to a report just submitted to Washington by United States Consul Ross E Holaday, from Manchester, England.

Consul Holaday, making an investigation of the radio situation, found that the restrictions upon the use of equipment and the regulations governing the use of wireless sets give the British Postmaster General, through his arrangement with the British Broadcasting Company, an ironclad control over radio. There is no prohibition against the importation of foreign radio products, or against their sale after importation, but this freedom is nullified by the difficulty of securing a license to use any equipment other than that endorsed by the "B. B. C." which collects a royalty on every set manufactured in England.

There is now under consideration by the British authorities the issuance of a new form of license to be known as the "constructor's license," under which people with no technical knowledge will be permitted to assemble wireless sets and use them to receive broadcast and other matter. Even those who purchase the sets manufactured under B. B. C. restrictions are required to secure a license before they can make use of their outfits. This is known as a "broadcasting license" and costs approximately $2.50. Only those persons having "experimental licenses" are permitted to assemble their own apparatus, and to secure such a license the applicant must have a knowledge of the technical side of radio which the majority of would-be listeners do not possess.

Marvel Capacity Switch

Three-Ways Series, Parallel, Direct-ground

Patents pending

DIAL MOUNTED

Efficient reception is the ability to switch from the short wave lengths to the long, or from the long to the short.

The Marvel three-way switch receives short waves in the series position; long waves in the parallel position, and waves of medium length in the direct-ground by eliminating the condenser entirely.

Strictly of anti-capacity type.

Price....$1.25

Attractive discounts for dealers and jobbers.

The Wireless Oracle Speaks

By Billy Bronx

WGR seems to get through regularly these days in spite of all the static. Their programs sure are the berries.

Had some 95% vocal talent from WIAD, the Ocean City Golf Club, of Ocean City, N. J.

Say, WEAF, where do you get all those good orchestras? This time it's the Bruno Brothers' Orchestra. They sure are some jazz babies. What do you say?

We sure did miss you last Sunday evening, Roxy. Let's hope that this unforeseen occasion will not arise again.

William Bruno, you may be another Lopez at the piano, but you're far from another Gilbert or a Charley Tobias with your voice.

Too bad you're not on the air more often, WJAX. Your popular programs sure do make a hit with me.

Have you noticed how busy Lillian May Challenger, the soprano, is these days? She is another one of our prominent artists who always seems to be thinking of the listener-in. Isn't that your impression also?

WMAF is another station that gets through regularly these days. Your programs are a delight, but your modulation is still too full.

By the way, WMAF, is your slogan "The Land of the Pilgrim Fathers" or "Away Down East"? At present you've got me guessin'.

The Melody Belles are some Toodlety-Oot-Tum-Tums and plenty of it. If you didn't hear them you sure did miss something.

You may think that Loew's, Keith's, Fox's or Proctor's offer you the best in vaudeville, but if you tuned in WHAZ last Monday night you would have heard something that has them all beat. To those who listened in: Do you agree with me?

More competition for you, Roxy. First it was the Strand Theatre and now it's Marcus Loew and his crowd. You'd better keep a steppin' lively!

We fight fans sure did enjoy your short talk, Jimmy De Forest. Some of you other limelights of the fighting game ought to make it your business to keep it a-goin'.

Phil Ohman and his Trio sure did make a hit with us. Too bad they were not booked for the evening hours.

Now that we've heard "Adrienne" over the air, we're going to see it. Are you with us?

No doubt you have heard or have seen pictures of amateur stations that are claimed to be as good as broadcasting stations, if not better. Well, to be convinced that this may be true, I would suggest you listen some evening to 2RB who uses phone a great deal and is on a wave length of about 190 meters.

Have you noticed the way the stations in the East, or New England States especially, come through these days? Seems as if the weather agrees with them.

You may have heard two stations broadcasting the same program at the same time, but did you ever hear three stations broadcasting the same program at the same time? If you want to try this, then tune in WEAF on 492 meters, WCAP on 469 and WMAF on 360.

Do You Want LONG DISTANCE on Your Set?

The following stations have been heard with a COAST COUPLER

WDAP—Chicago
CFCN—Calgary
WWJ—Detroit
PWS—Havana
WSB—Atlanta

And Many More

The COAST COUPLER is a necessary part of your radio hook up. Manufactured of the best materials obtainable and thoroughly tested before leaving the factory, it has immediately won recognition in the radio market.

No Age Limit in Radio Broadcasting

THE all-embracing auditorium of the air knows no limitations as to age. The great radio audience asks only that the artists entertaining it shall be capable, pleasing and entertaining. Radiophone Station WHAZ, at the Rensselaer Polytechnic Institute, Troy, N. Y., having presented in its weekly concert program of July 30 the oldest singer ever heard through the broadcasting medium, Calvin Dater, of Troy, an eighty-five-year-old baritone, who was greeted with a "storm of applause" in the form of messages of appreciation, swung to the other age extreme the next Monday evening, and offered in its concert program solo numbers by Beatrice Gilbert, a nine-year-old pianist of unusual skill for her age, and duet numbers with her brother, Eugene Gilbert, a thirteen-year-old violinist.

"Listening In"

How Do Crystal Sets Get Distance?

EDITOR RADIO WORLD: Much has been said and written in technical books pro and con regarding the fact that re-radiation of receivers and the oscillations from nearby transmitters are the cause of distance reception on crystal sets.

I am the owner of a receiver of the crystal type, using a tuner, crystal detector, variable condenser and phones, and have done some fine work up to 100 miles.

The other evening while listening in, I tuned down to 200 meters to enjoy a little of the spark work of some of my neighboring amateurs, but soon growing tired, tuned back to phone wave lengths. My neighbor on the next block has an amateur 20-watt phone transmitter and he started in to talk to a friend of his. While he was on (about two minutes), I distinctly heard station WGY, Schenectady, and the moment he signed off, WGY faded right out and things went along on the usual plane.

Located as I am hundreds of miles from that station, I think that this proves that most of the long distance work of some of these crystal fans is due to enforced oscillation from nearby CW and phone transmitters and multi-tube sets rather than to superfine crystals.

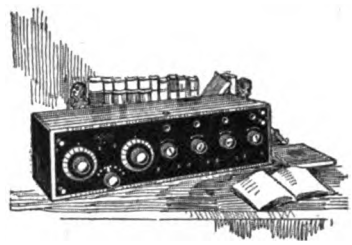
If it doesn't prove it in anybody's mind, I would like to have them explain the phenomenon to me in a manner that will convince me. I am open to argument.

Yours for an early argument on the matter,

PHILIP KEANSBY

Wilmington, North Carolina.

Note: This should hit somebody's pet theories on re-radiation and crystal sets hard.—Editor.



TUNE IN THE WORLD WITH A CROSLEY MODEL X

No matter where you live, the news and pleasures of the world are an open book to you if you own a Crosley Model X.

A man from Belleville, Kansas, writes: "I have found the Crosley Model X to be the best radio receiving set I have used, and permit me to say that I have been interested and using radio sets since the spring of 1922, including all standard makes."

In spite of new features such as the R. F. T. A. Coil and the Multistat, the Crosley Model is still priced at $55.00.

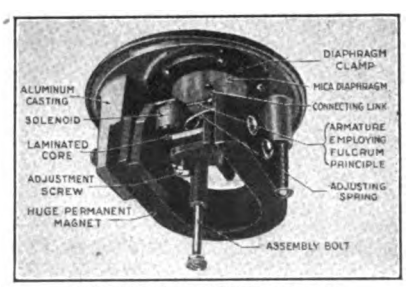
21" FIBER HORN
$25.00

TYPE "B"
(For Phonographs)
$12.50



INTERIOR CONSTRUCTION

An ear phone is an ear phone no matter how fancy the horn that covers it may be, and, due to the delicate construction of an ear phone it is utterly incapable of giving true tone reproduction, especially, when relatively large currents are passed thru its coils, such as the output of a two-stage or power amplifier.

The Trinity Loud Speaker element embodies the well-proven and tested principles of the phonograph reproducer with the soundest principles of electromagnetic design best adapted for loud speaker operation. It is not an ear phone when placed on a head band and a loud speaker when covered with a horn. It is a sturdy loud-speaking element ALWAYS.

Program for the Amateur Convention at Chicago

EVENTS of absorbing interest to all radio men are to be crowded into five days of concentrated activity, including technical talks fertile with most recent developments in the radio world, when the largest gathering of amateurs in history convenes in Chicago September 12-15 for the Second National American Radio Relay League Convention, under the auspices of the Chicago Radio Traffic Association, according to the elaborate program just prepared.

Never has there been such a widespread turnout of amateurs as that expected to roll into Chicago from all sections of the United States and Canada, opening the fall radio season with a spectacle excelling all previous conventions and "hamfests." Officers of the A. R. R. L. and other speakers of national prominence call for a full attendance at technical meetings for DX men during a discussion of international amateur tests and achievements.

One of the most timely subjects to all amateurs who have participated in recent transoceanics is the proposed two-way communication tests over the Atlantic and the Pacific. Every conceivable kind of oceanic amateur traffic, from transmissions of signals to complete messages, has been successful, but never have two amateurs established direct contact.

This question and tentative plans for the two-way tests will be taken up at a meeting Thusday afternoon of the A. R. R. L. Traffic Department under chairmanship of F. H. Schnell. Other semi-technical meetings will be held during the convention.

An elaborate banquet at the Edgewater Beach Hotel will precede, rather than wind-up the events as the custom has been in the past, the object being to provide at the outset an opportunity for delegates from all sections to become acquainted.

Some of the time will be given over to field events and various games and contests will be staged between groups of amateurs representing the various A. R. R. L. operating department divisions.

One of the stunts designed to furnish a great deal of amusement will be the search for a hidden transmitting station by means of portable loop receiving sets. This scheme will carry visitors here and there throughout the city on foot, or in automobiles, looking for the mysterious operator, whose position will be carefully chosen.

A special effort is being made by R. H. G. Mathews, central division manager of the League, and other committee men to provide a program which will be of interest to the broadcast listener as well as the amateur and talks covering all phases of broadcast transmission and reception are scheduled for the convention.

A "Night of mystery" is the term selected for the last evening when visitors will be invited to witness the initiation of candidates into the "Royal Order of the Wouff-Hongs." A wierdly elaborate ritual has been prepared and the initiation itself is to be in charge of a group of amateurs from Flint, Mich., at which city the amateur secret order originated.

The weapon known as the "wouff-hong" is an instrument of torture designed by the "Old Man," for years an anonymous contributor to the League's official organ, "QST."

Coming Events

AMERICAN RADIO EXPOSITION, Grand Central Palace, New York City, October 6 to 13, 1923. J. C. Johnson, general manager.

ANNUAL HOME AND CITY BEAUTIFUL EXPOSITION, featuring radio exhibits, Atlantic City, N. J., June 16 to September 8, 1923.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS, Pacific Coast convention, Del Monte, Cal., Oct. 2-5. F. L. Hutchinson, 33 West 39th St., New York.

AMERICAN RADIO RELAY LEAGUE, second national convention, Chicago, Ill., September 12-15, 1923. Chicago Radio Traffic Association, 959 The Rookery, Chicago, Ill.

Seek Relaxation of German Restrictions

EFFORTS to secure a relaxation of government restrictions under which private radio installations are prohibited in Germany are being made by a radio club established in Berlin early this year, according to a report from Consul E. Verne Richardson to the Department of Commerce.

It is commented that Germany lags far behind many other countries in private radio enterprise, a great contrast to pre-war times, when Germany was well in front in radio matters.

At a recent meeting of the Berlin club there was demonstrated a loop antenna by means of which London could easily be heard.

A B C of Aviation

By CAPT. V. W. PAGE. This book describes the basic principles of aviation, tells how a balloon or dirigible is made and why it floats in the air. Describes how an airplane flies. It shows in detail the different parts of an airplane, what they are and what they do. Describes all types of airplanes and how they differ in construction; as well as detailing the advantages and disadvantages of different types of aircraft. It includes a complete dictionary of aviation terms and clear drawings of leading airplanes. The reader will find simple instructions for unpacking, setting up and rigging airplanes. A full description of airplane control principles is given and methods of flying are discussed at length.

This book answers every question one can ask about modern aircraft, their construction and operation. 275 pages, 130 specially made illustrations with 7 plates. Price, $2.50

A Good Tip for DX Nite Owls

EDITOR, RADIO WORLD:—I have in the course of my reading RADIO WORLD since it started always had a sneaky idea that I would like to write a letter to the editor, but have never had a chance to get anything to talk about, as everything always seemed to be answered before I could ask it. However, I have at last found an outlet for my wish.

I note that you have had article after article, small and large, concerning the importance of grid leaks being variable, yet never have I seen an article concerning the grid condenser being variable. Personally I have found out that it is equally as important for the grid condenser to be variable as for the rheostat to be variable. I have tried out numerous single circuit sets by White, Gordon, Thompson, Dougherty, and others of your writers. I am not the kind of an amateur that is satisfied with a set, but get most of my fun out of life by making and trying them all. I scarcely keep a circuit more than a week, if that long. I sometimes construct three and four at a time by means of a board with clips, and compare the working of them on a single DX station under the same conditions.

Instead of using the conventional fixed condenser, I use a small three plate variable, connected in parallel with three fixed condensers, so that I can obtain any value from .00001 (pretty small, but I have it) up to .005, and find that a variable condenser of this sort is just as necessary to tuning in DX with volume as any grid leak ever made. I use two .002 fixed condensers in parallel with a .001 fixed and a three plate variable.

I have noticed when using the new UV199 tubes in connection with radio-frequency that this arrangement improves my detector over 100 per cent, and therefore I am giving the idea to the fans through my favorite periodical, RADIO WORLD, hoping that it may help some of the other readers solve some of their DX problems this fall and winter, when they try out some of the new circuits that you publish.

Yours for a DXing year,

JOSEPH BENDA.

Palo Alto, California.

Information from WKAQ About Porto Rico

PORTO RICO—What and Where It Is" is the title of an interesting booklet sent out by the Radio Corporation of Porto Rico, San Juan, Porto Rico. This statement is made:

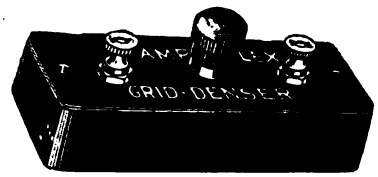
"In the radio logs of thousands of listeners in the Western Hemisphere, two broadcasters occupy honored positions. These stations are WKAQ of the Radio Corporation of Porto Rico, and PWX of the Cuban Telephone Company, Havana, Cuba, both affiliated with the International Telephone and Telegraph Corporation of New York.

"That they are of invaluable service in building a better knowledge of these two lovely islands is proven by thousands of letters received, and which come from Alaska, Canada, the United States, Mexico, and our sister Republics of Central and South America.

"WKAQ hopes that you will enjoy this pamphlet and will tell you more about Porto Rico by radio."

AMPLEX GRID-DENSER

A Variable Condenser (.0005) for the Grid Circuit.



"Delighted with results." — **Scientific American.**

"Use in our Laboratory."—**Prof. L. A. Hazeltine.**

"Works like a charm."—**Dallas Times Herald.**

"Have an excellent set, but failed to get long distance. Placed 'Grid-Denser' in and have picked up 1,000 miles."—**Chas. F. Smisor, Editor, Radio Digest.**

Approved and recommended by Radio Laboratories of Radio News, Radio World, New York Mail and other experts.

DOUBLES the efficiency of your set.

Greater distance
Sharper tuning.
Louder and clearer signals.

PRICE $1.25

RADIO WORLD'S
FALL BUYERS' NUMBER

DATE OF IMPORTANT ISSUE—OCTOBER 3
(LAST BLACK FORM CLOSES SEPTEMBER 27)

Hundreds of thousands of radio enthusiasts who will be returning from their vacations, to say nothing of the army of new radio fans that will come into the radio fall season for the first time, will look forward to the buying of sets and general radio equipment in the autumn. Radio World will devote a special issue to these potential purchasers of goods—the **FALL BUYERS' NUMBER.**

Our regular advertising rates will be in force as follows: $5.00 per inch, single column $50, $150 per page, with discounts of 10% four times, 15% thirteen times, 20% fifty-two times (yearly) contract. Classified, 5c a word.

Special service and value to advertisers in Radio World's **FALL BUYERS' NUMBER.** All advertisers who give us copy for quarter page or more space in Radio World's **FALL BUYERS' NUMBER** will, on request, have their announcements appear in **two colors at the price of one**—in case copy is in our hands by September 22.

Radio World is already at work on a country-wide circulation campaign for **FALL BUYERS' NUMBER,** which will be so interesting from a pictorial and text standpoint that it will have an unusually large sale and advertisers will receive unusually fine value.

IMPORTANT NOTICE
While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

A Sharp Stick Is Better Than Radio Commands for Elephants

YES, we don't care much for wireless," was the verdict of Indarini, one of the elephants of the Regent's Park Zoo, says a London cable to the New York Tribune, when an experiment was made to see whether the animal would obey the keepers' voice, coming from a loud transmitter of a wireless telephone set.

Pondering on the spread of the broadcasting craze, some zoo officials wondered whether it would not be possible for the keepers to give orders to their charges over the wireless. They arranged a demonstration, with Indarini as a subject.

At 6 o'clock Syed Ali, the Indian mahout who rules over the zoo elephants, began issuing orders in Hindustani over the radio. His first command was, "Lie down!" Indarini glanced contemptuously at the horn just outside her cage and went right on eating her potatoes.

The second command, ordering her to "Stand up," seemed merely foolish to her, as she had not obeyed the first order. While other instructions were being issued from the set she simply finished her dinner and looked disgustedly at the horn.

Then the keeper, who was present, advanced and gave the same orders. Incidentally, he emphasized them by jabs with a sharp stick. Indarini obeyed immediately, but did not even glance up when the good-night signal came over the wireless. Zoo officials have decided for the time being to stick to the old-fashioned methods.

Construction of New Type Transatlantic Receiving Sets
By M. B. SLEEPER
Fully Illustrated. Price 75 Cents
IN addition to the listening to ships and broadcasting stations on short wave lengths there is a peculiar fascination about listening to the high-power telegraph stations of England, France, Germany, Russia and Italy as well as those located in the Pacific Ocean and the Oriental Countries. It is much easier to do this than most people imagine. The sending is very slow, a feature of assistance to the beginner in telegraphy. Several types of receiving sets for this task are described. Detectors, amplifiers, oscillators, etc., for long distance reception are also described. Suggestions for the operation of relays by the signals and the reproduction of them on a phonograph are given. In addition there is some valuable data on home made wavemeters for testing and experimenting.

This Offer Good Only Until September 15, 1923

Why Rita Cries

(C. Fotograms, N. Y.)

Here is a poser for you, radio fans. You should be able to tell at a glance just why Rita Kaplan, the amateur radio fan, is crying her eyes out. It is simple, and yet it is enough to make her "shed tears salty, and cry loud and long." Well, have you found it out yet? No? Just take a peek at the upper right hand corner of the receiver and you will see that one of the phone cords has come loose and the program stopped just as "——the big brown bear jump———" and incidently spoiled the entire evening for Rita, who never, never, never can sleep unless she hears her "bed-time story."

Antennaless Radio

DR. LE ROY SATTERLEE, the famed X-ray expert and radio inventor, delivered his first radio lecture from Station WOR (L. Bamberger & Co.), Newark, N. J., last Saturday night. His subject was "The Possibilities of Antennaless Radio."

Dr. Satterlee has devoted twenty-five years of his life to the development of the X-ray and he is directly responsible for many important discoveries. He is one of the half dozen survivors of the pioneers in Roentgen ray work. He owned the second Crookes tube in America and had much to do with the development work which led to the perfection of the lead glass screen now used to safeguard X-ray operators. He is also credited with making the first dental X-ray photograph and was laughed at by dental experts and physicians in dental work, though the same system is now used universally in modern dentistry.

The scientist-inventor is indeed a real martyr to his work. He has given the best years of his life, at the cost of both wealth and health, to science and humanity. At the present time he is practically an invalid. Some months ago when he was forced to abandon X-ray experiments because of terrible X-ray burns, which caused the amputation of half of his left hand and also seriously affected his heart action, he took up radio. Since then he has perfected a new type of receiver.

Among other things, the Doctor maintained that radio waves and light waves are much alike, though the latter are of a much higher frequency and shorter wave length, and claims that electromagnetic waves may be reflected and refracted by properly arranged units just as light waves may be controlled by mirrors, prisms and lenses. In the last instance his argument is very well borne out by the work being done by C. S. Franklin, in England, which Marconi himself dwelt upon so forcibly in his lecture before a joint meeting of the Institutes of Radio and Electrical Engineers on his last visit to the United States.

Franklin's work, however, deals with a system for directing the waves sent from a transmitter while Dr. Satterlee has devised a method for directing the waves within a receiver in order that they may be properly focussed upon the unit used in the secondary circuit.

A few weeks ago a series of experiments were made on board moving trains in Canada by the aid of Dr. Satterlee's receiver, with astounding success.

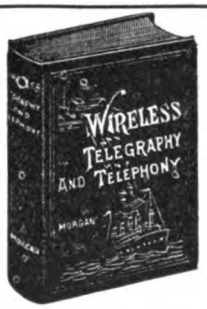
Radio Books for Your Vacation

Telling How to Operate a Radio Set—How to Build a Set—Principles of Vacuum Tubes and Other Radio Problems



Wireless Telegraphy and Telephony Simply Explained

By ALFRED P. MORGAN

One of the most complete and comprehensive treatises on the subject ever published. A study of its pages will enable one to master all the details of the wireless transmission of messages. The author explains in simple language the theory and practice of wireless telegraphy and telephony. 154 pages, 156 engravings.....PRICE $1.50

The A B C of Vacuum Tubes Used in Radio Reception

By E. H. LEWIS

Assoc. I. R. E., and Radio Instructor

Written particularly for the person who "knows nothing about radio," but who would like to gain an understanding of the elementary principles of operation of vacuum tubes and various circuits in which they are used for the reception of radio-telegraph signals and radio-telephone music and speech. Illustrated.....PRICE $1.00

Experimental Wireless Stations

By P. E. EDELMAN

Tells how to make apparatus to not only hear all telephoned and telegraphed radio messages, but also how to make simple equipment that works for transmission over reasonable long distances. Then there is a host of new information included. The first and only book to give you all the recent important radio improvements, some of which have never before been published. 392 pages, 167 illustrations.....PRICE $3.00

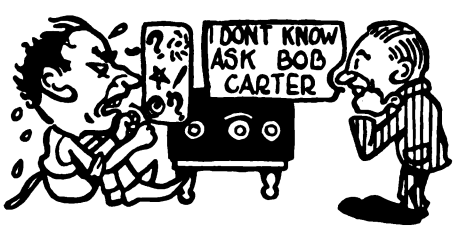
"It's easy—when you know how"

The amazing story of Bob Carter, a radio amateur, who became an authority overnight and surprised his friends

By Frank W. Daly

WHAT in blazes was the matter with the darned thing anyway? I was mad clean through. I'd been fiddling with my new set for hours and all I was getting was a weak little chorus of six stations and a lot of howls and squawks. Harry Brant was there offering his usual line of stupid suggestions which only made me angrier. "Don't stand there looking at me!" I bawled. "Why don't you **do** something? Why don't you tell me what's **wrong** with the thing?"

Harry shrugged his shoulders helplessly. "Sorry, old man, I don't know enough about Radio—you'd better ask Bob Carter, he's the authority around here these days."



"**Bob Carter!**" I shouted in derision. "What are you trying to do—kid me? Since when has Bob Carter become a rival of Major Armstrong? Bob Carter! That's a hot one. Say—three weeks ago that boob asked me if a microfarad was a disease germ."

"Just the same, Bob is an expert!" said Harry, defiantly.

"Huh!"—you've **got** to show me," I sneered. "Why don't you phone that nine-day-wonder to come over here and see what he can do with **this** set?"

"All right, I will," said Harry.

Fortunately, my sense of humor came to the rescue just then and I was able to laugh at the picture of utter helplessness I would soon be enjoying when poor Bob Carter started "fixing" **this** receiver.

Bob answered Harry's call and said he'd be right over. "—Always glad to be of service." Stupid egotist!

"What's the trouble?" asked Bob, on his arrival a few minutes later.

"Nothing much," I replied non-committally—I didn't want him to have any clues.

"Dandy set!" he commented, surveying my outfit —and I had to admit he sure handled the thing like a seasoned amateur. "There's **nothing** wrong with it," he said, after a moment, "except—"

With the ease and confidence of an experienced engineer he made some minor adjustment inside the cabinet.

"—Except **this**!"

To my astonishment WEAF suddenly burst out with a knife edge clearness and freedom from interference.

"Why Bob—" I gasped. I couldn't conceal my admiration. "Gee! You're **great**! Where did you—? How—? Say—am I crazy or something?"

Bob chuckled—he knew what I was thinking. "Pshaw! There's nothing to it." He protested, modestly. "Either of you fellows could do it in half the time it took me. Just think—I can make the **dandiest** receivers now, and trouble-shooting? Easy as falling off a log! But really—there's no credit due me **at all**. It's **easy** when you learn Radio the way I did."

I was quite prepared to believe the moon was made of hard-rubber by this time. "Of course, we aren't a **bit** anxious to know how you did it!" I said ironically.

"There's nothing much to tell," said Bob. "You remember I didn't know a **thing** about Radio, but I was anxious to learn. Still, I didn't feel like wading through miles of mathematics and verbosity to reach my goal. One day—reading a radio magazine—I happened to glance at the advertisement of the Radio Guild and saw that Kenneth Harkness had written a **new** kind of home-study book on **advanced** Radio, a book that assumed you hadn't the **slightest** knowledge of Radio, yet which dealt with the most advanced phases of the subject. This was exactly what I had been waiting for. I mailed the coupon and they shot me the book by return mail.

"Well, sir! That very first night I felt myself growing in knowledge—it was wonderful! There was no exhausting fight for understanding because everything was delightfully clear. Each subject

was taken up so smoothly I clean forgot I was studying something that had been considered ponderously scientific. Why—within the first **week** I was building my own receiver, and you ought to see it! Huh! It looks **better** than most **commercial** receivers and—well, that's all!"

I couldn't get the Radio Guild's address from Bob quick enough. I even used a special delivery stamp on my letter to the Guild. They rushed me my copy of this astounding book by return mail and eagerly I commenced reading. It was called "Radio Frequency Amplification," and if I was surprised at the knowledge Bob Carter had gained, I was even more dumbfounded at my own success. I tell you there wasn't a **question** on Radio I couldn't answer instantly and with perfect confidence. I was **absolutely sure of myself.** And as for building sets—well, I've just taken another order for a six-tube receiver. I shall make over a hundred dollars out of it. Is **that** reason enough for enthusiasm?

Now the above is a **true** story. Just think—Bob Carter was below average—yet, he became a real authority. If **he** could achieve such wonderful results in such a surprisingly short time, and with such ease—think what **YOU** could do! Yes—**you** can do better than Bob Carter. It doesn't make a jot of difference whether you've been a radio bug for years or whether you're an absolute beginner. In his new book, "Radio Frequency Amplification," Kenneth Harkness will lead you step by step from the elementary principles to the most advanced aspects of modern radio reception. Just a few minutes a day with this book and **you** will be the authority among your friends. There won't be a thing that'll stump you—not a question you can't answer.

With the aid of this book you will know how to construct the most up-to-date receivers—superior to any of the commercial sets made today. The assembly and wiring of several different types are explained thoroughly and illustrated by scores and scores of diagrams, drawings and action photographs. Could anything be simpler? Yet remember—you will be taught the most advanced and modern developments, **you will be told professional engineering secrets of manufacture never before revealed to the amateur radio constructor.**

SPECIAL LOW-PRICE QUICK ACTION OFFER

"Radio Frequency Amplification" with its handsome red binding, its eight meaty lessons on theory and seven closely knit lessons on intensive practice has met with an instantaneous, smashing demand! So we cannot urge you too strongly to send for your copy **today** before the edition runs out. To induce quick action on your **part**, the senders of **the** first five hundred coupons will receive this wonderful new book **AND** "Super-Regenerative Receivers" by the same author—both books for the astonishingly low price of only $1.25!

SEND NO MONEY

Simply fill in and mail the coupon below—when the books arrive pay the postman only **$1.25** plus a few cents **postage.**

THE RADIO GUILD, Inc.
256 West 34th Street, New York, N. Y.

Please rush me my copy of the new book, "Radio Frequency Amplification," by Kenneth Harkness. I understand you will send me "Super-Regenerative Receivers" by the same author as a special inducement. When the postman arrives I will pay him only $1.25 plus a few cents postage. (Outside U. S., $1.50 cash with order.)

A UV199 OUTFIT COMPLETE FOR $20 (See Inside)

15c. a Copy September 1 $6.00 a Year

RADIO WORLD

Title Reg. U. S. Pat Off.

ILLUSTRATED EVERY WEEK

SOME ORIGINAL AMERICANS ENJOY A BROADCAST PROGRAM

(C. Kadel and Herbert)

Twenty-seven Arapahoe Indian braves and squaws, not to mention papooses, who arrived in New York from the Wind River Reservation, Wyoming, en route to England, were entertained by a loop receiver. They gathered around it like they used to gather around the old camp fires and listened to the programs, making comment much the same as any radio wise man and woman of today will do. Those in the illustration are Mr. and Mrs. Red Turtle, Setting Eagle, White Bull and Red Fox. They enjoyed the concerts and solos much more than the talks on politics and current topics.

Station WHAZ to Celebrate Its First Anniversary

RADIOPHONE STATION WHAZ at the Rensselaer Polytechnic Institute, Troy, N. Y., the oldest engineering college in America, will celebrate its first anniversary Monday evening, September 10, with a program by the same group which presented the first program when this station was opened a year ago. Dr. Palmer C. Ricketts, President of the Institute, will deliver a brief address.

Station WHAZ has already performed many unique feats. Installed through a gift of $30,000 by the Roeblings, graduates of the Institute, famous as the builders of the Brooklyn Bridge, this station was primarily intended for use in connection with the electrical engineering course at the Rensselaer Polytechnic Institute and for wireless experimental purposes, which are regularly carried out with many interesting scientific developments. It was decided to devote it one evening each week (Mondays only) to the entertainment of the radio audience, and during the cooler season its programs, which run the whole gamut of entertainment and instruction, are heard regularly from coast to coast, from Alaska to Panama, in Hawaii, Cuba and at sea.

WHAZ was one of the first stations in America heard in continental Europe last November. It was the first eastern station heard in Hawaii last December. This station established the long distance record of the world in February, when test early morning programs were picked up on four days at Invercargill, New Zealand, a distance of 10,000 miles from Troy, further than the human voice had ever been carried before without wires. It accomplished the first transcontinental two-way radiophone transmissions in January and February with station CFCN at Calgary, Alberta, Canada, with programs and messages interchanged simultaneously. A new summer distance record was made in June when a midnight concert by Doring's Band and soprano solos by Mrs. William T. Lawrence were clearly heard in complete form at Hollywood, California. Even during the periods of greatest static interference reports show that its programs are heard with remarkable clearness as far west as the Rockies, south to the Carolinas and throughout the Eastern Canadian Provinces.

In physical equipment station WHAZ is very similar to several other large stations throughout the country, operating a 500-watt Western Electric broadcasting equipment, though its location on top of the big Sage Laboratory on the crest of the hill-top campus above the city is an ideal one. Its remarkable success, however, is credited to the superior technical skill of the electrical engineering experts in charge of the operation of the station, all three of whom were pioneers in the wireless operating field and have constructed, tested and operated all manner of wireless sending and receiving apparatus. Prof. Wynant J. Williams is the engineer in charge with two instructors of the Electrical Engineering Department of the Institute, Harry R. Mimno and Leonard J. Inskip, as assistants. Rutherford Hayner is the program director and announcer.

Another "Farmer Program" from WGY

SO many requests have been received by WGY, the General Electric Company's Schenectady, N. Y., broadcasting station, for another "Farmer Program," that the studio management has arranged such a program for Thursday night, September 6. It is a novelty program, an evening in the country on the occasion of a fiftieth wedding anniversary. The Cornhuskers Orchestra will play and the Cowbell Four will sing. W. W. Norton, of Hartford, N. Y., will have a special message for the farmer and the city dweller in his talk on "The Class Conscious Farmer and Co-operation."

Sunday morning, September 2, WGY will broadcast the service of the First English Lutheran Church. The sermon will be delivered by the Rev. Herbert D. Shimer. WGY will not be in the air Monday afternoon, but at 7:40 p. m. baseball results will be announced and a concert program will be broadcast as usual at 7:45 o'clock. This program will mark the return of the WGY Orchestra for the season.

"Peg o' My Heart" will be presented Tuesday night by the WGY Student Players. The music, between the acts, will be provided by the WGY Orchestra.

At an early program Friday night a semi-classical program will be offered by Ernest Griffiths, tenor; Fred Grazaide, violinist, and John Finke, pianist. The 10:30 p. m. program of Friday will be made up of English compositions.

The Radio Dealer Year Book Will Appear October 1

THE Radio Dealer, 1133 Broadway, New York City, announces that it has in course of preparation the Radio Dealer Year Book which will contain information of vital interest to the radio business man This will include classified lists of manufacturers, list prices and trade names, a directory of radio trade-marks and a jobber's directory. The book will be published about October 1.

COMO DUPLEX TRANSFORMERS

The COMO DUPLEX SYSTEM of audio-frequency amplification gives the maximum volume without distortion and tube noise.

Type "I" Type "O"

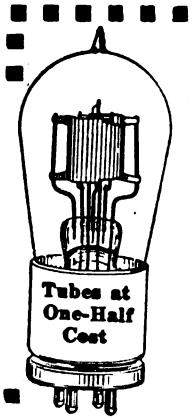
COMO APPARATUS COMPANY
446 TREMONT STREET BOSTON, MASS.

There is a combined filtering action which assures perfect results when ordinary amplification fails.

It can be added to your present amplifier, giving you power amplification on the weak signals that more of the ordinary amplification would kill.

Sold only in matched Pairs, $12.50

A copy of C. White's "HOW TO MAKE A POWER AMPLIFIER" is yours for the asking.



IT HAS HAPPENED TO ALL OF YOU IN A FRACTION OF A SECOND!

WHEN the filament burns out, at least $5.00 goes with it to put the set in operation again.

WHY not save nearly one-half the cost of a new tube by sending us your burned out or broken tube to be repaired?

WE REPAIR EVERY TYPE OF tungsten wire filament receiving tube. All our tubes are TESTED and GUARANTEED to function as well as when new.

All tubes returned P. P., C. O. D.

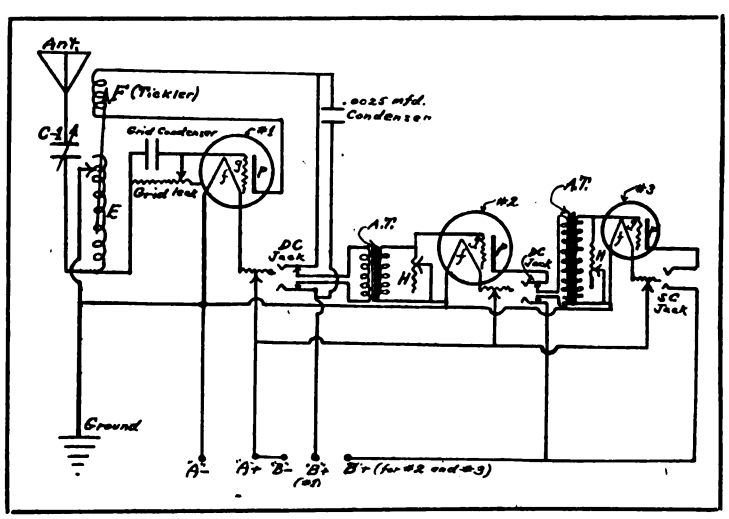
A UV199 Outfit Complete for $20

By C. White, Consulting Engineer

RADIO supplies are getting cheaper and better day by day and in every way. There is hardly any conceivable reason my every one should not have a radio set in his home and enjoy the many benefits to be derived from it. A year or so ago there were many obstacles in the road to the man who wished a radio set without any trouble or maintenance. It was next to impossible at that time to obtain a dry cell tube, and a storage "A" battery was the only economical thing to use. This meant not only the purchasing of a storage battery which in itself is quite an item of expense but also the trouble to keep the battery charged and in good electrical condition. Since last year a new tube has been developed and it is this new tube called UV-199 or C299 that has made it wholly possible to build a high grade outfit without worrying about a storage battery or rectifier to charge it.

With these new conditions in sight I have been asked by many to design a reliable tuner that would operate a loud speaker on local or strong signals. The result is the old reliable single circuit regenerative receiver with a few improvements in the amplifier circuit. While I must admit that such a circuit is not the best, it does represent a good circuit for the amateur who wants a complete outfit that will work without playing around with too many adjustments. It is not only simple but fool-proof to the highest degree. Trouble can be easily located and remedied by the man who builds it, and with care in operation you are sure to pull in distant stations with clarity and volume.

The coupler E-F as used in this circuit is not the molded type or the 180 degree type but the simple tubular type with the rotor mounted at one end of the tube. Such a coupler is less expensive than the other styles and can be used to good advantage in this circuit, although if it is so desired the molded or the 180 degree type can be employed instead. The tubular style of coupler generally has the small, or few number of turns, taps at the upper part of the tube, which is at the end of the tube nearest the rotor. Therefore by connecting up the coupler as indicated in the schematic diagram you can make use of this fact to slightly vary the tickler coupling in order to try different amounts of regeneration. It is plain to see that if the stator connections were reversed the inductance taps would be at the far end of the tube from the rotor and would only have a slight effect upon the rotor or regenerative adjustment. But care must be exercised to see that there are at least 40 turns of wire on the rotor to insure regeneration at all wave length ranges of the tuning circuit. Another feature of the set is the use of a leak resistance across the secondary of the amplifying transformers A. T. This resistance (H) is of the pencil gird leak with a variable resistance from 1,000 to 100,000 ohms, which can be readily purchased from any radio dealer handling variable leaks of the pencil style. The audio-frequency amplifying transformers will operate very much quieter with a variable leak since the input impedance of the amplifier circuit is fixed at a definite value and is not allowed to vary according to the insulation resistance and the leakage of the wiring. It is true that volume will drop just a little but the sacrifice is well worth the gain in quality and clarity of the music and voice signal.



A single circuit diagram using the UV199 or C299 tube. Note the variable high resistance leaks across the secondaries of the two amplifying transformers. These assure quiet operation and less distortion.

The jacks on the detector (No. 1) and the first stage (No. 2) are marked with the letters DC which means that they are double circuit jacks, while the jacks on the last stage (No. 3) is marked SC for single circuit or, as often called, open circuit jack. The convenience in operation afforded by the use of jacks is well worth the time and expense to install them. There is another feature I wish to call to your attention and that is the fact that the grid return from the detector tube (No. 1) is attached to the negative side of the filament. This is just the opposite to the instructions given with each

Geological Survey Takes Radio Set Into the Grand Canyon

By Carl H. Butman

EQUIPPED with a special radio receiving set, a party of ten explorers from the Geological Survey left Lees Ferry in Northern Arizona on August 1, for a three hundred-mile trip down the Colorado to the mouth of the Virgin River at Rioville, Nevada.

Unfortunately these modern surveyors, who are following the route first explored by Major Powell fifty-four years ago, were unable to carry a radio transmitting set due to weight and space. But they are carrying a modern receiving set and will be able to hear what is going on in the world during the next three months, although they will be unable to return daily their adventures in mapping this stretch of the Colorado. Arrangements have been made, however, with the radio stations of the *Deseret News* of Salt Lake City and the Los Angeles *Times* to broadcast bulletins sent from trail crossings. The dispatches will be relayed by runners and telephone or telegraph when the party gets far enough down the Colorado to reach the regular lines of communication. In this manner the world will be advised of the progress of the exploration in the Canyon and passage of the four boats through some of the wildest rapids in the country.

The special radio set was re-constructed by Mr. R. L. Atkinson of the Survey, from a standard Westinghouse regenerative set, adapted to two stages of amplification with new tubes. The whole outfit, including the batteries, is packed in a water-proof, wooden box with sponge rubber to keep it from jarring during the long boat trip. An especially constructed antenna on a reel, capable of being erected at camp sites on the banks of the river, can be strung from short poles or from projecting rocks to a length of 150 feet.

A preliminary radio test at Lees Ferry has already been made, and it is reported that the explorers received broadcasts from Los Angeles, 430 miles away, without difficulty at night. The real reception test Col. C. H. Birdseye, who is in charge of the party, believes will come when they are in the lowest part of the Canyon, estimated as a mile deep, near El Tovar, where dead spots and static may be encountered.

Besides the geological and topographical results achieved, the trip will also prove of material interest in the development of radio communication, along with experiments undertaken by the Bureau of Mines, and other governmental bureaus, to see how far radio will carry into the "bowels of the earth."

Cheap—But Not Tinny

MANY fans want a loud talker but can't afford one, and therefore they use tin horns with loud speaking unit phones. If you get a megaphone, the fibre kind that the cheer leaders use, and put it over the phone, you will be surprised at the clearness and lack of tinny sound. And furthermore it works fine.

(*Concluded from preceding page*)

tube, but I have found that better results are obtained when the return is made to the negative side instead of the positive side of the "A" battery. If you wish to find out for yourself you can easily transfer the connection on the detector grid return to the positive side which is shown in dotted lines on the diagram. Be sure to purchase a 30 ohm rheostat for each tube. A 6 ohms rheostat will not work with the new tubes since it does not afford ample control of the filament current. The tube sockets should be mounted on thick felt and the wire connecting directly to the sockets should be flexible in order to cut down microphonic hum from mechical vibrations and jars. Complete shielding of the panel is not necessary, but it will be of advantage to place a small circular shaped piece of copper foil, which is connected to the ground, on the front side of the condenser C-1. C-1 is a 23 plate variable condenser with a vernier attachment of some sort. In connecting this condenser in the circuit be sure to see to it that the movable plates of the same are connected to the Ant. terminal of the set so as to avoid placing grid potential on the shaft of the condenser which might cause howling while tuning in. All joints should be well cleaned and soldered. Avoid using too much solder and splattering the solder and the soldering flux on the panel and other parts of the set where it is not needed. You have no idea how much howling solder flux on the panel and just how much trouble a small lump of solder in the wrong place can cause. The outfit is a most reliable and fool-proof set and the only test that will be required before it can be operated is the regenerative test. If the tube (No. 1) refuses to oscillate as the coupling between the tickler and E is increased then it is advisable to try the following suggestions: If you are using a 180 degree coupler reverse the terminal connections to the rotor. When an ordinary 90 degree coupler is used this is not necessary since the coupler can be turned completely around on its axis as a general rule. Adjust your grid leak resistance, perhaps you have not the correct value for the tube used. Try varying the filament current but under no circumstances place more than three dry cells on for "A" battery to light the filament. Next raise your "B" battery voltage until the tube oscillates. If all of these fail try another tube in the detector socket, sometimes one tube will act better as a detector than the others although they belong to the same type. When tuning in place the rotor almost vertical with respect to the stator, adjust C-1 and the taps on E until the faint trace of a signal is heard. Then increase the coupling of the tickler by slowly turning the tickler (rotor) in the direction that increases the volume and at the same time slightly altering the setting of C-1 to compensate for the changes in the circuit constants due to the movement of the tickler. When you reach a point where the music or voice grows very rough or hollow, then you have too much regeneration and it is better to turn your filament down a little or take back on the coupling. If the regenerative point is over-stepped the tube will oscillate, which condition is noted by a click in the phones followed by a rushing sound like the escaping of steam. Try to tune in without creating this condition. The parts for this set complete, without tubes and batteries, will cost from $20 to $30 depending on the quality.

A Simple Radiophone for Local Work

By Carl Masson

ANOTHER big radio season is before us; in fact, judging from the preparations which manufacturers are making, this coming season will by far outclass all previous ones. What is more, thousands of radio fans who had heretofore been termed as "broadcast listeners" are swiftly becoming radio amateurs.

What is still more, many amateurs, who have mastered the art of producing sounds from ether waves, will want to generate waves of their own. In other words, hundreds of radio stations will install equipment to "talk" in addition to receiving sets, and the radio inspectors will have to issue many new licenses.

With these predictions in mind, the author presents herewith a radiophone transmitting outfit of unusual simplicity, and costing very little to make.

The days of the spark coil sets ("squeak boxes") are gone forever, and C W affords wondrous opportunities for the amateur to smash all records.

The accompanying illustration, which appears to be a receiving set, shows the layout of the parts comprising this outfit. The loose coupler is a medium-sized one, the variable condenser is .001 in capacity, and is preferably an enclosed one. A standard V. T. socket, an ordinary filament rheostat and binding posts as marked, plus the microphone, tube, and batteries, are the few parts required. All parts are mounted on a woden base as shown in the illustration.

The tube used is one of the hard amplifying type. The "A" battery is the regular six volts. Four "B" batteries connected in series supply the plate voltage.

An antenna of the "T" type will give the best results for transmititng. Tunning is accomplished with the loose coupler and the variable condenser. Rough adjustments are made with the coupler and fine tuning is done with the variable condenser.

Though the transmitting distance of this outfit is limited, it is ideal for the beginner. The diagram shows how the instruments are hooked up, which, I am sure, is self-explanatory, being so simple.

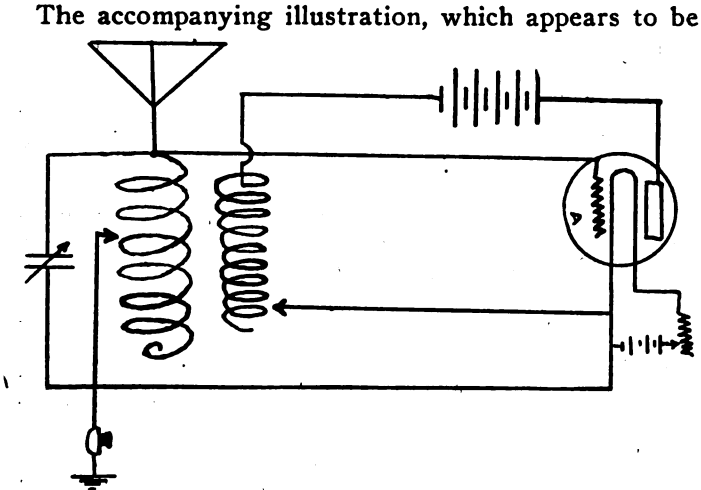

Fig. 1. Circuit diagram for a simple home-made radiophone.

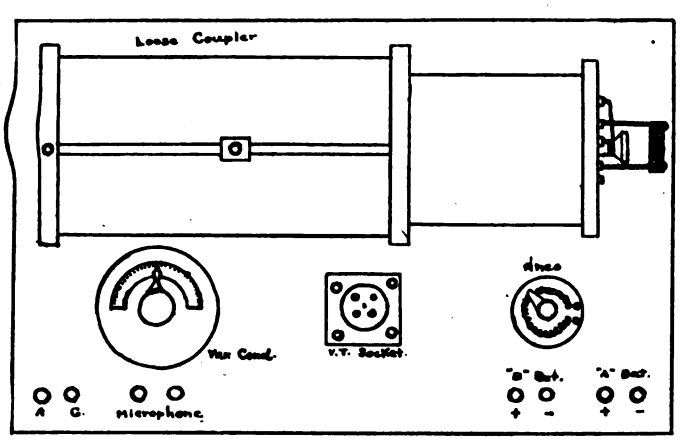

Fig. 2. Suggested location of apparatus on baseboard.

500 Miles on an Indoor Aerial

By Arthur G. Shirt

MANY radio enthusiasts who find it impossible to rig up an outdoor antenna have given up the idea of owning a radio receiver for themselves because they doubt the efficacy of an indoor aerial. The average loop aerial, of course, is almost out of the question for the radio novice, because its use demands very sensitive receiving apparatus of a make and cost far in advance of the humble desires of the average owner. With a single tube set, a loop is a very critical aerial, and can be successfully operated only with a few special hook-ups and then with more than ordinary skill and care. But with an indoor aerial of the type described below, all these disadvantages are done away with, and concerts come through with the clearness and volume of an outside aerial.

Many amateurs use the lighting circuits of their homes as radio antenna. However, it is not necessary to use a condenser plug, as recommended by most users of the lighting circuit antenna, if you take the radio impulses from the circuit by inductance. Running from the aerial binding post on the panel, use an ordinary piece of lamp cord—that is, two pieces of insulated wire twisted together. One wire is connected to the inside connection of the light socket, the other end of the same wire being taped very securely to prevent a contact with the set. The other wire connects to the aerial binding post, and the unused end of this wire is also taped to prevent contact with the light socket. With this arrangement, there is no direct connection of the set with either of the two wires of the lighting circuit, yet the device works, and it works well. The originator of this system says that his set is almost noiseless and that stations which before came in weak now come in loud and clear.

The current is always turned on while the set is in operation, but, of course, there is no consumption of current. The average working range of a single tube regenerative outfit, using the lighting circuit as suggested above, is 500 miles. There is no danger in this novel arrangement, either to the lighting system of the house or to the radiophone receiving set.

Direct Radio Service to United States from Holland and Italy

By J. L. Bernard

FOR the first time in the history of international communications, direct radio telegraphic service between the United States and the Hague, Holland, and between the United States and Caltano, Italy, was established last week according to an announcement made by the Radio Corporation of America. The opening of these services raises the total number of direct radio circuits radiating to European countries from New York City from six to eight circuits and affects not only Holland and Italy but provides more direct routes between the adjoining countries and the United States.

The addition of these new circuits to the already existing channels of radio communication to many parts of the world materially advances the status of plans which are now being worked out by the Radio Corporation to make the United States the centre of a world-wide radio communication network. Because of the centralized location of the United States, with Europe to the east, South America to the south and the Orient to the west, this country enjoys a natural advantage which helps to make it possible to link the principal nations of the world by radio around New York as the pivotal centre. This plan is rapidly nearing completion, there being at present eight connections across the Atlantic and one bridging the Pacific.

The circuit to Italy is one of the longest in existence. The distance which the radio waves travel in connecting the two points in communication is over 4,500 miles, or one-sixth of the way around the globe. In bridging this distance, however, the element of time is a negligible factor, it requiring but one-fortieth of a second for the signal flashed in New York to reach Italy. The distance traveled by radio waves between the United States and Holland is 3,500 miles.

The Italian Government has for many years expressed a desire to have direct radio service with the United States. Not only will it be highly beneficial to that country, but Italy will now be in a position to render an effective service to neighboring countries by placing the use of her radio station at the disposal of Sicily, Hungary, Servia, Greece and other neighboring countries and thus provide more rapid and direct contact between these countries and the United States. The more intimate relationship created by the new radio service will greatly enhance the trade interests between all the countries affected.

The geographical location of Holland with respect to Belgium, Finland and Denmark gives to Holland a similar advantageous position whereby she may handle communications to and from these countries with maximum dispatch. Thus these two new radio stations provide an outlet for business and social traffic between many European countries and the United States, according this nation a unique and powerful position of commercial and political prestige in the affairs of foreign nations.

In commenting upon the new service General Harbord, president of the company, said: "Direct communication between the United States and Holland and between the United States and Italy has long been the dream of our friends across the sea. The opening of this remarkable service will link in a more perfect bond the business and social friendship of these peoples and will assist in bringing about the stabilization of trade conditions which depends so largely upon swift, reliable and direct communication. This achievement is a monument to the skill of the Holland and Italian Government engineers with whom our engineers have been closely co-operating for several months in an endeavor to perfect methods for annihilating space and time in the exchange of intelligence."

The transmitting station which engages in communication with the two stations abroad is situated at Rocky Point, Long Island, 70 miles from New York City. The antenna system of this central station is so large that a plot of 6,400 acres was required on which to erect the towers. A system of private telegraph lines joins the control apparatus of this station with the operators at the Broad Street offices of the Radio Corporation where the actual telegraphing is performed. The receiving station is located at Riverhead, seven miles east of Rocky Point, and in a similar manner the receiving operator at Broad Street receives the signals intercepted at Riverhead and transcribes the dots and dashes as they are received by him. This system of remote control of high power radio circuits is a strictly American innovation which obviates all the disadvantages of stations located in a city where various atmospheric disturbances seriously interfere with its efficient operation.

Reward for Message from Captain MacMillan

RADIO WORLD has received the following telegram from WJAZ, the Zenith Edgewater Beach Hotel Broadcasting Station, Chicago:

"MacMillan expedition has not been heard from since July 27.. Many are worried, but we do not think it strange, as his ship, 'Bowdoin,' is not only in continuous daylight but is inside auroral band. He will have no darkness until September. Reception is difficult for him under these conditions from low-powered transmitter necessitated by the limited space on his ship.

"However, we will present gratis to the first Canadian or American amateur to deliver to us the next message from Captain MacMillan a complete Zenith standard receiver and amplifier, a duplicate of the MacMillan set. This is done to electrify interest generally."

Don't Do It Half Way!

WHEN constructing a set you will probably carefully solder all connections, and then neglect to solder your antenna wire connections and ground connection. The energy picked up by the antenna is so extremely small that it is a waste of good work to put up a fine 100 or 150 foot antenna and then neglect to get even a quarter of the actual energy out of it by not soldering each and every wire, or else hand splicing them like rope. Don't do it only half way—go the entire route.

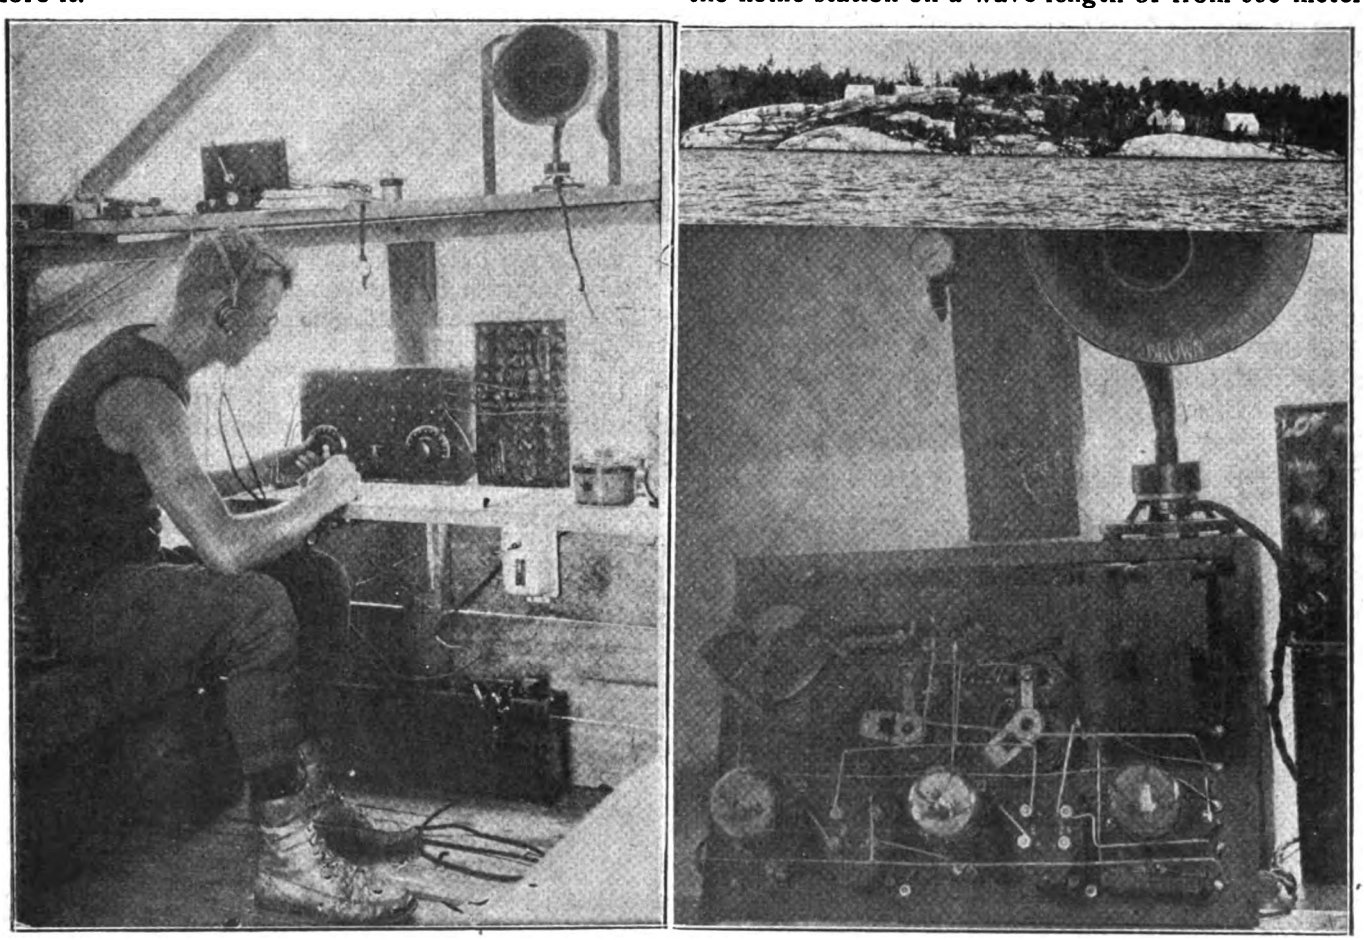
Fighting Forest Fires with Airplanes and Radio

By Campbell MacDougall

PROBABLY the most serious business in the Canadian wilds and forests is the fighting of forest fires. Canada employs a picked staff of men to watch out for fires in their great uncharted wilderness and fight them. Were these men not on duty, forest fires, due to lightning and camp fires left burning or smoldering, would devastate the vast forests of Canada in no time. A person who has never seen a forest fire cannot imagine the peril of it. It sweeps forward under a breeze like the hand of death destroying everything before it.



(C. Paul Thompson)

William Robinson and his receiving station on Ramsay Lake, Ontario, listening in for fire alarms. Receiving set designed and used by Robinson, and, above, the location of the station.

In order to cope with this terror, the Canadian Government has equipped her fire fighters with airplanes. These scout around, spot the fire and report it to headquarters at Ramsay Lake, Ontario. Up to a short time ago, the planes relied upon their speed coupled with manual signaling devices to advise headquarters. They would spot the fire, take the location and then fly post haste back to the station.

As an experiment they tried installing radio sending and receiving sets on the planes and at the station. The planes are of the SE type, and as yet not all of them are equipped with radio. The receiving and transmitting sets are located in the forward cockpit of the plane, and the antenna is of the hanging type used in most planes. Current for the operation of the sets is derived from a wind driven generator located on the wings of the plane.

William Robinson, who is responsible for the planes and rangers' offices being equipped with radio, is the chief radio engineer of the Laurentide Air Service. The sets were made by him and were specially constructed with a view of the service to which they would be put.

The method of fighting these fires is novel in itself, inasmuch as the planes themselves and their pilots cannot land in the heavily wooded sections. They call the home station on a wave length of from 550 meters to 900, advise it of the location of the blaze according to a map and then hurry off after getting an answer.

Then the rangers, who are scattered throughout the woods many miles from the station and may be hundreds of miles from the fire are called by line phone and start for the location of the fire.

Mr. Robinson's set is a regenerative receiver, consisting of detector with two stages of audio-frequency amplification. Because of the fact that the particular locality is a "static hole" it is impossible to use any additional amplification.

Besides being of value as a fire fighter, radio also relieves the terrible loneliness for the rangers. They beguile their dull nights by listening into the local and distant broadcasting stations, while waiting for their radio call to duty.

Swallows Interfere with Broadcasting

By Washington R. Service

EVEN the birds in Washington, D. C., are radio fans, and their insistence upon attending broadcasting events is causing some of the local stations considerable embarrassment.

Engineers of the Chesapeake & Potomac Telephone Co., broadcasting station WCAP, found themselves in difficulties during the broadcasting of the dinner given to Paul Whiteman in New York, received there by land wire from WEAF, because of the antics of swallows which had settled upon the station's antenna.

Shortly after the program began the wave length of the station suddenly increased from 469 to 479 meters, the vacuum tubes in the transmitter began to heat up and the plate current increased tremendously. In order to save the tubes it was necessary to reduce the plate voltage from 1,600 to 1,450 volts, but even after this reduction was made the plate current was 850 milliamperes instead of the normal 700 milliamperes.

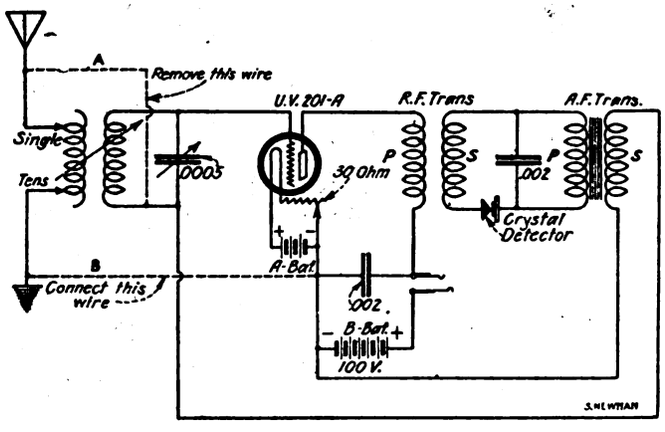
Emergency apparatus was placed in readiness for immediate use, as the engineers scurried around seeking the cause of the trouble. One of the men went out to look the antenna over, and almost fainted to see a flock of swallows calmly roosted on the wires. The lead-in wire was shaken sufficiently to cause the unwelcome radio fans to seek some other resting place for the night, and conditions in the operating room returned to normal.

The experience is believed to be new in the history of radio broadcasting. Engineers of Station WCAP explain that the size of the antenna was increased by the size of the birds' bodies, thus increasing the wave length and causing a greater current to flow. They deny, however, that the birds were attracted to the antenna for a feast of mythical "wire worms" or that they are in the market for a radio scarecrow. Inventors are said to intrigued by the possibilities of the case.

Curing Induction in a Reflex Set

By Earl A. Wright

AFTER having constructed an Erla reflex circuit, as invented by the Electrical Research Laboratories, I found it to be the best little one tube set I had ever tried. The tone and volume was equal to two tubes, but the circuit was very noisy, due to the electric light wires. This caused a very disagreeable hum in the phones, and it was loud enough to hear all over the room.



Easy method of curing induction in a reflex set.

I tried to rid my set of this noise by moving it to different parts of the house. The noise always pursued me. Then I opened the light switch outside, and the hum stopped and everything became as clear as a bell. This showed my set to be picking up the A. C. induction from the wires in the house. The closest wires were about 20 feet from my set.

I had been watching the question and answer department of all the radio magazines I could get, thinking I could find the answer to my trouble. Many times I ran across the question "How can I stop the hum in my reflex set?" and the answer was, "Run your aerial at right angles with the power wires." This, of course, would help if the aerial happened to be close, and running parallel with the wires. But it didn't answer much for me. Grounding the negative side of the A battery will stop the hum in ordinary circuits, but grounding the A battery in this particular reflex circuit would unbalance the whole thing.

Finally I stumbled across a way to stop it. It was so simple and easy, and worked so well, I thought there must be many reflex fans throughout the country who would be glad to try it, so I am giving the little secret to RADIO WORLD. Of course, I do not know how it will work on other reflex circuits besides the Erla. But I think it will be about the same.

It is only necessary to change the circuit slightly, as shown in the diagram. Remove wire "A" and connect wire "B" in the circuit. That's all there is to it. The set will now be very quiet, and everything coming in will be as clear as a bell. This circuit, if properly adjusted, will operate a loud speaker.

Radio a Boon to Alaskan Light Keepers

RADIOPHONE communication between light stations in isolated territory has been found very successful by the Lighthouse Service, according to reports to the Department of Commerce. Complete stations were installed at Cape Sarichef and Scotch Cap Light Stations, Alaska, in 1921, and after overcoming some difficulties of operation during the first year, due to burnouts of the motor-generator and wrecking of one of the steel antenna masts by a storm, communication between the stations has continued uninterruptedly for the past year, which has been mild.

The two stations are about 17 miles apart. Keepers at both station have mastered the code, so as to be able to exchange messages with mail steamers, and have been able to communicate for a distance of 65 miles by voice and 165 miles in code. The telephone installation at these stations consists of a type C. W. 936 short range radio telephone set, two three-fourths K. W. 32-volt Delco engine-driven generators, two 70 ft. steel poles and the antenna and ground system.

Here's a Great Loop for a Crystal Set

By Kenneth Malcolm, A. I. R. E.

WHILE visiting a friend in Brooklyn, N. Y., the other evening I was asked to listen-in on his radio set. Immediately upon donning the receivers I could hear WOR broadcasting a very fine 'cello solo. The clarity and the audibility were remarkable, and I asked my friend what kind of a tube he was using. He replied that he wasn't using a tube at all, but a galena crystal. Noticing the unusual freedom from static on such a hot night, I inquired the

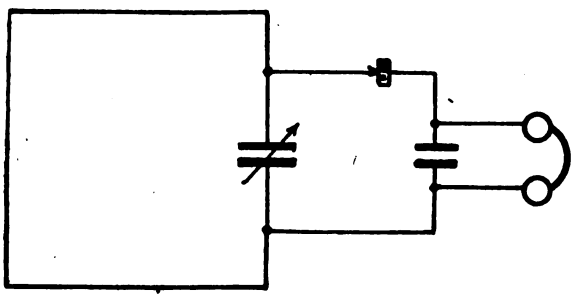

Fig. 1. Circuit diagram for a crystal receiver using a loop antenna as described in the accompanying article.

type and size of the aerial. To my surprise, I learned that there was no outdoor aerial at all, a large loop indoors doing the trick.

Immediately I thought I should tell the readers of RADIO WORLD about this feat, so that those who had crystal sets could make good use of the idea during the summer months. Before, I had been rather shaky about recommending loops for crystal set users, but now I give them whole-hearted endorsement. Of course, they cannot be expected to give the results of

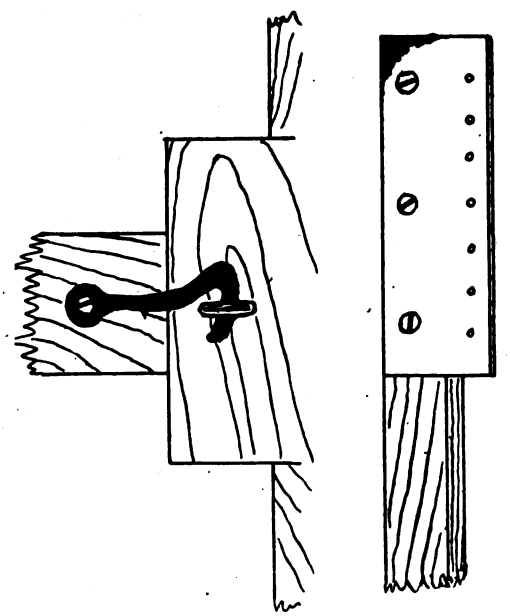

Fig. 2. Method of fastening cross arms so as to keep them rigid when used, or allow them to be conveniently folded. Also details of bakelite strip used for supporting wires.

an outdoor aerial, but for sets that are within ten or fifteen miles from a broadcasting station, they would probably allow good reception at times when by other means it would be impossible. The secret of the whole affair is to get the loop large enough for fair efficiency. The loop mentioned was rather cumbersome, and in the way when not in use, but the one to be described will for the most part do away with that disadvantage.

Secure four lengths of wood 3' long, 1" wide, and ½" thick. Also, a good hardwood block 2½" square and ½" thick. Purchase four brass hinges having a width of an inch, and four flat hooks with eyes to match. Four strips of bakelite ⅛" thick, each 1" wide and 4½" long, and about 140 feet of wire, completes the material list.

Sandpaper the wood strips, and see to it that the ends are perfectly square. Now you may give them a coat of stain of the desired color, and then several coats of shellac or transparent varnish. Do the same with the center block. Next you may fasten a hinge to one end of each of the strips; do this so that the hinge may double up toward the part that is fastened. The correct way is shown in the accompanying drawing.

Now take each of the bakelite strips and drill a series of seven 1/16" holes, ½" apart in a line ¼" from one of their edges. Near the other edge, drill three holes to take the fastening screws. When this is done, one may be screwed close to the outer end of each of the strips, with the edge having the seven holes, pointing toward the face on which the hinge is fastened.

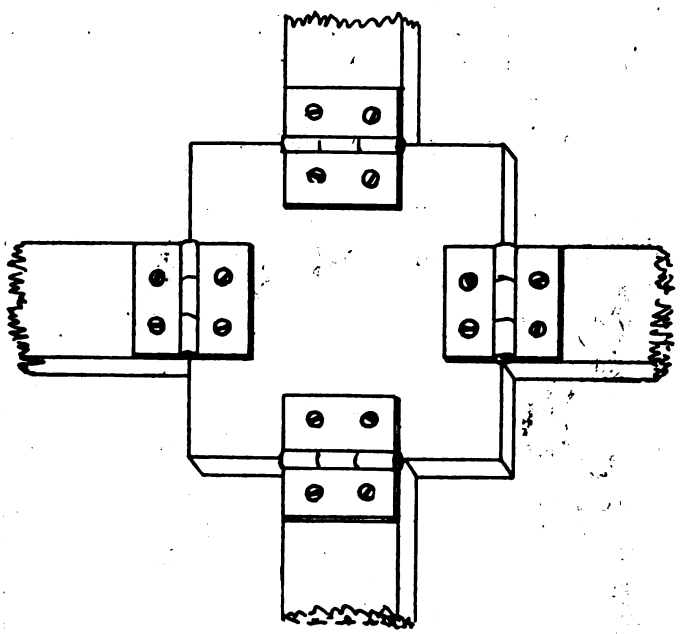

Fig. 3. Manner of placing hinges on ends of cross arms and center piece to allow them to be conveniently folded when desired.

The other ends of the strips may now be fastened to the center block as shown. The ends of the strips should be tight up against the edges of the block. Turn the whole affair over, and on the other side of each strip, fasten a hook and a screw eye so that the loop frame will be held open and rigid when in use.

The wire may now be threaded through the holes. There should be seven turns in all. Most any wire will do for the purpose, but a stranded wire such as lamp cord or Litzendraght would be the best. If you use lamp cord, it might be necessary to make the holes in the bakelite strip a little larger.

On account of its large size, it will be found that the loop can usually be better suspended from a chandelier or something of the sort, than mounted on a base; and

A Literary Broadcasting Station

By A. Stone

THE literary world has one of the most powerful allies on its side in the form of radio. Through the means of this remarkable invention of man there is no work of pen that is not within the reach of any person who is fortunate enough to own a radio set. It has often been said that the price of important literary works has been prohibitive for the person of small means, that libraries do not often extend the proper facilities for placing the books most in demand before those persons who frequent them, but it seems to me that radio, with such an elasticity of range quite easily overcomes these two main objections.

When broadcasting stations begin rendering such service as quoting from Shakespeare, reading from the Bible, announcing in serial form Well's Outline of History or reciting from Kipling and other famous poets the general public will quickly realize just how important radio is in disseminating literary information broadcast.

At the present time the various broadcasting stations are now rendering a diversified service—that is, their programs not only consist of music but of sports, news, lectures and any other items that might be of interest to the general public. As far as I know there is yet to be established the first broadcasting station that deals exclusively with one subject. There are no broadcasting stations that send out news exclusively; there are no stations that devote their activities exclusively to music; there are no stations that devote themselves exclusively to lectures.

The station that I am to construct at Milton-on-the Hudson, N. Y., this fall will be a new departure in broadcasting. I am going to use it exclusively for literary purposes and lectures. I will invite the most eminent men and women I know to visit the station and to talk on famous books and other literary subjects. I shall also try to have authors read their own original works for the benefit of the large radio audiences that I know would be willing to set aside a few hours each week to listen in on subjects pertaining to literature. From time to time I also plan to use the broadcasting station for the purposes of lecturing on some popular subject pertaining to literature.

There have been so many inquiries coming to my home concerning the broadcasting station I am preparing to build, as the result of the wide publicity the original announcement received through the columns of RADIO WORLD, that I am once more taking advantage of this opportunity to state that the station will not be in operation for several weeks as I am still obtaining data that will enable me to establish a station of sufficient power to answer my purposes. I hope, therefore, that the many radio enthusiasts who have written me commending my efforts to establish a broadcasting station with such worthy purposes in view, will be patient.

"Radio World's" Transcontinental Tour

Arthur G. Shirt and RADIO WORLD'S Transcontinental Touring Car.

UNKNOWN to our readers in general, RADIO WORLD went on a transcontinental trip this summer in the person of Arthur G. Shirt, friend and radio adviser of thousands of our readers, and "Radio World," the car.

How this was done is easily explained by the photograph. A. G. Shirt and "Radio World," the touring car, traveled across the United States via the Lincoln Highway, a distance of approximately 4,500 miles. Many people met both the voyagers and after knowing them embraced them in a truly long lost friend manner.

It is said that "Radio World" appealed to everyone, its pleasing personality, and never-tiring "voice" appealing and enlightening approximately 5,000,000 people as to the whereabouts of the best radio weekly.

Mr. Shirt is returning, browned and happy, from a summer in the great outdoors. He says he feels like a two-year old and is "rarin'" to go back to writing.

(Concluded from preceding page)

this easily may be done by fastening a screw eye in the end of one of the wood strips, and fastening a cord through this. When not needed, the loop may be folded together and stowed away in the corner of some closet.

With the loop described, an entire receiving set is not necessary, but simply a variable condenser, a crystal detector, a phone condenser, and a pair of phones. They should be connected up as shown in the circuit diagram.

To get your station you simply adjust your detector, slowly turn the loop, and adjust the variable condenser; nothing could be easier. If you have all good parts you ought to get really surprising results.

Such a large loop could be used also with a single vacuum tube to advantage. The hook-up to be used in this case would be the same as that published in RADIO WORLD for May 12, 1923. Here you would get almost as good audibility as if you were using a long outdoor aerial, and the selectivity would be much improved.

Large loops are not quite as directional as small ones and the tuning is not as sharp, but they offer more surface to the incoming waves and hence their energy absorption is greater. The effect of this is more pronounced in the case of crystal or non-regenerative sets.

Government Radio Work Needs More Money

By Carl H. Butman

WHEN the next session of Congress takes up for consideration the appropriations to be made for the conduct of the Federal Government during the coming fiscal year, a greatly increased appropriation will be asked for the operation of the Radio Division of the Department of Commerce, which today is struggling along on funds but little greater than those available three and four years ago when broadcasting, as we know it today, was non-existent.

If the Radio Division is to perform its functions efficiently, at least $100,000 more than is now appropriated will be necessary, it is believed. A greatly increased force of inspectors is needed if the broadcasting stations and amateur plants are to be checked up properly. At present practically all of the time of inspectors on the coast is required for the inspection of ship stations and similar government work, and they are hard pressed for the time in which to make these necessary inspections of other stations. The recent re-allocation of wave lengths, however, makes it necessary that every station be extremely sharp on its wave, if there is to be no interference, and careful checking up of the wave length used is necessary.

Few persons not connected with the work of the Department of Commerce realize what the district inspectors are doing. Many of them are out of bed and ready for their day's work before the last "ham" has signed off for the night. They travel great distances; most of them have automobiles for facility in covering their territory and run the speedometer up many thousand of miles in the course of a month. All sorts of work come to the radio inspectors; the checking of broadcasting stations and the inspection of ship plants is but a part of their labor. Many complaints are received, some well founded and some imaginary; but all must be investigated, at a great expense of time.

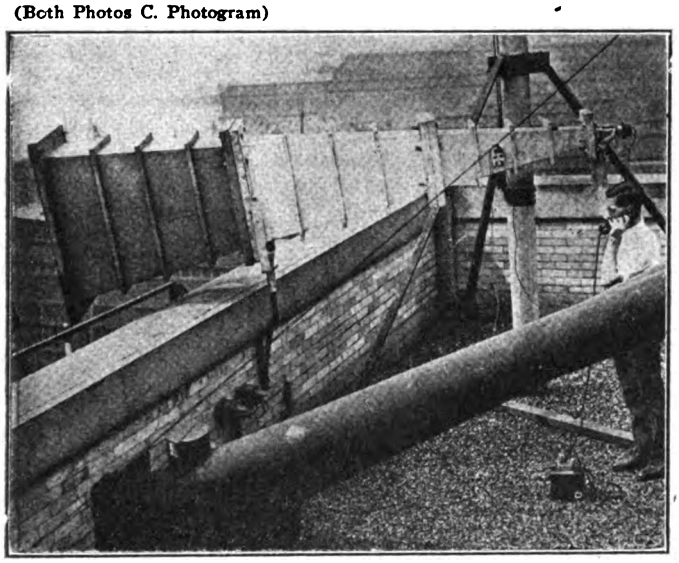
Practically every inspector is overworked, and it is the desire of officials in Washington to give them such assistance as may be necessary for them to carry on all of the many operations which go to make up an inspector's day. At the same time the Washington offices are none too well supplied with labor, and hard work and long hours are necessary for the handling of the great mass of data, reports, complaints, letters, applications, etc., which pour in in a steady stream.

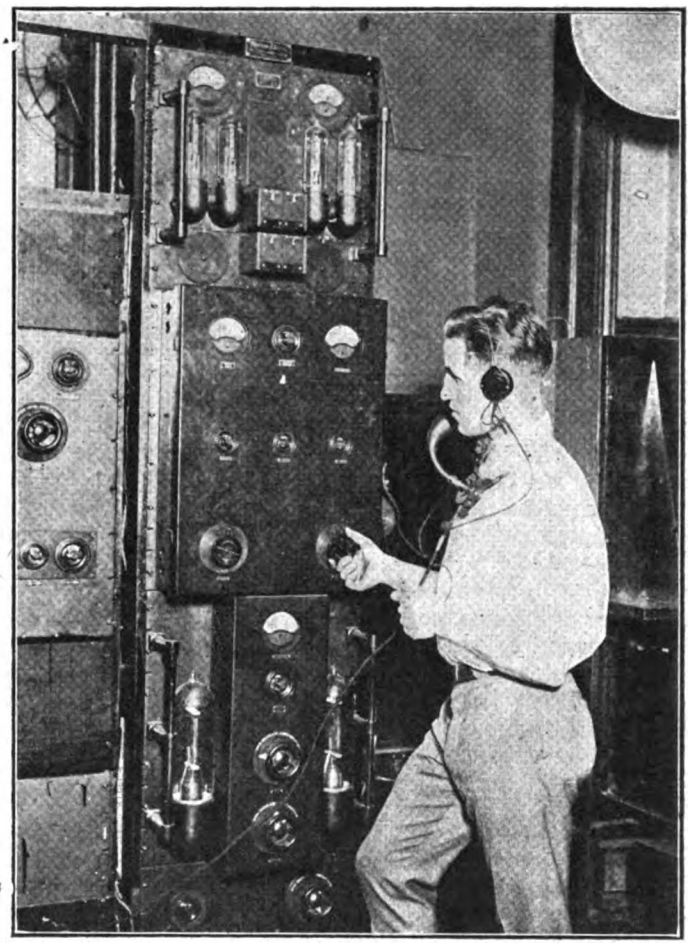
Western Electric Roars Farewell to Holmgren

BY means of the huge amplifying horn and speech amplifying device located at the Western Electric Company's plant on West Street, New York City, the officials of the company were able to say farewell to A. Holmgren, Director of Research of the Royal Swedish Telephone and Telegraph Company, after a visit to the Untied States.

The illustration at the left shows the huge 10-foot horn which carried the voices across the river to the boat on which Mr. Holmgren was sailing. The power amplifiers used are shown at the right.

(Both Photos C. Photogram)





Makes It Work Smoothly

A LITTLE vaseline lightly rubbed on the switch-points of the receiver will make the arm slide easily over the points and obviate any chance of friction wearing the points down. The fact that it is an oil base product does not affect the electrical contact in the least, but if anything, makes it better. Along the same time, a drop of oil on the bearings of the condensers makes the rotor turn smoothly, if too much is not put on.

Radio for the Farmer and the Rural School

By Kenneth M. Swezey

THE greatest hindrance to development and civilization is isolation. Africa is in the place she is now in today because of her previous inaccessibility. China, Persia, and the rest of the Far East are mouldering in the remains of a civilization of centuries back, simply because they shut off the rest of the world with its new ideas. The farmer of our own country has until recent years been held back by the same conditions, by the separation from his city brothers necessitated by his location and inadequate means of transportation and communication. The extension of the railroads offered him his first chance to keep pace with the outside; and the automobile increased this possibility manyfold. Today, radio broadcasting makes the link which—in addition to the railroad, automobile, and telephone—gilds the farm as attractively as it does the city. The farmer needs no longer be bored by solitude, miss the frivolity of city life, lose crops on account of insufficient information, nor be deprived of a high grade education. The acquisition of a radio receiving set will bring knowledge, entertainment, comfort and pleasure right into his home.

Just what can radio do for the farm home, and what are the easiest means to the end? First of all, a radio set would be a social advantage. It would acquaint the rural citizen with the doings of his neighbors and his friends of the city. It would bring to him the music, the literature and the wisdom of the outside.

Who can repress the thrill that come when listening to the sextet from "Lucia," the purifying quiescence of a violin rendering of Massenet's "Elegie," or the longing remembrance occasioned when a soft but mellow tenor voice carries the strains of "When You and I Were Young Maggie"? The classics in music are character builders beyond the shadow of a doubt. Yet, before this time, what chance had a farmer to hear an opera, or even a selection from one, except on the phonograph? Now, things have changed and he has but to tune in to get the food that will feed his deeper self and make him a better and stronger citizen.

The younger generation of the country are as much addicted to jazz as are the finale-hoppers and flappers of the city. And radio affords an admirable means to keep them in their own community by bringing to their Town Hall the famous jazz orchestras of the big cities. It also keeps them posted on popular music.

Radio bring the governmental representative and the others in office and introduces them to the farm. No longer can the farmers be hoodwinked and dumswiggled into voting for some one they do not know, on the basis of soap box orations and unscrupulous mail propaganda. Radio puts them in direct touch with the administrators whom they pay to look after their welfare and the whole business becomes personalized and "man to man." The wideawake man on the farm, with his radio set, can be much more well informed than can an indifferent man in the city.

To those in the more remote localities the Sunday radio services are a boon. Deprived of all but an occasional attendance at church, the isolated farmer rejoices at a chance to hear the hymns of his faith sung by noted soloists, or famous choirs, or played by an artist on a priceless organ, to hear an inspiring sermon from the lips of a worthy preacher. All this is something new and wonderful to him.

Even in small communities where they have a church, the members are not always able to pay a regular minister or to pay for any music, save that which is furnished from among themselves. Here, a radio set with a loud speaker serves effectively. Either it replaces a regular minister entirely, or is used in emergencies.

Radio has also a great educational value. Listen in on any program, and you will usually find that some educator has been included, someone who will leave you with more knowledge than you had before. Possibly it is an explorer who has just returned from the heart of Africa who tells of the animals, the vegetation, and the living conditions there. It might be some scientist trying to explain the Einstein relativity theory. Or it might be some teacher leading his radio class in the more practical study of stenography, language, domestic science, or one of a thousand other things.

As an adjunct to the rural school the value of radio cannot be overestimated. Just as a distant minister can be brought to the church, so can a teacher be brought to the school. In fact, a different teacher could be procured for each subject, whereas formerly a single resident teacher had to do all the work as best he could. When a definite system has been worked out, a staff of competent teachers could be kept at central points, and their instruction could be broadcast to all the small schools within hearing distance. A single teacher could be kept at these small schools to offer whatever personal guidance is necessary. In this way the expense would not be materially increased, and at the same time the pupils would be getting the best of high grade instruction. Of course, the resident teacher cannot be entirely dispensed with, but radio can bring personalities into the classroom that would not otherwise be available.

A class on civics could be taught admirably by radio and the leaders of the country could themselves be the teachers. What would inspire patriotism in the hearts of the country's youth more than to hear the voice of the President, his cabinet, and the minor executive and judicial heads? Soon Congress will be hooked up to a broadcasting set and the proceedings, as they occur, will be broadcast to the country. Important conventions and the like will be broadcast also.

Radio music could be well brought in as a part of the school curriculum. It would acquaint the pupils with the composition, composers and musical artists of our nation and of others.

Economically, radio is in to do its part for the farmer. It is the speediest and most accurate crop bulletin that ever was or ever will be devised. The Department of Agriculture sends crop reports daily from a number of big stations, covering territory all over the country. This is of inestimable value. Then, too, the weather reports that are sent out daily are not to be disregarded. These help the farmer to "make hay while the sun shines." One writer has recently acclaimed radio as the "Voice of God" to the farmer. Whether it be this or no is not to be disputed, but it certainly is becoming a beneficent and indispensable part of farm life.

Is it possible for every farmer to own a radio set in the near future? Yes, it is possible. And as soon as they become innoculated with sufficient virus of radio bacilli, and fully understand their possibilities, they will have them. There is no doubt about it!

A Home-Made One-Tube DX and Loud Speaking Receiver

By Byrt C. Caldwell

THIS receiver is an especially good model of the reflex receiver which is so popular now. To the owner of a regenerative set the reflex is a revelation. There is absolutely none of the howl which is so apparent in regenerative sets. When tuning, there is no whistling of the carrier wave and no distorted tones. Music and voice are tuned in strong and clear without the troublesome work of clearing out the "music" which is experienced by most fans. The quality also surpasses that obtained on the regenerative receiver. Control is much simpler and the reflex is much more sensitive than the regenerative receiver. By all this I do not mean to belittle the regenerative receiver. Wonderful results are, of course, obtained on this set by an experienced operator, but for the beginner the reflex is undoubtedly the best—for him and for his neighbors.

The writer designed and built the receiver which is described here. There is some slight variation from the standard reflex circuits but these changes are for the better.

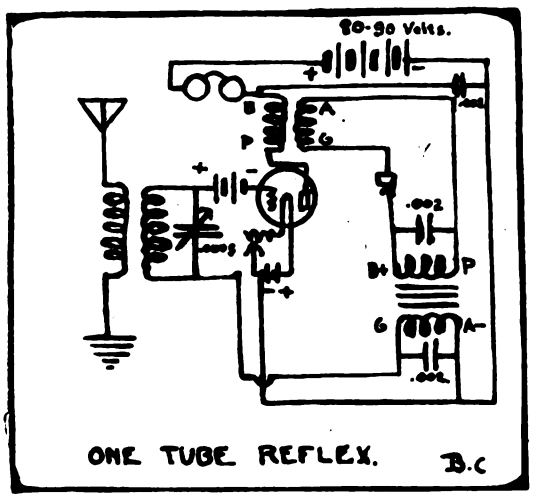

Fig. 1. Schematic diagram of a one tube reflex that can be made to work a loud speaker.

The arrangement of the instruments on the panel and base is shown. No wiring is shown in this diagram, as it would lead to confusion. All of the instruments are arranged so that the shortest leads possible can be used. A two-plate mica dielectric condenser was used by the author but this is not absolutely necessary. The tube socket is mounted directly in back of the "window" and the socket for the radio-frequency transformer is mounted back of this. The audio-frequency transformer is to the right of the R. F., and the crystal detector, which should preferably be of the fixed type, is placed between the two, directly underneath the B+ of the audio transformer. A .002 fixed condenser is mounted across the secondary, and one across the primary of the A. F. transformer. One is also connected directly to the positive B battery binding post. The grid battery, which must be used for the UV199 and C299 tubes, and is used to advantage with other tubes, is placed as close to the grid terminal of the tube as possible.

When wiring use bus wire if possible and make all connections as short as possible, soldering all contacts. Run wires at right angles to each other whenever you can, but do not attempt to make a good-looking job by running all the wires so as to make perfect right angle bends. The wiring of the set should be done for efficiency and not for looks. Right angle bends look

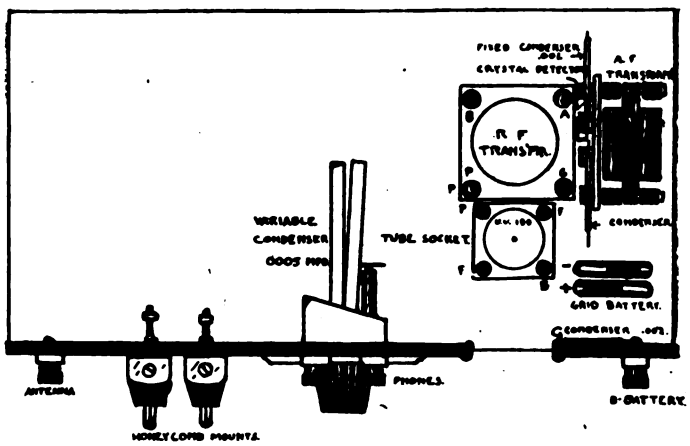

Fig. 2. Panel layout and arrangement of parts on base for efficient wiring. A hook type condenser is used for convenience and to save space.

good, but if the builder remembers that "a straight line is the shortest distance between two points," he will obtain better results.

Honeycomb coils are used in place of the conventional variocoupler. There is no deadend loss to these coils and they are simpler and easier to operate. One 35 turn, a 50 turn and a 75 turn coil are all that are required. Change these about until the best results are obtained.

The writer used a UV199 tube in this set and 112 volts on the plate, although better results could probably be obtained with a 201A or 301A tube with 150 volts on the plate. In most hook-ups given no

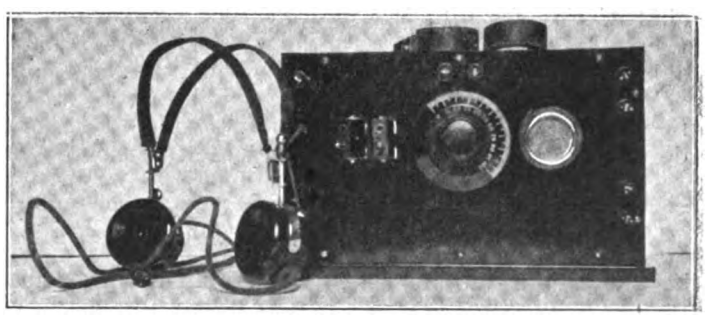

Fig. 3. Photograph of completed set, showing compact size and neat arrangement.

grid battery is designated. With the UV199, however, this is necessary for the best results.

No filament rheostat was used, as this simplifies the control, and as a rheostat is unnecessary with the hard tubes employed.

To tune, simply light the filament, tune the condenser and vary the distance between the two coils until the

Increase Use of Radio for Fog Signals

By Carl H. Butman

WASHINGTON, D. C.—Radio, within the next few years, will play an increasingly important part in the work of protecting those who go down to the sea in ships from the mishaps which have made life on the ocean wave more of a peril than a pleasure, according to George R. Putnam, Commissioner of Lighthouses.

Commissioner Putnam, as a result of his experience with radio in the Lighthouse Service, is an enthusiastic supporter of this means of communication, and expressed his opinions strongly at the recent International Congress of Navigation in London. At that time he asserted the belief that radio for signals was destined to become one of the prime factors in life saving work, and, since his return to Washington, has plunged into plans for extending the use of radio in the Lighthouse Service.

Although not the first country to install radio fog signals—France having done so several years before we took the matter up—the United States today leads the world in the number and efficiency of such signals, and our methods are being studied abroad in those countries where the subject is under discussion. Our radio fog signals are all sent out on a 1,000-meter wave length. Those of France were sent out on a very low wave length and were lacking in efficiency, and the French Government now is remodeling all sets so as to use the internationally-adopted wave length of 1,000 meters.

Radio fog signals, as their name implies, are sent out in foggy weather to warn mariners that they are near to dangerous coasts. They have an all-weather range of some 30 miles, but this range can be extended, if greater distance is deemed desirable. The sets are automatic, needing only to be started, and are cared for by light-keepers and others, no special radio knowledge being required.

The apparatus now used is actuated by spark sets, but the service is soon to install the first of the tube sets which will eventually supersede all spark apparatus. The conversion from spark to tube is being made in order that a sharper signal be sent out, that interference between nearby fog signals may be eliminated and in order that the apparatus may be used for other purposes than fog signals.

A plan is now under consideration of using these fog signals at all times, regardless of weather conditions, that vessels may use them for location purposes. There has recently been established on the Pacific Coast a new southbound route for coastwise traffic which is many miles out of sight of land, and it has been suggested that the fog signals along the route be sounded constantly that they may be used by vessels equipped with direction finding apparatus, for determining location.

Another scheme under consideration by Commissioner Putnam is that of sending the fog signals upon request of any vessel desirous of determining its location, the request to be transmitted by radio to the nearest receiving station. At present, the radio for signals in the vicinity of New York send for two 30-minute periods each day, one in the morning, the other in the afternoon, and many vessels take advantage of the opportunity to test out their direction finders.

"Radio for signals gives promise, for the first time, of placing at the disposal of navigators beacons for use in fog comparable to lights in their dependability and the possibility of affording accurate bearings, superior to lights in their range and usefulness under all weather conditions," declares Commisisoner Putnam. And, with that idea always in view, the Lighthouse Service is devoting much time and thought to the greater use of radio, the only new aid to navigation developed for a number of years.

Short and Snappy

MANY are the amateurs who like to "CQ." Of course this is the easiest manner of attracting attention if you own a CW outfit; but the international regulation specifically states that a call is to be sent three times followed by "de" designating the abbreviation form and then sign your own call three times. If you do not get an answer within a reasonable length of time repeat the performance.

Why in the name of all that is fair and good under the sun will nine out of ten amateurs C Q a baker's dozen, sign a couple of dozen and then without even stopping repeat the performance over again? One amateur was heard on 200 flat with a note like a humming bird at close quarters (sweet was no name for it) actually "CQ" 18 times by actual count, sign six and then repeat the performance. Supposing some other fellow wanted to get "through" to him? Do you expect he is going to patiently wait until he gets all through with his "code practice" until he calls him? Decidedly not. He will take his receiver elsewhere and talk to a rational body who does not have the idea that everybody must like to listen to his "fist" and beautiful "note" on a 20 watt input. Go to it fellows, but for the Old Man's sake, be sane!

(*Concluded from preceding page*)

best results are obtained. When the set is first made, you will have to find the proper value for the grid battery. This will vary between 3 and 15 volts, according to the tube and the plate voltage used.

The action of the set is as follows: When it is tuned, the radio-frequency oscillations are impressed on the grid of the tube. As the secondary of the A. F. transformer is in the grid-filament circuit, it is shunted by a fixed condenser. The tube amplifies the oscillations and relays them to the circuit which consists of the plate, primary of the R. F. transformer, condenser which is shunted around the phones and B battery, and the filament. The induced oscillations in the secondary of the R. F. transformer are rectified by the crystal, and sent into the primary of the A. F. transformer. They are stepped up to a higher voltage here and sent through the circuit which consists of the secondary of the A. F. transformer, grid and filament, this time at an audio-frequency. The tube again amplifies and relays the signals to the plate circuit. They flow through the primary of the R. F. transformer, and as they are now of an audio-frequency, they will flow through the phones instead of through the condenser.

This explanation shows how one tube in this circuit is as good as three in a plain circuit. If care is used in the selection of good parts and these directions are closely followed, no trouble will be encountered.

Increasing the Efficiency of the Receiving Set

By Byrt C. Caldwell

THIS article is written for the great majority of the radio public who own single circuit regenerative sets, or sets that regenerate by means of capacity feed-back, instead of by the more flexible inductive feed-back which is employed in the three circuit sets.

The amateurs (not the broadcast fans) long ago proved that the three circuit set was by far the better set of the two for both sensitivity, volume and selectivity. However, the idea is held by most broadcast fans, that the three circuit set is best only for its

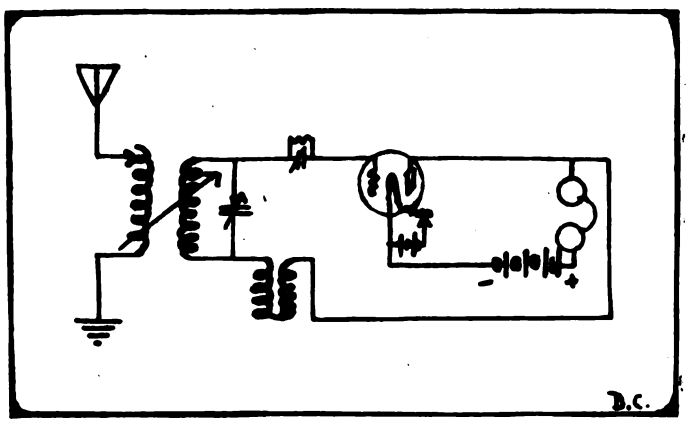

Fig. 1. Hook-up showing Caldwell's method of increasing the efficiency of the receiving set.

selectivity, and that the single circuit set excels when volume is desired. The amateurs are right. The reason that the fans have gained this impression is that they have seldom taken the time, and have seldom gained the necessary experience, to be able to tune the three circuit set for maximum results. I believe that any amateur will corroborate this statement.

The reason that maximum results cannot be obtained with these simplified circuits is that little control is had over the amount of regeneration obtained.

The writer has designed a set, or an improvement which can be added to any set, which increases the selectivity and greatly improves the results obtained, often doubling the volume of the signals. This addition puts the regeneration under control and in this way greatly improves results.

In constructing the set this improvement can be built right in. However, if the set is already made, it can easily be added. Briefly, the improvement consists of two honeycomb coils, connected in series in the plate-grid circuit. Room may easily be found for the coils over the variocoupler, or some place else on that side of the panel. Two 50 turn or two 75's will do, or if you happen to have a set of them, you can try different combinations until the best results are had. Connect them in series as shown. Be sure that the conections of one of the coils has not been reversed. Regeneration is controlled by varying the distance between them. If room can be found on the panel, a variometer may be used in place of the honeycomb coils. This would certainly be more convenient to operate. As to which would give the best results, I could not say, as I have not tried the variometer. I believe that the variometer would be more satisfactory.

The coils may be either back or front mounted. The diagram illustrates the arrangement of the instruments used in the hook-up shown.

The hook-up indicates how the coils are inserted in a circuit of this type. If your hook-up is of a different kind, you can easily place the coils in their proper positions by referring to the hook-up given. Place them in the plate-grid circuit.

Try this out. You will be surprised at the great

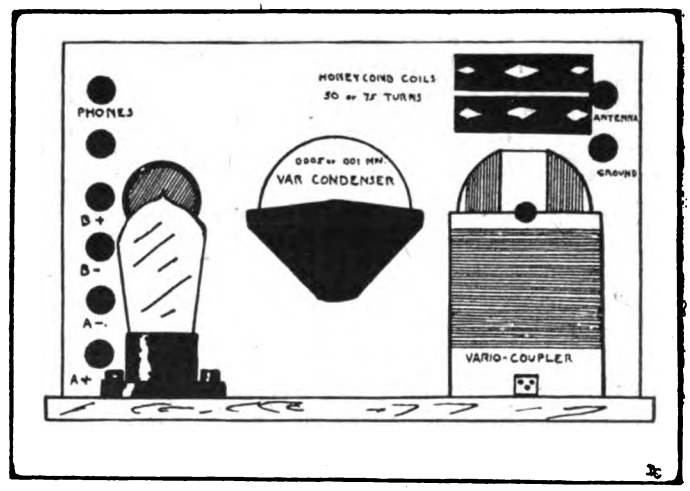

Fig. 2. Caldwell's suggested panel layout for increasing the efficiency of the receiving set.

improvement which results and the ease with which you can tune out some of the stations which formerly came in together.

Conserve the Current!

IF you were to measure the current that actually travels through the primary circuit of the radio receiver you would understand why it is that most receivers of the home-made type do not function well when it comes to distance. The actual current is so infinitely small that it is almost negligible, and when that same current has to actuate the delicate phones and other apparatus through a circuit that is full of high resistance joints (a soldered joint can be high resistance if it not done properly) you will probably understand why your set does not function as well as Jimmie Jones' even though you use better apparatus. He has his well soldered (not sloppily and without excess flux) and conserves the current. Think that over in your spare moments and then examine your set the next time you are hunting for that elusive distant station that just murmurs faintly in your phones, and which is plainly audible in Jim's.

By broadcasting revues of this sort from WJY, stars like Kin Carroll, Art Conrad, Harry Hanbury, Frank Taylor, Raymond Ghee and many other scintillating Broadway favorites are able to reach many hundreds of thousnds of interested radio listeners.

(C. Kadel and Herbert)

Dolores Cassinelli, noted woman fencer and instructor, taking a few moments' rest after a strenuous fencing lesson. Miss Cassinelli is a great believer in strenuous sports and a constant supporter of radio. She has a complete receiver in her room at the Hotel Majestic, New York City, as is shown, and takes great delight in tuning in on those distant stations.

American and Canadian radio fans who have listened in to CKAC, the broadcasting station of La Presse, Montreal, have had a treat during the past few weeks, thanks to the co-operation of the White Star Line. Each Thursday night a special program was arranged by one of the White Star ships that was in port and the music was broadcast through this station. The illustration shows the quintette of the S. S. "Doric," the largest ship to enter Montreal harbor. Left to right, they are Harold Cowgill, Ernest Jowitt, Arthur Ransley, Sam Wooley, Edward Cappi. They have introduced several of the latest fox trots and waltzes through the medium of radio.

Paul Whiteman's S.S. "Leviath an" Jaz
From New York

THE broadcasting by Station WJZ of Paul Whiteman's S. S. "Leviathan" Jazz Orchestra from the dock at the foot of West 46th Street, New York City, upon the return of Paul Whiteman himself from his successful trip to London, was an innovation never before attempted in broadcasting. The cheers of the crowds that recognized "Our Paul" and the strains of his famous "Leviathan" orchestra was something that, to say the least, was most novel.

The left hand illustration below shows the S. S. "Leviathan" orchestra on the dock before the microphone, preparing to broadcast one of their selections. The right hand illustration shows the "pick-up" and amplifying panels used to switch the microphone on and amplify the tiny impulses preparatory to sending them over l broadcast.

(C. Kadel and Herbert)

Here is a hint to mothers who have trouble in putting baby to sleep when out in the park. Take your De Forest set along and you won't be bothered by rocking him to sleep, and at the same time it will amuse you and keep you from feeding too many peanuts to the squirrels.

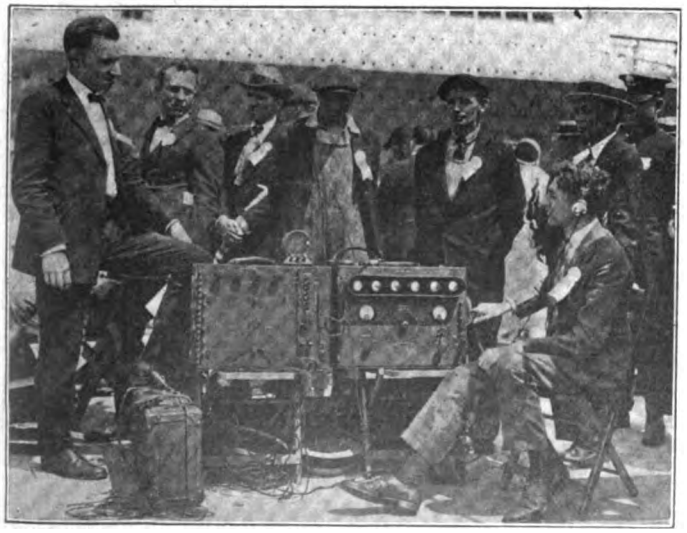
an" Jazz Orchestra Broadcasts York Pier

them over land lines to be further amplified and then broadcast.

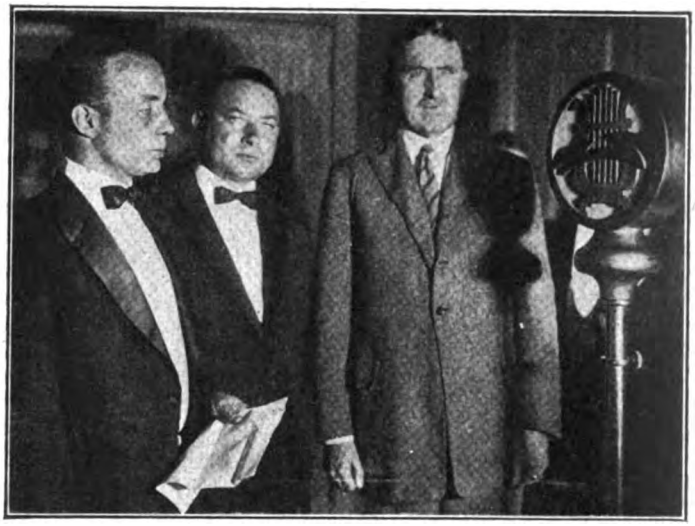
The recent arrival of the famous leader of America's most famed institution of musicians created quite a furore in broadcasting circles, and there is no doubt that every listener wishes that Paul Whiteman had a chance to arrive about three times a week.

On the evening following his arrival, the fans were able by means of radio to be present at a complimentary dinner tendered to him and to hear the specches and music. Well, there is little happens these days that the hundreds of thousands of listeners miss.

Of note to radio fans will be the fact that the power speech amplifier is using six UV201A tubes instead of the regular five watt tubes that are most usually incorporated in the apparatus.

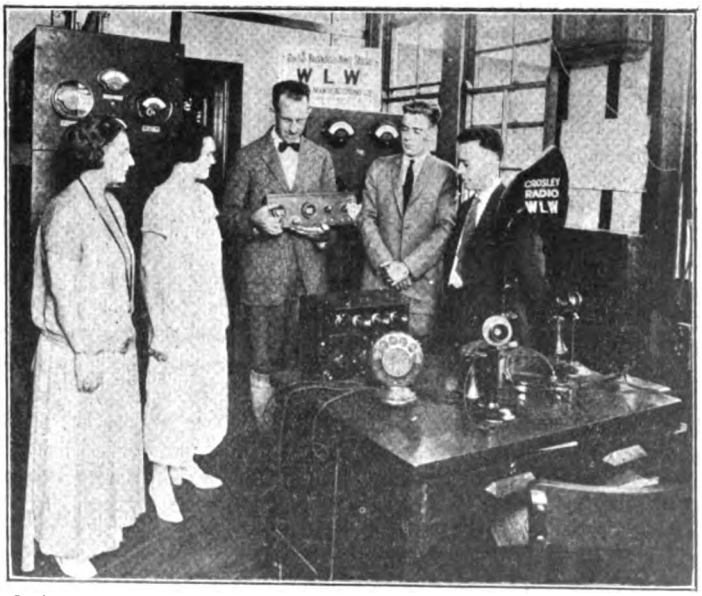


Leon Abrams, president of the Radio Chain Stores Co., of Trenton, N. J., being entertained while watching the bathers in the Delaware River by means of his portable loop receiver. This is a tip for the canoists. Take your portable set along with you instead of your "uke" and you can have variety—everything from a lecture on the evils of the drug habit to a cornet solo played by a member of the Police Band. This is the spice of life, these days.



(C. Underwood and Underwood)

Theodore Roosevelt, Jr., Assistant Secretary of the Navy; Major General Frank L. Hines, Deputy Chief of Staff, U. S. Army, and David Sarnoff, Vice-President and General Manager of the Radio Corporation of America, officiating at the opening of the new station WRC, Washington, D. C. Theodore Roosevelt, Jr., delivering the commemoration speech before the microphone of the new station.



Radio wedding candidates inspect broadcasting station WLW from which the ceremony will be broadcast. Mr. Powell Crosley, Jr., Chairman of the Radio Committee of the Cincinnati Fall Festival, explaining the working of one of the presents that are to be given to the principals in the forthcoming weddings. The ceremonies will be broadcast on September 4 from the Music Hall, Cincinnati.

Report on Fading

HARTFORD, Conn.—Fading shows no partiality to radio fans since all listeners have noticed that it interferes appreciably with the reception of broadcast programs. Fading is the variation in reception intensity caused by atmospheric conditions beyond control of the listener and cannot be associated in any way with the type and construction of receiving apparatus in use at the time.

A program may be coming in with such strength that it can be heard throughout an ordinary room when suddenly the volume of sound will diminish until it is scarcely audible with the receivers held close to the listener's ears. Observations of this condition have been completed by the U. S. Bureau of Standards in conjunction with the American Radio Relay League. A brief summary from the report to appear in the September issue of "QST" follows:

"Observations to date indicate that the fading is greatest for waves within a certain range of wave lengths, and is less for either longer or shorter waves. Fading is more pronounced at wave lengths in the neighborhood of 250 meters than at longer wave lengths. Transmission experiments using 100 meter waves indicate less severe fading than on 250 meters.

"It is easier for a large mass of something to somewhat obstruct a 200-meter wave than a 2,000-meter wave.

"A preliminary statistical study of the transmission range of certain broadcasting stations, which has been made since the work described here was done, indicates that at a distance of the order of 150 miles from the transmitting station a noticeable decrease is observed in the signal intensity, which increases again for greater distances.

"The distance at which this occurs varies with the wave length, which suggests that its explanation is associated with the variation of ground absorption with wave length."

New Stations Licensed

FOUR new radio broadcasting stations were given licenses and six stations were transferred from Class C to Class A during the week of August 13, the Radio Division of the Department of Commerce reports. Of the new stations, only one was in the eastern section of the country.

"Use Radio Sets in Balloon Races"—Olmstead

REPORTING officially to the Chief of the Army Air Service on the use of radio in balloon races, Lieut. R. S. Olmstead, winner of the recent race says in part:

The S-6 balloon radio installation complete with antenna and counterpoise weighed around thirty pounds, representing roughly one bag of sand ballast. Both Lieut. Shoptaw and myself agreed that it was worth several times its weight in sand. It should always be remembered, furthermore, that the set could be used as ballast quite efficiently by the simple process of dissembly.

Immediately upon taking off we dropped our antenna and (copper screen) ground and wired up to receive. The results were uniformly good from the first. Musical program after musical program with great clearness came in, and incidentally the Dempsey-Gibbons fight returns came from Detroit by rounds. There seemed always to be music in the air, and to anyone who has experienced the monotony, when everything is going well, of the hours of darkness in a balloon race flight, the value of such restful relief therefrom is very evident. There should always be two head-sets provided to a basket; we had but one. They do not interfere in the least with the work of the pilots, and the tendency is to wear them at all times.

From Detroit, Chicago and Schenectady, particularly from Schenectady, we received quite definitely the weather reports consisting of general flying conditions, wind directions and velocities, cloud conditions, and of great importance, the presures recorded at various important cities. This information was quite conclusive in influencing our tactics to obtain a suitable direction of flight in order to obtain maximum endurance and distance. A feature which should be added and which we keenly felt the need of for several hours while out of sight of any land marks over Lake Erie is a direction finding attachment. A loop hung above the load ring with compass attached thereto, it is believed, would solve this problem.

A point of vital importance in a race was the advice received by radio of the location of our various competitors from time to time. At the time of landing we knew that all but three of our competitors had been accounted for, and we were quite certain that we were in one of the three winning positions and eligible to go to Belgium. Had we not had this information, we might have tried to cross Lake Ontario without sufficient ballast, and failing in the attempt, would have disqualified ourselves.

My recommendations are that a radio set should be installed in every racing balloon, directional attachment should be added and two head-sets should always be provided.

Latest Radio Patents

Carrier Radiotelephone System

No. 1,458,949: Patented June 19, 1923. Patentee: H. W. Nichols, Maplewood, N. J.

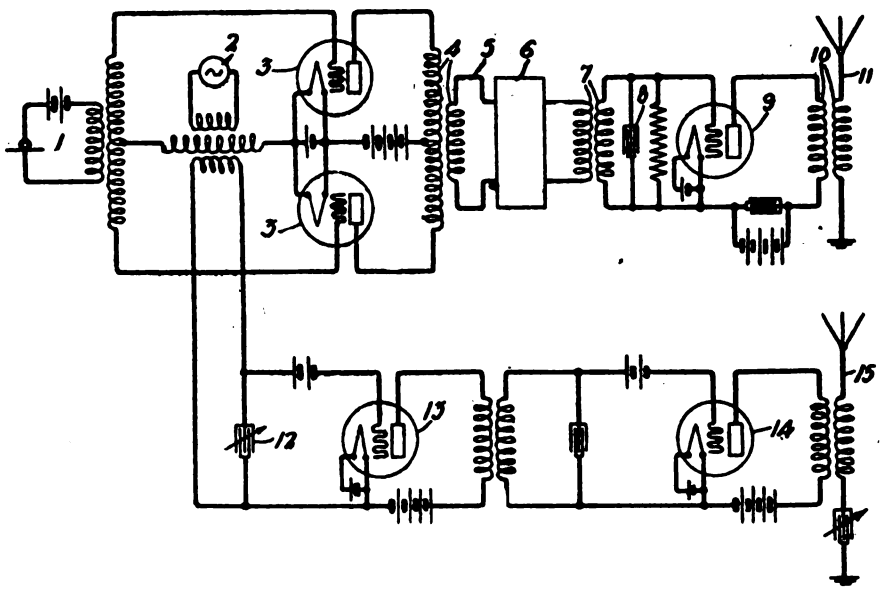
This invention relates to a method of and means for transmitting signals, and more particularly to carrier telephone systems.

It has been proposed in signal transmission by modulated carrier waves to prevent the transmission of the unmodulated carrier wave component, while providing for the efficient transmission of the modulated carrier wave component, as described in the Journal of the A. I. E. E. Vol. XL. No. 4, page 314, April, 1921. It has also been proposed in a carrier system, to transmit a signal modulated wave i. e. the modulated carrier and two side band components and an unmodulated wave of frequency different from that of the carrier wave. At the receiving station the signal modulated and unmodulated waves are combined to produce a signal modulated wave of intermediate frequency which is then selected and again detected to give the signaling current.

The present invention has certain advantages over each of these systems in that it does not require a synchronously operating source of local oscillations at the receiving station, as in the first system, or the additional detector, etc., as in the second system, to effect detection or demodulation of the incoming signal waves, whereby speech currents may be supplied to the receiver.

The present invention is directed to a system in which all the advantages inherent in the two systems briefly described above may be utilized and consequently a much greater economy of power and apparatus may be secured. According to this invention a carrier wave is modulated in accordance with speech frequency currents, the unmodulated carrier component and one side band are suppressed, the remaining side band of the pure modulated wave and a selected amount of unmodulated energy from the carrier source are transmitted independently and more efficiently to a distant cooperating receiving station where they are combined.

The primary object of this invention is to provide a carrier system which is both efficient and economical. Another object is to provide means whereby a pure modulated wave and energy of the fundamental carrier frequency may be transmitted from a signal station.



Method of producing a pure modulated wave whereby the unmodulated carrier component and side band are surpressed.

Electron Emitting Cathode

No. 1,459,466: Patented June 19, 1923. Patentee: C D. Hocker, East Orange, N. J.

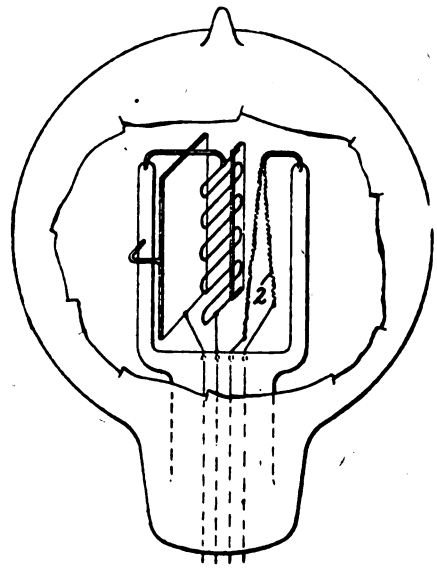
This invention relates to electron emitting cathodes, and the process of making the same, and has for an object to improve the characteristics of such cathodes in any one or more of the following particulars:

A.—To make the thermionically active coating adhere more firmly to the electrode or filament by mechanically binding the active coating materials to the filament.

B.—To increase the electron emission at any given temperature.

C.—To lengthen the life of the filament at any given temperature.

This is accomplished by adding another substance such as a noble metal to the coating before it is applied. By noble metal is included compounds of a noble metal from which the noble metal may be produced by heating a compound thereof; for instance, gold, silver and platinum may be produced by heating gold oxide, silver oxide and ammonium chloro-platinate, respectively. Among the noble metals may be mentioned silver, gold and platinum, and the presence of one of these metals in the filament coating has been found to give the desired result. Whether the noble metal will serve to mechanically bind the coating to the filament, whether it increases the electron emission or length of life, of any combination of these, depends upon the noble metal used as well as upon the particular thermionically active substance or substances of which the coat is composed. The particular substance used in the coat, and the properties of the filament that are thereby improved will be later described.



Details of a vacuum tube of the triode type which allows treatment whereby added electrance emission is possible.

The use of a material in the coating which serves to mechanically bind the coat to the filament has two distinct advantages: First, it makes it possible to apply any coating in an adherent form; second, it permits the application of coats composed of a mixture of substances of definite proportions—a definiteness which cannot be insured when these substances have to be alternately applied in layers as previous filaments have been made.

* * *

Electric Condenser

No. Reissue 15642: Patented July 3, 1923. Patentees: C. F. Smith and W. H. Smith, Brooklyn, N. Y.

Our invention relates to electric condensers and has for its object to provide an improved simple and efficient condenser of this character, and also an improved method for the easy and expeditious making of such condensers. Condensers of our improved type are intended primarily for use in wireless telegraphy or telephony but they are also adapted for other uses.

A satisfactory embodiment of a condenser made according to our invention is shown in the accompanying drawing. The condenser there illustrated comprises units any number of which may be assembled readily to form a condenser of the desired capacity. Each of the units shown comprises a base or body portion which gives the unit the requisite strength or stiffness; a flexible dielectric, preferably paper impregnated with insulating material, such as wax; and sheets of metal foil preferably non-resilient metal, such as lead or "tin foil," though other metal foils may be used; such dielectric and metal foils being folded or wrapped together.

Answers to Readers of Radio World

I have constructed the circuit shown on page 8 of RADIO WORLD, *April 7, and find that while local stations come in strong, I cannot get any distance. Could I apply the super-regenerative principle to this receiver in order to get distance?—James E. Stevens, 1734 K Street, N. W., Washington, D. C.*

You should not expect to do any distance work in the summer months. The fact that you receive local stations strong proves that the circuit will bring in distance in the cooler months. Even the circuits employing three and more tubes are hampered as to distance in the summer. Be satisfied that you have a very good circuit and do not bother with super circuits. They create lots of interference due to re-radiation of oscillations and are hard to tune. Excellent work has been done with the three circuit set you mention—in the cooler months. During the summer you should be satisfied to receive strictly local work, with probably a medium distance station on a cool evening or very early in the morning.

* * *

I have constructed the three-circuit type set using two variometers (moulded) and variocoupler. It works fine except for a high pitched whistle which I have brought to a medium by adjusting the grid leak, but still it is loud enough to be extremely bothersome when trying to listen to any programs. I can stop it temporarily by touching the shafting of the grid variometer and the ground post. How can I stop the whistle without dong this? Reducing the filament current does not help any as it squeals whether the filament is low or high.—Henry Ensminger, Pulaski, Ia.

Your trouble is probably due to the fact that your variometers and coupler are crowded together too closely, and therefore you are getting coupling from your grid and plate circuits. Space them and ground one side of the filament circuit, being careful that you do not short any part of your circuit. This should stop the squeal.

* * *

My neighbor and myself both have single circuit receivers, both designed and built the same, using the circuit described as the Colpitts oscillator. Neither of us can get any satisfactory results when we are both on as when one is tuned in it produces howls and screeches in the other. How can this howl be stopped?—J. L. Barney, Kelly Street, Bronx, N. Y.

There is no method of curing the howls caused by re-radiation on nearby single circuit sets. As long as both sets are in operation at the same time and listening to the same station, or on the same wave length, you will both be bothered with this howl. The particular type of set you mention is a very violent producer of oscillations and in receiving it really acts as a miniature transmitter, creating a carrier wave of its own, which is what you both notice so much.

* * *

I have four variometers, one 23 plate condenser and one 43 plate condenser, honeycomb coils 35, 50 and 75. Should I have a variocoupler? If so what make should I use? Is it possible to use R. F. ahead of the first tube in the Flewelling? Is this circuit superior to the super that uses D. L. 1250 and 1500 honeycomb coils? Is the Turnbull circuit with one stage of amplification superior to Flewelling and one stage of audio-frequency?—C. W. Fisher, P. O. Box 476, Souris, Manitoba, Canada.

You do not state in what circuit you want to use all the apparatus. There are several good makes of coupler on the market. If they bear a standard and well known trademark they are safe. It is not possible to incorporate radio-frequency with the receiver you mention, as the oscillations generated by the "super" action would render the circuit impossible to manipulate. Sufficiently loud signals should be obtained with this circuit to satisfy, but it is not as loud as those received on an Armstrong super-regenerator when properly operated and constructed. Turnbull has written several articles. You do not mention which one you refer to, so we cannot compare them.

* * *

Will you kindly check the enclosed hookup and let me know if it is the same as that used by Dick Roberts? If not, kindly correct it.—Alfred L. Megill, 761 Atlantic Ave., Brooklyn, N. Y.

Your circuit is identical with the one used by Dick Roberts. The circuit as supplied by the writer mentioned appeared in RADIO WORLD, August 18.

* * *

Can I use the variocoupler described by Arthur S. Gordon in RADIO WORLD, *March 3, in the improved Turnbull receiver, described in* RADIO WORLD, *July 14? Can this set be used with outside antenna without changes?—W. H. Morelourn, Thomaston, Conn.*

This set is designed for use with a loop, and if you desire the same circuit designed for antenna and ground, see article by the same author in RADIO WORLD, May 19. You can use the coupler mentioned in these circuits if it is carefully constructed.

* * *

Kindly advise me of a good circuit to use for the reception of distant signals. I am fairly well versed in radio, but as yet have only constructed the Rheinartz. Can you furnish panel layouts? Do you advise the Zenith circuit?—Henry Bergstedt, 6607 S. State Street, Chicago, Ill.

It is a very difficult matter to prescribe any particular circuit for the purpose you mention. Unless you wish to use more than two tubes, the Rheinartz is about as good as any. We do not furnish panel layouts. We cannot at the present time publish the circuit you mention.

* * *

In the article by D. S. Brown what is meant by "basket weave coupler?" He recommends exactly 63 1-3 turns on the rotor. Is it absolutely necessary to have that many? --Karl Dunlap, Kinmundy, Ill.

The basket weave coupler is made with small round uprights placed in the form of a circle instead of a tube. The wire is woven in and out of these. This lessens the distributed capacity. The mention of 63 1-3 turns was made as a little joke instead of a correct technical description. Wind it full of wire—whether there are 62 or 65 or 70 turns will not matter very much.

* * *

I have a two stage amplifier which worked fine last winter on 90 volts, but when the B batteries fell to 60 it would not work on the second step. After rewiring the amplifier, it does not work on 90 volts, but will on 45, and the second step is no louder than the first. My tubes are UV201 and have seen six months of good service and both work well as detectors with but 24 volts on the plate. How can I remedy my trouble? —Gene Ullemeyer, 1511 9th Ave., Rock Island, Ill.

Make sure that one side of your secondary amplifier transformer lead goes to the negative side of the A battery. Test out your transformer. There is a possibility that it is burnt out and you are getting return through some induction in the lines. This has been found to happen very often after months of operation, when the second stage suddenly lays down. Make sure of your connections before you get discouraged. Examine the nips of your tubes to see that they are all making perfect connection with the lugs on the socket. The little solder tip sometimes falls off, or wears off, and does not make good connection. See that it is not corroded and therefore making bad contact. Polish them by means of a very light rubbing with emery cloth.

* * *

In RADIO WORLD, *August 4, you published an article by A. D. Turnbull. Is this circuit adaptable to a six volt tube operated by a storage battery? If so, what are the constants of the circuit with especial reference as to whether or not the tube is a detector or amplifier, the voltage of the B battery, size of grid leak? Is a vernier rheostat essential? How is panel shielding most effectively and cheaply accomplished?—Harold W. Crockett, 2624 Channing Way, Berkeley, California.*

This circuit is adaptable to a 6 volt tube simply by using a suitable socket instead of the dry cell socket. The constants remain the same in all cases, with the possible exception of the grid leak, which should be variable in order to determine what is the best value for the particular tube you are using. A vernier rheostat is not absolutely essential, but it is extremely helpful. Shielding a panel is best accomplished after the panel is completely drilled. Lightly sandpaper the rear surface, rotating the paper in circles instead of straight. Give it a good coat of thin orange shellac, and let it dry partially until it is very sticky. Then cover the back of the panel with tin foil, pressing it on firmly and smoothly by means of a roller. Allow to dry 24 hours in a cool place, and then with a sharp knife cut away circles in the spots where your holes are drilled. When the set is constructed, ground the shielding to the ground post of the set.

* * *

I am learning the code by using a Ford spark coil connected across the antenna and ground by means of a spark gap. A 6 volt storage battery is used to supply current for the operation. I wish to know if this is transmitting. Could I cause any disturbance to local stations by so doing? I do not have a license. Where can I get information on the necessary knowledge to enable me to obtain a license?—Kent Deckard, P. O. Box 3, Rusk, Texas.

You are transmitting. Furthermore, you are using an untuned transmitter which is capable of radiating a very broad wave and creating a great deal of disturbance. The best manner of learning the code is by means of a key, dry cell and buzzer. It does not have to be connected to the antenna. If you continue you will get in trouble with the government, so stop it until you can obtain a license.

In order to get an amateur license you must be able to send and receive at least 10 words per minute (five characters constitute a word, so 50 characters per minute is necessary). You must have a knowledge of the international radio laws pertaining to the secrecy of messages, the operation of a station during distress calls, the international abbreviations. You must also be able to draw diagrams of your receiver and proposed transmitter, and have a knowledge of the working of both. You must know your transmitting input and output and be able to answer questions on simple electricity. For further information write to the Department of Commerce, Radio Division, Washington, D. C. The radio inspector in your district is located at New Orleans, La. Apply to him for information and stop transmitting until you obtain a license.

* * *

Can I add a one or two stage amplifier to the dry cell circuit of A. D. Turnbull, published in RADIO WORLD, *August 4?—Henry Conn, Boonton, N. J.*

You can do this. A suitable circuit for your purpose appeared in RADIO WORLD, August 18, page 20.

Radio takes another step forward with these wonderful new Magnavox devices

THE new Magnavox models here shown extend and supplement the already famous Magnavox line of Reproducers and Power Amplifiers. There is a Magnavox for every receiving set.

New Magnavox Combination Set

A2-R Insures convenient and perfect Radio reproduction. Consists of Magnavox Reproducer with 14-inch horn and 2-stage Magnavox Power Amplifier, as illustrated $85.00

Magnavox Reproducers

R2 with 18-inch curvex horn in new acoustic finish . $60.00

R3 with 14-inch curvex horn in new acoustic finish . 35.00

M1 *new Magnavox Reproducer* requires no battery for the field, thus meeting requirements of dry battery receiving sets. With 14-inch curvex horn in new acoustic finish . . . 35.00

Magnavox Combination Sets

A1-R consisting of Magnavox R3 Reproducer with 14-in. horn and 1-stage Magnavox Power Amplifier . 59.00

A2-R consisting of Magnavox R3 Reproducer with 14-in. horn and 2-stage Magnavox Power Amplifier . 85.00

A1-M same as A1-R but with the new Magnavox Reproducer M1 . . . 59.00

A2-M same as A2-R but with the new Magnavox Reproducer M1 . . . $85.00

Magnavox Power Amplifiers

A1 meets the demand for a 1-stage Power Amplifier. Special finish metal case. 27.50

AC-2-C Magnavox 2-stage Power Amplifier with Bakelite panel in highly finished hardwood case . 55.00

AC-3-C Magnavox 3-stage Power Amplifier . . 75.00

Ask your dealer for a demonstration. Interesting booklet will be sent on request.

The Second Annual National Radio Week

Almost a year has passed since the inauguration last fall of RADIO WORLD'S suggestion of National Radio Week.

The intention of everybody this year is to make the Second Annual Radio Week more important in every way than the initial event.

This is not a one paper or a one man idea. It is altogether too big and too good for that. Everybody last year joined hands with everybody else, and the result was worth while.

Let's join together once more and do our utmost to make the Second Annual Radio Week bigger and better than ever.

Have you any ideas? Send them in.—Editor, RADIO WORLD.

Mayor Moore Strong for Municipal Radio

EDITOR, RADIO WORLD: A municipally owned and operated radio broadcasting station would appear to be a future requirement of every large city. It presents unlimited capacity for the apprehension of criminals, to warn the citizens in the event of conflagrations, disasters, and to inform residents of the latest schemes of sneak thieves, confidence men, and others who prey upon the public.

The radio of the future will unquestionally enter into official municipal activity, and will, no doubt, in a relatively short time take its place among all progressive discoveries and inventions in its service to the citizens.

Very truly yours,
J. HAMPTON MOORE,
Philadelphia. Mayor.

Information for RCA Dealers

PIERRE BOUCHERON, advertising and publicity manager of the Radio Corporation of America, is making a thorough tour of the Mid-West where he is visiting the leading RCA jobbers and dealers in an endeavor to secure a cross-section of opinions and views on the radio trade tendency in that territory. Mr. Boucheron is particularly interested, while on this trip, in conducting research in the Mid-West territory for the guidance of the Radio Corporation in its future relations with the trade.

The results of these observations he will incorporate in a free course to radio dealers, to be known as "How to Sell Radiolas." The object of the course will be to bring to their attention the three fundamental ideas behind successful retailing activities and to suggest applications of these fundamentals that will be useful to the dealer and jobber in selling Radiolas. These ideas will include advertising, demonstrating and service.

It is believed the radio trade will find this information highly valuable in the conduct of their work when the data is made available in handbook form.

The Way Sol Kahan Does It

Other Newsdealers Can Do the Same Thing

Sol Kahan keeps a prosperous news, stationery and cigar store at 305 North Avenue, New Rochelle, N. Y. He sells a great many RADIO WORLDS in the course of a month. We noticed recently that Mr. Kahan had two unsold copies of RADIO WORLD of August 11 on his stand. A few days later he was asked if these copies had been returned to the American News Company, and he replied, "No. I keep my back numbers of RADIO WORLD in stock and sell them out, sometimes quite a while after their dates. I find there is a good demand for back numbers. In this way I always sell out my full supply of RADIO WORLD."

Here is a tip worth following by other newsdealers.

Samuel W. Chapman, proprietor of The Electric Shop, Cortland, N. Y., has filed a petition, with liabilities of nearly $10,000 and assets of $3,950, with creditors principally in New York City.

Classical Jazz Via Radio

A NEW development in music that has been stirring up a great deal of talk lately, not only in musical circles, but with the general public, has taken place. The persons responsible for this latest innovation are Francis Loubet, musical director and bandmaster, and his manager, Max Brav, both very well known to the music world. According to a recent canvass of the radio broadcasting stations, the most popular music proved to be grand opera and typical American "jazz," and these gentlemen have hit upon the novel idea of combining both. In other words, we will now be able to listen to a potpourri from "Aida" or "Carmen," or one of Tschaikowsky's famous compositions arranged in "jazz" form, without in any manner detracting from the value of these masterpieces. This new idea is expected to prove a fitting form of musical entertainment for the most critical student as well as the modern dance enthusiast.

Radio Literature Wanted

Manufacturers of and dealers in radio apparatus and accessories are notified that literature and catalogues describing their products have been requested, through the Service Editor of RADIO WORLD, by the following:

Carey's Repair Shop, R. R. No. 3, Galveston, Indiana. (Dealer.)
H. H. Gardner, 63 Clark St., Malden, Mass.
Alva D. Kerr, Oakland, Maine.
Richard Bladel, 1522 Ninth Ave., Rock Island, Ill.
Leland Schermerhorn, Radio Operator, S. S. "Wm. T. Roberts," Marine P. O., Detroit, Mich. (Assembles receiving sets.)
Fred A. Mulligan, Rosser, Manitoba, Canada.

Radio Press Dinner and Get-together Jollification at the Hotel Pennsylvania

REPRESENTATIVES of radio and various other papers gathered at the Hotel Pennsylvania, New York City, on Wednesday evening, August 22, for the purpose of welcoming Benjamin J. Cohon into the radio fold. This event was planned by Philip Wolf and Harry Saunders, of Philip Wolf, Inc., advertising agents for Rova, and who brought together these representatives on the occasion of Mr. Cohon's joining the Rova concern. Mr. Cohon, who lives in Westwood, N. J., is a noted organizer, having for several years aided in the building up of the successful and far-reaching policy of the United Cigar Stores under the able leadership of Edward Wise. Mr. Cohon, who is now vice-president of the Rova Products Corporation, becomes so for the purpose of stabilizing radio merchandising activities in the metropolitan area.

Besides an excellent dinner, served more or less in accordance with the novel menu card reprinted herewith, there were several impromptu talks, including an interesting one by Mr. Cohon.

Frank Tinney, the noted comedian, was among those present. During his remarks Tinney said that one night after his wife had gone to bed he tried for DX, but that all he got was "Hell." Mrs. Tinney, who also was among those present, assisted in entertaining the guests in her clever way.

Mr. Tinney's remarks, as well as the addresses by the others who spoke, were broadcast by WJZ.

Those in attendance were: Mail, Stuart Rogers, F. F. Humphreys; Sun-Globe, E. L. Bragdon, F. C. Ehlert; Tribune, Jack Binns; Times, O. E. Dunlap, Jr.; Brooklyn Eagle, E. M. Applegit; Radio Dealer, L. A. Nixon, N. B. Zimmerman; Radio News, S. Gernsback, R. W. Demott; RADIO WORLD, F. S. Clark; Wireless Age, H. L. Welker; Radio Retailer, A. H. MacAttamanay; Radio Broadcast, A. H. Lynch; Radio Record, A. Borras; Phonograph Weekly, Sidney Davis, M. Kennedy; C. B. Popence, Broadcasting Director R. C. A.; Frank Tinney, the comedian; Frank H. Shevit, N. Y. American Tax Expert; B. J. Cohon, Vice-President Rova; Mrs. Frank Tinney; Mrs. Goldman, Rova; Philip Wolf, Harry Saunders, Philip Wolf, Inc., Adv. Agents for Rova; Henry Anchester, President Greeley-Madison; Sonny Brakas, Leo Fried, Rova; Ralph Rubenstein, Rova.

Advertising Vigilance Committee Rules Against Storage Battery Advertiser

THE Radio Dry Storage Battery Company, of Chicago, has advertised its "Radio Dry Storge Battery" as—

"OUR GUARANTEE. Each RADIO DRY STORAGE BATTERY carries with it a THREE-YEAR UNCONDITIONAL GUARANTEE, on adjustment basis."

The guarantee has been further described and referred to in the company's advertising as—

"EXIT REPAIR BILLS. Our strong GUARANTEE eliminates repair bills entirely, giving the consumer a new battery at once if anything goes wrong with his battery."

"Backed by an Iron-Clad Three-Year Written Guarantee."

"It is guaranteed under an unconditional three-year guarantee."

The above phraseology would lead a prospective purchaser, to believe that a battery procured from this manufacturer bore an unconditional guarantee for three years, and that should the battery require replacement or repair, within the period stated, he might expect same *free*.

The guarantee which the company actually gives is this: If the battery has been used for ninety days or less, it is replaced free of charge, but if it has been used for over ninety days, it is replaced only on payment of an "adjustment," computed at the rate of 2 cents per day. In reality, the battery is unconditionally guaranteed for ninety days; it is thereafter guaranteed on an adjustment or conditional basis, contingent upon the payment of a service charge. Adverised as an "unconditional guarantee" and as entirely eliminating repair bills, replacement under these conditions could occasion an expense of $10, $15, or even $20 or more.

In view of the discrepancies between the advertised guarantee and the guarantee really given, the National Vigilance Committee is of the opinion that this advertiser's copy is decidedly misleading, and cannot recommend it.—*Advertising Club News.*

Managers and Music Publishers Stop Fighting Radio—Now Utilize Its Advantages

RADIO is rapidly battering down many prejudices. It is not so long ago that theatrical managers and music publishers would have nothing to do with radio or at least they refused to join hands with it in any endeavor to entertain the public. RADIO WORLD announced recently that Marcus Loew had taken over the WHN station and installed it in his State Theatre Building on Times Square, New York City. Now along come the music publishers including E. C. Mills, head of the Music Publishers Protective Association, with a special event the chief items of which were broadcast by Station WJZ. In other words, managers, music publishers and others are taking the stand that so long as radio is too strong to fight they might just as well avail themselves of its advantages.

Paul Specht, orchestra leader, and the members of his band, who have just returned from a successful musical invasion of England, were tendered a reception and dinner by their friends in the musical profession at the National Vaudeville Artists Clubhouse, New York, last Monday evening. This is the best equipped and most beautiful theatrical clubhouse in the world.

Theatrical folk and others all over the country who were not able to be present listened in on radio and sent congratulatory telegrams saying that they approved of everything that was going on and wished to be there.

E. F. Albee, head of the B. F. Keith Circuit, sent a congratulatory letter to Mr. Specht and his men. C. E. Mills was master of ceremonies and Jack Bliss acted as toastmaster. Many prominent musicians, civic officials and members of the theatrical profession were present. Specht was given a diamond and pearl set of studs as a token of esteem.

National Association of Broadcasters Supplies Members with Music

L. BAMBERGER & COMPANY, Newark, N. J., owners and operators of Station WOR, have announced that they will appeal to the United States Supreme Court the decision handed down against them recently by Judge Lynch. As announced in RADIO WORLD last week, this was in the case of M. Witmark & Sons, music publishers of New York City, against the Bamberger firm for broadcasting copyrighted music. Judge Lynch decided that such use of the music violated the copyright law and he naturally expects to be sustained by the Supreme Court. As far as broadcasters are concerned they are confronted by the Judge Lynch decision, which plainly states in effect, that they cannot broadcast the music of the American Society of Composers, Authors and Publishers, without taking out a license.

Now, what have the broadcasters themselves done to meet this situation? A meeting was called at the Drake Hotel, Chicago, on April 25 and 26, 1923, which was attended by most of the prominent broadcasters in the United States, as noted in RADIO WORLD at the time. The general manager of the American Society of Composers, Authors and Publishers, came from New York and addressed the meeting. His proposals, however, made a decidedly unfavorable impression upon the men assembled, and it was therefore decided to form the National Association of Broadcasters. Counsel was retained. Paul B. Klugh took active charge of the affairs of the association, with the title of executive chairman. Offices were established in New York and plans were put into operation for placing the new organization upon a practical operating basis. A fund was provided adequate to meet all financial requirements for a period of years and a constitution and by-laws were adopted containing the following purposes:

To foster and promote the development of the art of radio broadcasting and the interests of those engaged in any business, profession or industry relating or pertaining to radio broadcasting; to reform abuses relative thereto; to secure freedom to its members from unjust and unlawful exactions; to procure uniformity, equity and certainty in customs and usages of trade and commerce relating thereto; to settle differences between the members, and to promote a more enlarged and friendly intercourse between members; to secure co-operative action in advancing the common welfare of its members and proper consideration and concentration of opinion upon questions relating thereto; to advocate the enactment of just and equitable laws pertaining to or affecting radio; to support every movement to advance the radio art, and to encourage and aid in the development of musical and literary genius, especially where such genius has not had proper recognition.

Among other activities, a Bureau on Music Release was established. It is headed by Raymond Walker, an experienced song writer and publisher, who has a corps of skilled and able assistants. This bureau has invited song writers and publishers to send their music to the executive offices through display advertising in periodicals read by song writers, announcements by members over the air and thousands of letters sent out. As a result several thousand musical compositions have been received of varying degrees of merit. These are all put through systematic tests—less than 10 per cent. have been found acceptable—but where a song bears evidence of becoming a so-called "hit" and has clean lyrics, it is released by the National Association of Broadcasters.

Since July 1, this music service has been going out to members of the national association. The music is of a great variety, and, in the opinion of many, of a better quality than that controlled by the American Society.

Members of the National Association of Broadcasters, therefore, are not worried about the Judge Lynch decision. They are not even interested in it, because they are receiving an ample supply of good music which permanently frees them from any demands similar to those so unjustly made by the avaracious American Society of Composers, Authors and Publishers.

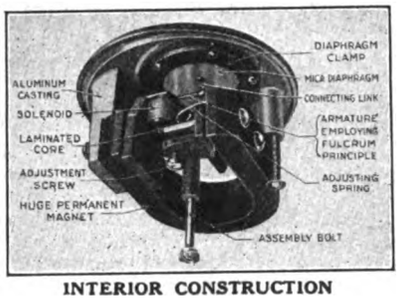
Aid for Canadian Radio

GOVERNMENT aid to the extent of $55,000 has been extended in Canada for the purpose of establishing radio stations at McMurray, at the end of the railroad in Northern Alberta; Fort Simpson, on the MacKenzie River; and Dawson, in the Yukon, according to reports just received at the Department of Commerce. The new stations will displace the land lines at present in use from McMurray northward, for which the Canadian Government has appropriated from $275,000 to $300,000 annually for the past 23 years.

THE TRINITY LOUD SPEAKER

TYPE "A1"
21" FIBER
HORN
$25.00

TYPE "B"
(For Phonographs)
$12.50



INTERIOR CONSTRUCTION

An ear phone is an ear phone no matter how fancy the horn that covers it may be, and, due to the delicate construction of an ear phone it is utterly incapable of giving true tone reproduction, especially, when relatively large currents are passed thru its coils, such as the output of a two-stage or power amplifier.

The Trinity Loud Speaker element embodies the well-proven and tested principles of the phonograph reproducer with the soundest principles of electromagnetic design best adapted for loud speaker operation. It is not an ear phone when placed on a head band and a loud speaker when covered with a horn. It is a sturdy loud-speaking element ALWAYS.

The Wireless Oracle Speaks

By Hirsch M. Kaplan

Irene Owens, who sang through station WOR, has a voice like a nightingale.

* * *

WDAR comes through at all hours these days. Your programs sure are the cat's pajamas. Keep it up!

* * *

Fine stuff, WAAM! You sure have some of the larger stations beaten.

* * *

See where "M. T. G." (the gentlemen who won't divulge his name) announcer at WHN, is copying your style, Roxy. Never mind though—you're still miles ahead of your closest competitor.

* * *

Edward Yap sure can "Say it with a ukulele."

* * *

Now that you've come under new ownership, WBS, let's hope that there will be an improvement in your station.

* * *

Say WHN, when you were over in Ridgewood, as our Dr. Coue would say, "Day by day in every way you were getting better and better." Now, in your new home, although your volume is good, your modulation is terrible. Too bad, as the programs you are offering leave a poor impression.

* * *

Mustn't forget our ever ready friend, Fred Bendell, sporting editor of the Newark "Sunday Ledger." Your talks, I can safely say, are enjoyed by all.

* * *

KDKA broke through with the 100 per cent. Westinghouse Band, which sure was the bee's knees.

* * *

WDT, you may be trying your darndest, but, as Rube Goldberg of the Evening Mail says, "It don't mean anything." We B. C. L.'s are from Missouri and we've got to be shown.

* * *

WSB came through with a 75 per cent. Radiowl Concert.

* * *

Gdubb, the sax player of the Lucky Strike Operators, certainly can blow some very peppy songs through his instrument.

* * *

Robert and Merrill Pollock are some jazz songsters. Did you hear them from WJZ the other night?

* * *

Have you ever tuned for a DX station just when the time signals are being transmitted by the various stations, then suddenly you stop on hearing sounds like that of a clock, thinking that you had station PWX of Cuba, only to listen patiently for the announcer and then hear him say, "This is station WHAS?"

* * *

Suppose you've all forgotten by this time that there ever was a station WJY? Well, just let me remind you that this station is still on the air every Sunday afternoon from 2.30 to 6.30.

* * *

Miss Leonia Adams sure is a "second best" to Alma Gluck. That's saying something!

* * *

The radio musical fans' delight—the New York Philharmonic Concert Orchestra and Franko Goldman Band. What say you, lovers of good music?

* * *

Dave Saperstein certainly can tickle the ivories and, as Roxy would say, "Bravo!"

* * *

Did you hear the reception given Paul Whiteman on his return from a London engagement? There were at least five orchestras and three popular male singers. They sure were some Jazz Boys. To put the finishing touches to the ceremonies Paul was crowned Jazz King.

* * *

If you didn't tune in WHAZ the other night and hear the nine-year-old Beatrice Gilbert tickle the ivories then you missed a treat. Another prodigy!

* * *

Suggest that Earl Dana do a few hours "mike" practice before he broadcasts again. Although an excellent literary critic, his style of delivery over the radio leaves much to be desired.

* * *

The First Baptist Church of Worcester, Mass., will be on the air shortly with "This is station WBAK, 252 meters."

* * *

When it comes to bedtime stories and such, there are few stations that can beat WIP's "Uncle Wip." Somehow or other he sounds convincing, and that's the quality which is lacking in most sandmen.

Army Radio Service Pays

THE army radio net, valued at approximately $500,000, made a return to the Government of over 10 per cent. during the past fiscal year, on paper. From June 30, 1922, to July 1, 1923, the traffic handled by the Signal Corps radio net would have cost the Government $66,375 at government rates, via commercial wires. The actual cost of these operations was $13,840, which shows a paper saving of $52,535. Actually official messages are handled without cost, and the few private and commercial messages handled, where other radio service is not available, is charged for at slightly over commercial rates, the money being turned over to the Treasury of the United States.

During the fiscal year ended July, 120,968 official messages were handled by the Army's Message Center in the Munitions Building in Washington, D. C.

In the army's radio net there are today thirteen main stations, 43 corps area stations and 12 air service or flying field stations, making 68 principal stations. In addition, there are auxiliary stations which bring the number to 112 radio stations.

LAUGH at Your LANDLORD

If he refuses to allow the construction of an aerial. The LEVIN "NO-AERIAL" RECEIVER solves the problem in an economical way. Just connect your Levin "No-Aerial" receiver to the water pipe or radiator and listen in. This receiver requires ONLY a ground connection for perfect reception. Send stamp for further information or $1.00 for plans and specifications, including full-size panel layouts and instructions.

RADIO EQUIPMENT COMPANY

727 W. 8th St. JUNCTION CITY, KANSAS

Sebring, Fla., heard Honolulu. A man writing from Nassau, British West Indies, says, "First of all on Friday night last June 29, 1923, I heard Honolulu." These records were made with a Crosley Model X. Thousands of letters have come to us unsolicited, telling of the wonderful performance of this instrument.

The new Model X-J, combining all the features of the Model X, with greater refinement of detail, is even better. It is a 4-tube set incorporating one stage of tuned radio frequency amplification, detector and two stages of audio frequency amplification with jack to plug in on three tubes for head phones, new Crosley multistat, universal rheostats for all makes of tubes, new condenser with molded plates, filament switch and other added features.

We believe the Crosley Model X-J to be the most efficient radio receiver ever offered to the public regardless of price. Write to-day for free catalog describing the Model X-J and other Crosley receivers and parts.

The Potentiometer Did the Trick

EDITOR, RADIO WORLD: I have noticed in several of your past issues that your writers have made particular note of potentiometers in the circuit. I recently constructed a two-stage radio-frequency set from a plan submitted by a local "radio expert." I have had rather indifferent success with it, as one night it would seem to work right and other nights it would not work satisfactorily at all.

I noted that most all the circuits in RADIO WORLD using radio-frequency amplification also used a potentiometer. I pondered over this for some time and finally installed one. It was a simple job, and not as hard as I had expected. I must say that I have improved my set by its use.

As an illustration, I used to get WLW just faintly readable at times, while at other times it was fairly strong. Since I have installed the potentiometer I have been able to bring in that station, as well as many others fine and without the tubes seeming to "jam."

I want to thank you for your advice in the matter, even though I am not a believer in "do-dads" in a receiver.

Hope anybody who has trouble in using radio-frequency amplification will be helped by my experience. I said that it was greatly improved. In thinking it over, I believe that an improvement value of 100 per cent. will not be an exaggeration.

Yours truly,
Ridgewood, N. Y. JAMES MORTON.

Bureau of Standards Reports on Amplification Measurements

MEASUREMENTS of voltage amplifications of audio-frequency amplifiers are discussed in Letter Circular 98, which has just been issued by the Bureau of Standards for free distribution. This circular gives the results of voltage amplification measurements made on 16 audio-frequency amplifiers which were on the market during 1921-22. All these amplifiers employed transformer coupling. Measurements were made over a frequency range of 400 to 2100 cycles per second. The amplifiers studied are referred to by arbitrary reference numbers rather than by a statement of the manufacturers' names and model number, the method followed being the same as that used in measuring the voltage amplification of amplifiers, the subject of Letter Circular 86.

It is believed that the examples given in this report will be of assistance to manufacturers in testing and describing their own products and will thus lead to their improvement.

Government Radio Directory Out Soon

LISTS of broadcasting, amateur, Government and ship and land commercial stations have been prepared and transmitted to the government printer for use in the forthcoming directory of stations, which will be available in about six weeks.

These lists are issued annually, giving all stations in service at the beginning of the fiscal year, on July 1. Two books are issued—one covering commercial, Government and broadcasting stations and the other amateur and special stations. Each station is listed twice, by name of owner and by call, and the lists are arranged by districts, in the case of amateur and special stations, and alphabetically in the case of all other stations.

Announcement will be made in these columns when the lists are ready for distribution.

Radio Equipment for a Philadelphia Hotel

NOT only has the Philadelphia public been bitten with the radio bug, but apparently the more prominent hotel and apartment house owners and engineers also have decided that radio benefits are to be a future added convenience to the comfort of their tenants.

The Pennsylvania Hotel, which is rapidly nearing completion at 39th and Chestnut streets, Philadelphia, contains upward of 600 rooms divided into 140 single rooms and baths and 160 suites ranging from two to six rooms and baths, each completely equipped with dining room and kitchenettes, making it the second largest hotel in Philadelphia and the second largest hotel of its type in the United States. It is to be equipped with one of the most modern and comprehensive radio systems in the world, to be installed by Durham & Company, Inc., radio engineers of Philadelphia, using Western Electric equipment throughout.

A special radio room has been built upon the roof, which will be equipped with a modern type receiving apparatus connected to powerful amplifiers distributing the received radio features from local and distant stations to the main dining room, the lobby, the lounge, smoking room, banquet hall, and grill, separately or to any of these locations simultaneously. The distributing apparatus consists of projectors, or as they are commonly known, "loud speakers," of special design made by the Western Electric Company, and giving a much better quality to the received energy than is present with the usual type of loud speaker.

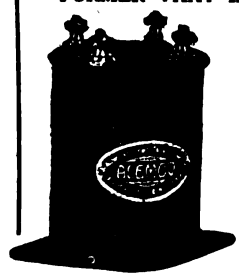
Another novel feature about this particular installation is the paging system that is to be inter-connected with the radio equipment for the halls and lobbies. For example, the telephone operator sitting at her switch board can, by plugging in a microphone, talk to any one or all of the output stations and make whatever announcements she may desire. In this manner the paging of the tenants and guests is accomplished and announcements of importance may be made to the diners or individuals in various parts of the hotel.

No longer will it be necessary for diners to sit at their tables after having eaten to enjoy the orchestra music, for microphones are to be placed near the orchestra and music sent along wires to the lobbies, and lounges, throughout the Pennsylvania Hotel. Also, the transmission of lectures or speeches from any one of these locations is to be re-transmitted to all gathering places in the hotel, thereby greatly increasing the audience present and distinctly adding to the speaker's appeal.

The tendency of the enterprising builder and engineer is very rapidly approaching the inclusion of the most modern devices of this kind in their building plans. The installation of a mammoth radio equipment of proper design is naturally a problem which would be different in each case and which must be solved by specialists in this newer type of engineering. The term "radio engineering" is hardly an adequate term to cover the problems that are involved, and fortunately the past experience of our telephone engineers in the amplification of sound has very materially assisted this new art.

RUSONITE
CRYSTAL RECTIFIER
(Patent Pending)
THE PERFECT SYNTHETIC CRYSTAL DETECTOR—SENSITIVE OVER ENTIRE SURFACE
No Hunting for "Spots." Loud and Clear. Endorsed by Thousands of Satisfied Users.
Sensitiveness Guaranteed — Price Mounted 50c
14 K. Gold Supersensitive RUSONITE CATWHISKER. Price 25c
Permanent. Will not Oxidize.
RUSONITE REFLEX CRYSTAL
Manufactured Expressly for Reflex Circuits. Will Stand Up Under Heavy Plate Voltage.
Guaranteed — Price Mounted $1.00
Order from your dealer or direct from RUSONITE PRODUCTS CORP.
15 Park Row New York, N. Y.

AN AUDIO FREQUENCY TRANSFORMER THAT IS WORTH WHILE
ALEMCO



Specially designed to produce superior results with any standard tube. Produces maximum amplification without distortion or howling. Moisture, hard knocks and abuse will not affect its efficiency.
Windings completely surrounded with laminated iron and sealed in a non-inductive bakelite housing eliminating leakage. Adaptable to any stage of amplification.
Ratio 4 to 1
The Alemco Coil also gives equal or better results on the first stage than transformers on the market wound as high as 9 or 10 to 1.
Will stand any voltage.
Price, $5.50 Postpaid
ALEMCO, Poughkeepsie, N. Y.

Radio World Wants Pictures of Radio Fans

Have you had a picture of yourself taken in connection with your radio set? If so, we should be glad to use it in Radio World. All you have to do is to send us the photograph, writing carefully on the back your name and address together with a few words of description telling what kind of a set you operate, etc., etc. Send this to the Art Editor of Radio World and we will use it without any expense to you whatsoever in an early issue of Radio World.

Photographs will be returned to senders when accompanied by return postage and when so requested.

Art Editor, RADIO WORLD, 1493 Broadway, New York City.

DO YOU WANT TO BUY, SELL OR EXCHANGE RADIO OR OTHER GOODS? TRY THIS DEPARTMENT AT 5c A WORD

RADIO WORLD'S QUICK-ACTION CLASSIFIED ADS

This department is intended for everybody who wants quick action on short announcements covering the buying, selling, exchanging or general merchandising in the radio and other fields. Readers of RADIO WORLD will find that it pays to read these columns every week. Advertisers will get an eight-day service here—that is, copy received for this department will appear in RADIO WORLD on the news-stands eight days after copy reaches us.

The rate for this RADIO WORLD QUICK-ACTION CLASSIFIED AD. DEPT. is 5c. per word (minimum of 10 words, including address), 10% discount for 4 consecutive insertions, 15% for 13 consecutive insertions (3 months). Changes will be made in standing classified ads. if copy is received at this office eight days before publication. RADIO WORLD, 1493 Broadway, N. Y. C. (Phone, Bryant 4796).

DETECTIVES NEEDED EVERYWHERE—Work home or travel. Experience unnecessary. Write, American Detective System, 1968A Broadway, N. Y.

RADIO SET—Extremely sensitive tuner and one step in 8x18 walnut cabinet. I hear Kansas City Star; Omaha, Neb., etc. Atwater Kent parts. Complete with two WD11 tubes and phones, $70 postpaid. Address, Garth Showers, Tannersville, N. Y.

RADIO FANS AND PROFESSIONALS—How many know the correct CODIFICATION of all characters, punctuations and signs (such as $, %, etc.)? Nine out of ten don't! Our instructor who has had 35 years experience (eight years of which with Uncle Sam) as MORSE and RADIO telegrapher, has just published the only CHART known to give fully the correct codification of all characters of both codes. This chart is indispensable to all up-to-date beginners and veterans alike. Fifty cents (money order preferred) will bring chart; also much information extremely interesting to young men and women (18 to 70) with this information and a little PEP on your part, you can qualify shortly (as scores of our graduates have done) and secure positions paying $1,500 to $3,000 yearly. (See Civil Service Bulletins 215, 357 and 54.) We are registered with the U. S. Civil Service Commission at Washington and can help you. AMERICAN TELEGRAPHIC STUDIO, BOX 793, WORCESTER, MASS.

FOR SALE—De Forest Portable Radiophone Transmitter. 5-watt bulbs; new, $100 net F. O. B. P. O. Box 33, Red Bank, N. J.

CHEAPEST TO BUILD—Easiest to tune. Get particulars Rokay Single Control Hook-up. Describe your set. Rokay Electric Company, Ingomar, Ohio.

LONESOME! MAKE NEW AND TRUE FRIENDS. Confidential. Write DOLLY GRAY AGENCY, Box 186B, Denver, Colo.

VACUUM TUBES REPAIRED. Reasonable. Send for our price list. Vacuum Electric, Station C, Toledo, Ohio.

WANTED—One K. W. used Navy Quenched Spark Gap. Also Price wanted. Harvard Radio Laboratories, P. O. Box 1781, Boston, Mass.

60,000 MILES ON A HOME-MADE RECEIVER. 2,600-mile range. 100 station log and hook-up for the asking. Maitland Roach, 2908 Columbia Ave., Philadelphia, Penn.

LEARN THE RADIO CODE in 3 hours or less by the Corydon Snyder Code Method. Money back if not satisfied. 50 cents postpaid, or particulars for stamp. Corydon Snyder, 1161 So. Ridgeland Ave., Oak Park, Ill.

MAGNAVOX TYPE R3—Latest curvex, improved acoustic models, in original sealed factory cartons. List $35. Introductory offer $25. RADIO CENTRAL, Dept. W, Abilene, Kan.

OLD MONEY WANTED—$2.00 to $500.00 EACH paid for hundreds of Old and Odd Coins. Keep all old money. Send 10 cents for New Illustrated Coin Value Book, 4x6. You may have valuable coins. Get posted. We pay CASH. CLARKE COIN COMPANY, Ave. 83, Le Roy, N. Y.

ALL ESSENTIAL PARTS FOR building Neutrodyne Receiver, complete instructions, etc., $21.50 C. O. D. Reinartz tuning coils, $1.50. R. Schwartz, Buchanan, Mich.

EXCHANGE JOLLY, INTERESTING LETTERS THROUGH OUR CLUB. Betty Lee, Inc., 4254 Broadway, New York City. Stamp appreciated.

SECOND-HAND Westinghouse R. C. Regenerative receiver, consisting of detector and two-step amplifier, $65.00. Three Erla Radio Frequency Transformers, $6.00; Crosley two-step amplifier, $14.00. All of the above is good as new and will work with all standard bulbs. Address Randolph Whitehand, Albany, Georgia.

SUPER-SIMPLICITY CIRCUIT—1,000 to 1,500 miles on one tube, one control, 150 to 25,000 meters. No rheostat, storage battery, vario coupler, variometer, 3-coil mounting, variable inductance, tape or radio frequency. Nothing to guess about. Complete hook-up and particulars. $1.00. No checks. Build your own. Save 50% and get better results. RADIO EXPERIMENTAL LABORATORY, Box 194A, Berkeley, Calif.

FOR SALE—Three Radio Corporation, 200 to 5000 meter radio frequency transformers, like new, fine for superhetroydne, $5.00 each. Fine Phonograph attachments, needle operating kind. Guaranteed good as Magnavox, $10.00 each. Any of above sent post paid, collect, on receipt of $1.00. Everything sold on money-back guarantee. RAYMOND MOORE, Box 404, Lakeside, Ohio.

RADIO WORLD'S

FALL BUYERS' NUMBER

DATE OF IMPORTANT ISSUE—OCTOBER 6

(LAST BLACK FORM CLOSES SEPTEMBER 27)

Hundreds of thousands of radio enthusiasts who will be returning from their vacations, to say nothing of the army of new radio fans that will come into the radio fall season for the first time, will look forward to the buying of sets and general radio equipment in the autumn. Radio World will devote a special issue to these potential purchasers of goods—the **FALL BUYERS' NUMBER.**

Our regular advertising rates will be in force as follows: $5.00 per inch, single column $50, $150 per page, with discounts of 10% four times, 15% thirteen times, 20% fifty-two times (yearly) contract. Classified, 5c a word.

Special service and value to advertisers in Radio World's **FALL BUYERS' NUMBER.** All advertisers who give us copy for quarter page or more space in Radio World's **FALL BUYERS' NUMBER** will, on request, have their announcements appear in **two colors at the price of one**—in case copy is in our hands by September 22.

Radio World is already at work on a country-wide circulation campaign for **FALL BUYERS' NUMBER,** which will be so interesting from a pictorial and text standpoint that it will have an unusually large sale and advertisers will receive unusually fine value.

IMPORTANT NOTICE

While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

Here's an Amateur Who Wants Help

EDITOR Radio World:—I would like to state that I was greatly enthusiastic about radio formerly, but sad to relate my enthusiasm has disappeared entirely due to the following: I possess a Flewelling set that does not work which I purchased in good faith. It worked at first poorly and the tube which I purchased only lasted two weeks. I then had the hook-up changed by someone whom I thought knew something about radio, but really knows nothing, and the set stopped entirely. My proposition is as follows: If any successful Flewelling fan will change the hook-up of my set, which is all that is necessary in order to make it work successfully, I will purchase a new tube and try to regain my lost enthusiasm. This latter will prove whether the readers of the Radio World are really willing to help a radio fan who has tried to reap the joy of radio, but has only suffered disappointment, by their response to the above letter.

I thank you for your kind attention and hope that you will publish the above letter.

Yours respectfully,
JULIUS MILLER.
121 West 114th St.,
New York City.

Not Important at Present to Buffalo

EDITOR, RADIO WORLD: Referring to your letter of July 23rd, it is possible that in the future a municipal broadcasting station may be deemed necessary, but at the present time there are many other things which seem more important.

Yours very truly,
FRANK X. SCHWAB,

HEAR 2000 MILES on a One Tube Set!

Distance, Volume, Very Select Tuning. Easiest Set to Operate. Easily Assembled.

GUARANTEED TO WORK or money back

You Get the Following:

Genuine mahogany cabinet, 1 drilled grade A hard rubber panel, 1 23-plate condenser, 1 variometer, 1 rheostat, 1 tube socket, 2 3-inch dials, 8 initialed binding posts, 3 lengths spaghetti, 3 lengths bus wire, 1 grid leak and condenser, 1 diagram.

All Best Standard Parts.

The Condenser Sensation of Modern Radio

FRESHMAN
NOISELESS
TESTED MICA
CONDENSER
MFG. BY
CHAS. FRESHMAN CO. Inc.
NEW YORK CITY

Through the accuracy and dependability of Freshman Condensers, hook-ups and circuits have been perfected which have completely revolutionized the art of Radio Reception.

These little Storers of energy and rectifiers of Radio Current are the very heart of a well-built radio set.

The proper fixed condenser will make all the difference in the world in the reception, clarity and selectivity your set affords.

Capacity	Each	Capacity	Each
.0001	$ .35	.002	$ .40
.00015	.35	.0025	.50
.00025	.35	.003	.60
.0002	.35	.004	.75
.0002	.35	.005	.75
.00035	.35	.006	.75
.0005	.35	.008	1.00
.0006	.40	.01	1.00
.0008	.40	.015	1.50
.001	.40	.02	2.00
.0015	.40	.025	2.50

The FRESHMAN is so designed that constant equal pressure is exerted on the condenser plates over the entire area. They are the only condensers that do this and therefore the only condensers that avoid noises, which are due to variable pressure on the plates.

At your dealers, otherwise send purchase price and you will be supplied postpaid.

L. W. GOODMAN
DREXEL HILL, PA.

Mr. C. H. Jenkins, Audubon, N. J., writes:—"On July 13th, tuned in WBAP, Fort Worth, Texas, (476 meters), with the GOODMAN, while WDAR (396 m.) and WOO (509 m.), powerful local stations, were broadcasting dance music."

New Magnavox Products

AN announcement of interest to every radio user has been made by the Magnavox Company regarding the introduction of important additions to their already famous Magnavox line of reproducers and power amplifiers. Among these new models are the Magnavox combination sets A-1-R and A-2-R; a new Magnavox reproducer M-1 and a new one stage Magnavox power amplifier A-1. The combination sets consist of the electro-dynamic Magnavox reproducer with 14 inch curvex horn and a Magnavox audio-frequency power amplifier (one or two stage) incorporated in a new type of radio unit which might be termed an "amplifying reproducer."

This combination forms a highly desirable unit for addition to any radio receiving set, giving the user the utmost in adaptability and efficiency.

The rheostats (maximum resistance 30 ohms) and circuits are so arranged in Magnavox combination sets that five-watt transmitting tubes or any type of amplifying tube may be successfully used, thus covering the widest possible range of operating conditions from the smallest home to the concert hall.

These instruments are also equipped with a modulating device for controlling volume, another unique Magnavox feature. Binding post terminals are provided by bakelite panels on the back. The case is of heavy metal forming a shield against outside forces, and is attractively finished in dark crystallized enamel. "On" and "off" switches are provided on top of the case.

Another interesting and important Magnavox product is the M-1 reproducer with 14 inch curvex horn. This instrument is of the semi-dynamic type and has been developed by Magnavox engineers along original principles to meet the requirements of dry battery receiving sets, as it consumes no current from the battery. The Magnavox reproducer M-1 is particularly recommended where low voltage and low current tubes are used. The base is equipped with a five foot flexible cord and has binding posts for extensions. The standard finish is crystallized black but the M-1 is also furnished in special de luxe polychrome finish at the same price.

While these new types of Magnavox instruments are of great interest as being radically different from anything previously manufactured by this company, many users will also welcome the new Magnavox one-stage power amplifier A-1. This, in many cases, is just what is needed to bring in and reproduce the distant stations. It is particularly recommended for use in addition to one or more stages of previous audio-frequency amplification. A-1 is of heavy metal attractively enameled and crystallized. Binding post terminals are provided by a bakelite panel on the back. Any type of vacuum tube may be used.

From the great volume of orders the Magnavox Company is receiving from the trade for these new models it is obvious that the models described above meet a very important need in the radio world.

Sleeper's Two Latest Radio Books

Two new and remarkably good radio books by M. B. Sleeper —one is entitled "Six Successful Radio Sets," with design data and instructions for receiving sets specially selected for exceptionally long distance reception. The other is "101 Receiving Circuits," being a most complete compilation of diagrams including circuits for a regenerative, superregenerative, Reinartz, Flivver, Flewelling, super-heterodyne, reflex and radio frequency sets. Each book mailed on receipt of fifty cents and ten cents extra for postage. Both books for $1.00 and no extra charge for postage. The Columbia Print, 1493 Broadway, New York City.

SPECIAL OFFER
TO NEW RADIO WORLD SUBSCRIBERS:

Send $6.00 for yearly subscription for Radio World (52 numbers) and these two Sleeper Radio Books will be sent you free, parcel post prepaid. This offer good only until September 20, 1923. If you are already a subscriber, send $6.00 NOW for a renewal and books will be sent you.

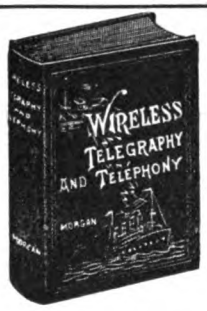
Radio Books for Your Vacation

Telling How to Operate a Radio Set—How to Build a Set—Principles of Vacuum Tubes and Other Radio Problems



Wireless Telegraphy and Telephony Simply Explained

By ALFRED P. MORGAN

One of the most complete and comprehensive treatises on the subject ever published. A study of its pages will enable one to master all the details of the wireless transmission of messages. The author explains in simple language the theory and practice of wireless telegraphy and telephony. 154 pages, 156 engravings.....PRICE $1.50

The A B C of Vacuum Tubes Used in Radio Reception

By E. H. LEWIS

Assoc. I. R. E., and Radio Instructor

Written particularly for the person who "knows nothing about radio," but who would like to gain an understanding of the elementary principles of operation of vacuum tubes and various circuits in which they are used for the reception of radio-telegraph signals and radio-telephone music and speech. Illustrated.....PRICE $1.00

Experimental Wireless Stations

By P. E. EDELMAN

Tells how to make apparatus to not only hear all telephoned and telegraphed radio messages, but also how to make simple equipment that works for transmission over reasonable long distances. Then there is a host of new information included. The first and only book to give you all the recent important radio improvements, some of which have never before been published. 392 pages, 167 illustrations.....PRICE $3.00

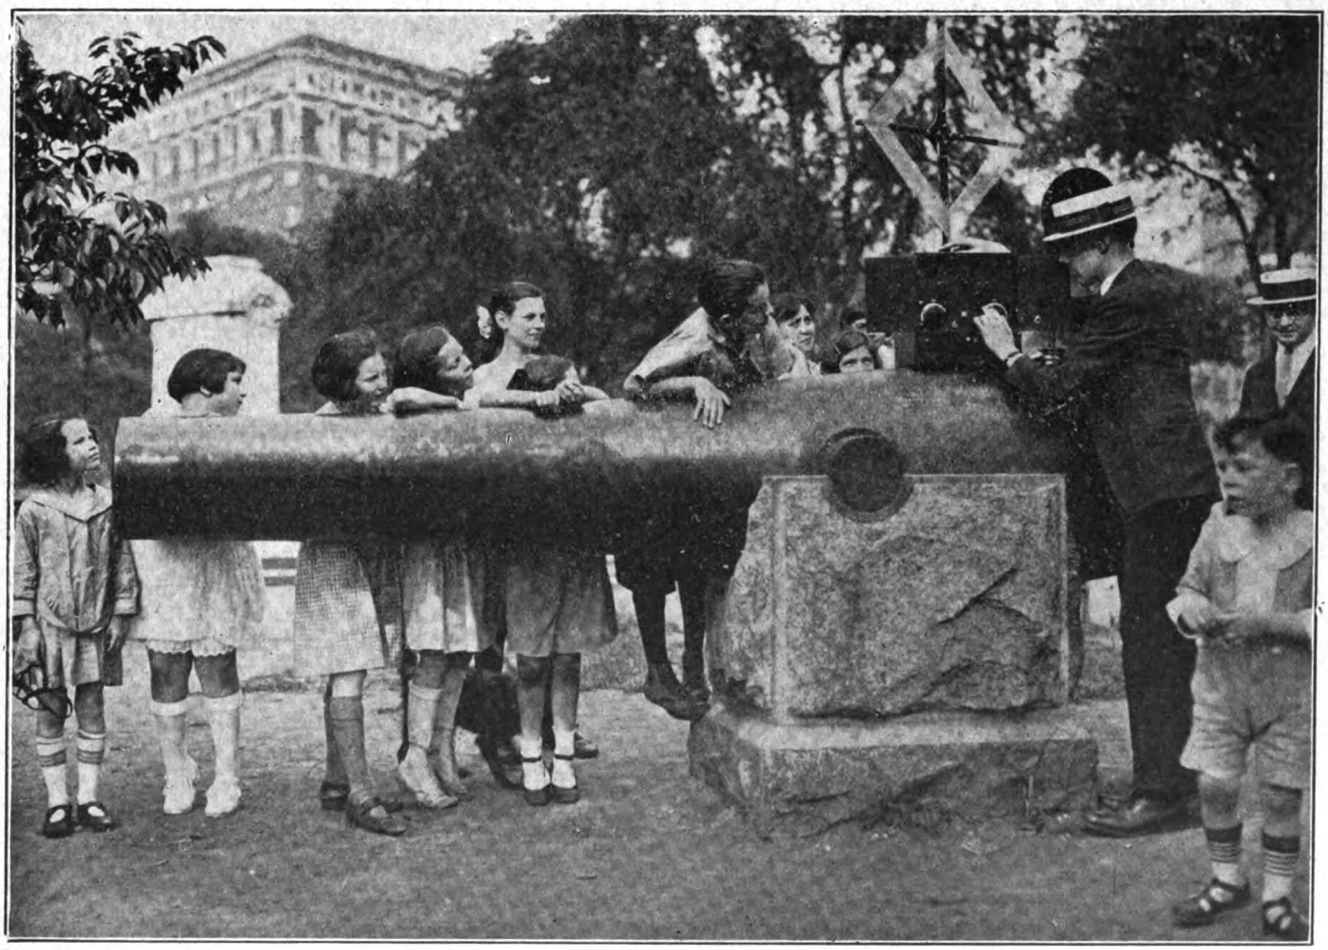
RADIO AMATEUR EXPERIMENTS IN NEW YORK CITY PARK



(C. Kadel and Herbert)

Richard Bourne, New York amateur who is a skeptic, is here seen observing the effect of a large steel mass on radio signals and tuning. He found out that the signal strength remained practically the same, but that the directional effects of the loop were seriously harmed, and in most cases the loop was entirely non-directional. All positions were tried out, both on top and under the cannon, which happened to be the largest mass of solid steel in the vicinity. One would naturally expect that the presence of such a large mass of metal would tend to absorb a great amount of the radio waves in its immediate vicinity, but such was not the case. Probably the fact that it was partially insulated by resting on a granite base had a lot to do with it.

Why Federal Standard

Receiving Sets should be your choice

FEDERAL Standard Receiving Sets offer the most in real entertainment. The reproduction of voice and music is clear, accurate and pleasing.

The sets are made entirely of guaranteed Federal Standard parts. Each part working in perfect harmony with all the others in the set produces a quality and range of radio entertainment which cannot be equalled by instruments at anywhere near the price range of the Federal.

Distant stations can be tuned through local stations and the operation of the set is so simple that any man, woman or child can easily master it.

Almost any aerial can be used satisfactorily, including small indoor loops or wire around the moulding of the room. It is, therefore, the ideal set for the radio enthusiast who wants to receive both local and distant stations but cannot use an outside aerial.

Federal D. X. Type No. 58 Receiver, $116.00 each (without tubes, batteries or headset). This receiver is exceedingly sensitive and makes reception possible over ranges greater than can be accomplished with ordinary means of amplification. It is unsurpassed for local work also. Ask your dealer for a demonstration.

The Design of Very Compact Sets

By Kenneth Malcolm, A. I. R. E

IT seems that radio fans like to experiment with odd and bizarre contraptions more than any other group of human beings in the world. They develop and construct some of the most unique looking sets and work with the strangest hook-ups. It is a wonder they have such success as they many times do. The craze now foremost seems to be the building of very small and compact outfits, such as can be put in cigar boxes and the like. Leaving out the very tiny untuned sets, some of the very small ones do remarkable work, though it could not be expected that no efficiency would be lost in reducing the size so materially. The main trouble, when these sets do not work as well as they might, is generally due to incorrect design and the use of incorrect hook-ups for a particular group of apparatus. The following paragraphs will attempt to give some data on the fundamental design of these small sets, so that those who are experimentally inclined can go about their construction with the knowledge that the set will work right when it is finished. However, it is only suggestive, aiming to encourage original ideas rather than to array a lot of conventional dogma.

The only small set that is worth bothering with by those who are really serious and who desire consistent results, is one that is tuned, no matter how simple the tuning device may be. A set that can be included in a very small measure is shown in Fig. 1. Either a crystal or a tube may be used as a detector.

In this set the tuning coil is the part that will have to be constructed to suit the individual requirements. Such a coil may be made in one of many forms, as long as the wire takes the form of a coil. Mailing tubes or cardboard containers of all kinds may be used to wind the wire on. After you have selected one of the style you need, it is best to thoroughly impregnate it with some good insulating varnish to stiffen it and at the same time make it waterproof. It is best to have the tube as near round as possible; although square tubes have been used successfully. Next comes the wire. This should be not smaller than No. 26, for past this point the wire has a very high resistance, and sometimes enough to dampen out the waves entirely and thus prevent reception. Enameled wire takes up the least space, although single silk or single cotton covered wire would be better on account of its smaller dielectric constant.

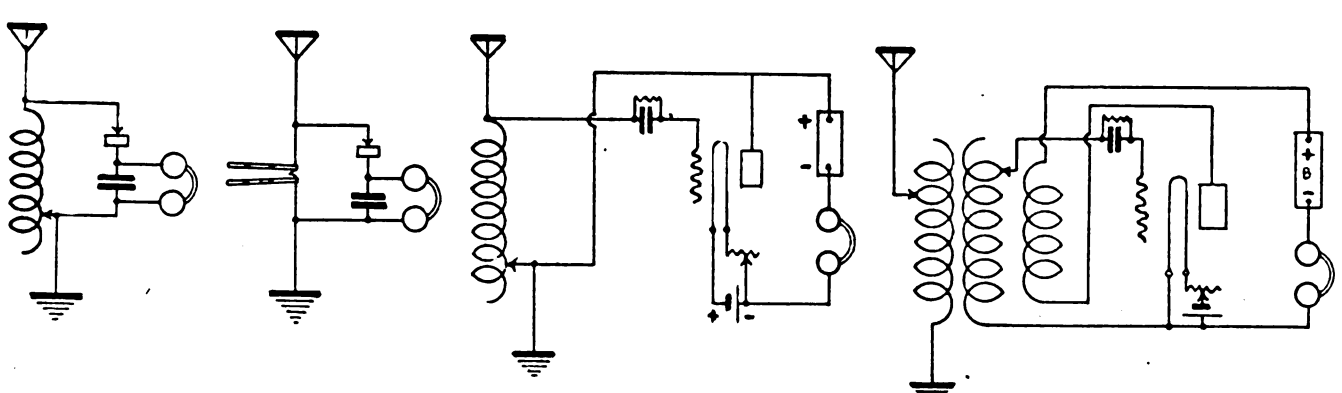
The number of turns you will need depends upon the wave length of the stations you desire to receive, the diameter of the tube, and the length of the aerial you intend to use with the set. It may range anywhere from 20 to 100 turns for short wave reception. However the correct number can easily be found by experiment.

With this type of coil, some sort of slider or tap and switch arrangement is necessary in order to be able to vary the inductance. Of course, it could be fixed and a variable condenser used across it, but this would to a certain extent defeat your purpose of building a very small set.

Where extreme compactness is desired, the spiderweb coil lends itself very readily to adaptation. These coils can be used the same as the cylindrical coils in any of the circuits. A switch and tap arrangement in this case would be more convenient and preferable to a slider.

A way to use two spiderweb coils as a variometer to be used as the sole tuning unit is shown in Fig. 2. Here, both coils are wound with the same number of

(*Concluded on next page*)



Four simple circuit diagrams particularly adapted to extremely small sets. The first two are crystal receivers and the last two are small tube receivers. The first is a single slide tuner, the second a spiderweb variocoupler, the third an ultra-audion single tube circuit, and the fourth a three-circuit regenerative.

Impressive Harding Memorial Services Broadcast from Station WJAZ

By R. H. G. Mathews

THE story of the first attempt of a broadcasting station to visualize by means of music and the spoken word a current event of large significance —in this case the final tribute paid President Harding in the city of Washington—doubtless will be a source of intense interest to thousands of broadcast listeners.

The unseen audience of WJAZ—the Zenith-Edgewater Beach Hotel Broadcasting Station at Chicago—were carried in the imagination to the starting point of the funeral cortege and accompanied the sorrowful procession step by step up Pennsylvania Avenue, now to the tune of "Abide with Me," again to children's voices singing "Nearer My God to Thee," again to the inspiring strains of "Onward Christian Soldiers," the impressive Chopin's Funeral March, President Harding's favorite, "Lead Kindly Light," and so on up the wide stairs of the Capitol building. Then as strong male voices sang "Lead Kindly Light," the coffin mantled in the flag was placed on the catafalque in the rotunda. The brief and impressive funeral services followed and were concluded by the sounding of taps.

When the procession got under way the bells of St. John's Episcopal Church began to toll "Nearer My God to Thee" and continued until Reverend J. Freeman Anderson's voice was lifted in prayer. "Nearer My God to Thee," played by the church chimes fell on the ears of the mourners loud and clear at first, fainter and fainter as the procession neared the Capitol—the key-note, as it were, of the pathethic spectacle.

All this passed before the mental vision of the listeners with the aid of word pictures painted by N. A. Fegen at Station WJAZ, the program spoken by E. F. McDonald, Jr., and Dr. Anderson's invocation read by Mr. Fegen.

WJAZ has been submerged since with letters of praise for the effectiveness and sincerity with which the event was handled. To some of the listeners it was so realistic as to provoke tears.

Plate Batteries

IN nine cases out of ten half the troubles brought to my notice are caused by faulty plate batteries, half of which were cheap when they were bought and the other half were bought so long ago that they were long past their useful life," is the remark of a dealer who has been making an investigation of the troubles surrounding receivers. This is a true statement and one that is not regarded as serious by the average fan who has entered the field during the past year or two.

In the matter of constructing plate batteries the principle is fine. But stop to consider for a moment that over nine-tenths of those that attempt this branch of the work do it mainly from the experiences related by another. It takes real experience to make storage batteries, and even greater care to make those for the plate circuit. Unless you understand what to do and how to do it, the cheapest way is to buy a good standard B battery—with the shelf life and the date marked on it plainly!

(*Concluded from preceding page*)

turns, and fastened together at one side by a hinge made of some flexible insulating material. In this case no taps or slider are needed, the tuning being done by changing the relationship between the coils.

That mutual inductance idea suggests another tuning method—that of varying the distance between the individual turns in a coil. The idea is used quite successfully on a little receiving set which is on the market, and which is no larger than an ordinary pocketbook. In this set about 30 turns of wire (the turns each being about 2″ in diameter) are grouped together in a bunch. The only support they have is afforded by a little strip of tape which binds one side and fastens it to the base of the set. By spreading apart the turns on the free side, the inductance is decreased and hence the wave length. Another way to use the same principle would be to make a coil of some good springy wire, fasten one end and draw out or let in the other end, accordion fashion.

A very good hook-up for use with a tube in connection with a midget set is the ultraudion shown, in a simplified form, in Fig. 3. If the tuner is capable of fine tuning, this set will regenerate very nicely. Where a short wave length range is all that is needed, the variometer idea in Fig. 2 would do fine. A tuner with a slider would do quite well, but it would be best to use a vernier condenser across it to tune in between the turns. A single spiderweb coil with one of those new thin variable condensers would allow the building of a set of this type that would be extremely compact. A variable grid leak would help.

The hook-up shown in Fig. 4 is a standard one, and would be excellent for our work if spiderweb coil were used for the inductances. A mounting should be arranged somewhat similar to the three-coil honeycomb mountings, so that the primary and the tickler coil can be adjusted in their relationship to the secondary.

The primary tuning need not be critical and taps may be taken off to switch points at every few turns. The secondary needs a much finer adjustment, and a switching arrangement must be provided that will cut in single turns, or else a vernier condenser must be used across it. The tickler coil should have about a third more turns on it than the secondary.

Most any tubes may be used for these sets, but the dry cell tubes are the most sensible to carry out your purpose more fully. The WD11, WD12 and the UV199 lend themselves admirably, the latter tube, especially, because flashlight cells can be used to light the filament.

Whatever way you build your set, remember that the same principles apply. A tuning coil is the same whether it is wound around the end of a cane, around the crown of a hat, or around one of the more conventional tubes. The writer has constructed a number of these radio freaks and they worked very well, everything taken into consideration. However, there is something very important that must not be overlooked, and that is the joy that was derived from conceiving, designing, and constructing them.

The Practical Side of Vacuum Tubes

By C. White, Consulting Engineer

ANY one who attempts to cover all about vacuum tubes in one article would indeed be rather crazy. There are at present, in many technical libraries, great numbers of books more or less directly connected with the theory and operation of vacuum tubes of some kind or other. Hence what I shall say in this brief article should only be considered a mere drop in the bucket in the largest possible terms. Over a year ago I wrote a brief history of the vacuum tube, but in this article I shall deal with the practical side of its theory and operation. We all are quite familiar

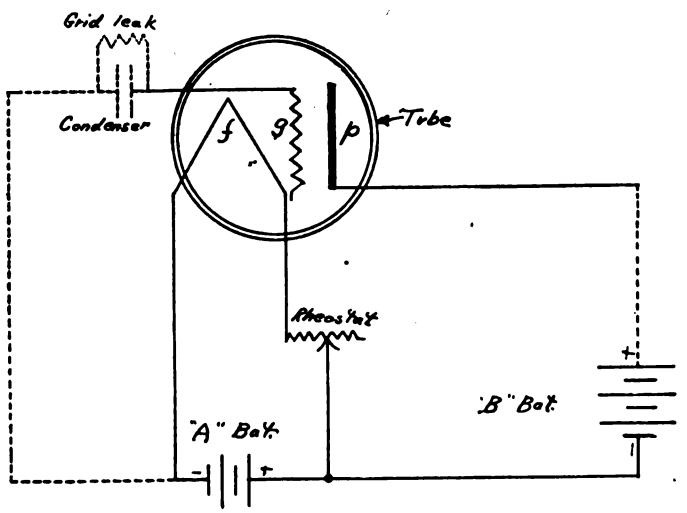

Fig. 1. General schematic representation of a vacuum tube showing the elements and connections.

with the theory apparent when a pot of water boils over a fire. The water sends off into the surrounding adjacent space water vapor or steam.

Exactly the same thing, or the analogous thing, exists when we pass a current through a filament. The current causes the filament to be heated up in the same manner as the fire under the pot, and as a result of this heating electrons are given off instead of steam. We can readily see steam vapor, although steam itself is invisible, but there is no actual form the electrons can take to show us that they are there. The amount of steam that will be generated will depend upon the rate at which heat energy is supplied to the pot and the pressure of the surrounding atmosphere. The analogy is exact with a lighted filament; therefore, to get the best emission of these invisible particles carrying electrical charge it is necessary to remove the air surrounding the filament, hence the use of a vacuum of either high or low amount of evacuation. It is of interest to know that these electrons carry negative charges of electricity. The actual theory behind this statement is rather long and involved in its proof and discussion, and it is well enough to accept it on faith since it has been definitely proven by renowned scientists.

Keeping in mind the case of a kettle of water over an open fire, let us continue an analysis of the vacuum tube action. The "A" battery supplies the energy to heat up the filament which, when the correct temperature is reached, emits an invisible electron vapor in the same way as a kettle emits steam vapor. Now if we should cover the kettle with a lid and have a suction pump so connected to the lid as to draw off the steam vapor at a certain rate then we will have the same action as the positive charge on the plate performs. The positive charge on the plate of the vacuum tube acts as a magnet to the negatively charged electrons which "boil off" the filament.

In other words, the plate gives directional motion to the electrons which would otherwise be more or less stationary. On moving from the filament, where they are generated to the plate, it is necessary for the electrons to pass through a sieve-like structure known as the grid. It is plain to see that this grid structure can be made to accelerate or retard the motion of the electrons on their way to the plate, much in the same way as a valve in a water main can accelerate or retard the flow of water, depending on how far it is open. Electrically, the grid performs this action by taking on a positive or negative charge. When a positive charge is on the grid the magnetic attraction in the direction of the plate is greater and when a negative charge is on the plate the magnetic attraction is decreased. The old rule obtains—like charges repel and unlike charges attract. The total amount of electrons generated will depend upon the heat of the filament, the material of the filament, the amount of vacuum, the amount of positive charge on the plate and the action of the grid. Of course, there is a definite limit, which is the determining limit in tube design.

Vacuum tubes are listed according to kind of fila-

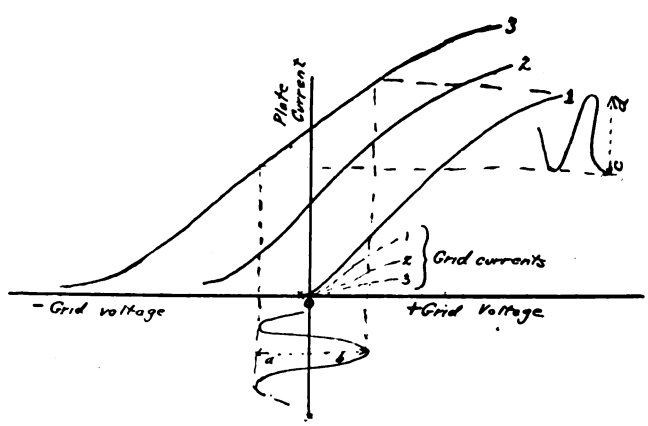

Fig. 2. Characteristic curve of a receiving tube showing the relation of the grid voltage and the plate current.

ment, amount of vacuum, and the power generated. The kinds of filaments now on the market are the oxide coated filament, the pure tungsten filament, and the thorium coated tungsten filament. The Western Electric tubes known as the VT-1 or J tube and the VT-2 or 216 A tube are excellent examples of a filament coated with an oxide which has a property of giving off a high amount of electrons at a low operating temperature, hence giving a long life. The pure tungsten filament is more common and the UV200 or C300 are examples.

This type of filament operates at a high temperature and care must be exercised to see that it is not exceeded or its life will be greatly shortened. The new thorium coated filaments, as the UV199 and the UV201A, operate at a much lower temperature than the pure tungsten filament, hence giving long tube life. The terms hard and soft are general terms relating to the relative amount of evacuation. A hard tube is one

"Standing By" For News That Shocked the Continent

ANOTHER instance of radio serving as an almost instantaneous means of advising of President Harding's death is recounted by an official of the Department of Commerce who was touring in upper New York on August 6.

Following a cordial reception at the farm of W. E. Carpenter, a vineyardist living near Burdette, N. Y., who had not heard anything over a radio set, the government official set up his three-tube, portable set and tuned in on Schenectady. Neighbors began to gather round the loud speaker. The concert ceased at 9:30 and the operator tuned in WDAP, the Chicago Board of Trade, which was broadcasting musical selections. Suddenly, a vocal selection was interrupted by a message to stand by for an important announcement. The farmers and their families, now numbering over a hundred, not more than one of whom had heard a radio message before, stood in suppressed excitement. The station then announced the reported death of President Harding and explained that it was being verified. This was accomplished at 10:53 Eastern time, and the country people in the neighborhood were thus advised of the national calamity eight minutes after the official announcement was made in San Francisco. It proved a tragic introduction to radio for these novices. Later other stations broadcasting the sad tidings were also picked up as the message sped on its way eastward over press wires.

The midshipmen of the navy cruising in Europe were drawn up on deck for a local ceremony where a radio dispatch to the Admiral of the Fleet advising of the death of their Commander-in-Chief was read. Immediately the ceremony was cancelled and flags half-masted.

Radio, it would seem, did more than any other method of communication to speed the tragic announcement around the world.

New Out-door Radio Sport at Chicago Ham Convention

CHICAGO, ILL.—A new sport involving a unique principle of radio will be introduced for the first time at the Second National American Radio Relay League Convention, which is to be held here September 12-15 under the auspices of the Chicago Radio Traffic Association with headquarters at 959 Rookery Building, Chicago.

Several hundred tiny loop receiving sets are to be loaned by the Drake Hotel to delegates and will be used by them to locate a "hidden" transmitting station. The method used in finding the position of an unknown station is somewhat similar to that employed by navy shore stations in determining the location of ships.

A vessel coming into port may have lost its bearings and the captain, who has been unable to make observations on account of fog, or a cloudy sky, will instruct his radio operator to advise shore stations of this condition, and the latter make "cross bearings" by means of loop receivers, discover the exact location and report it.

Usually when two shore stations work together and advise each other of their observations by land wire, the exact position can be found in a few minutes, but when only one loop set is used and this by someone on foot in the midst of city traffic, the problem is more difficult and requires real skill.

The operator must turn the loop antenna in such a direction that he can tune the transmitter in or out by a slight variation of the finder. After noting the place where this observation was taken he moves several blocks to the right or left and again tunes in his loop receiver as before.

He then draws an imaginary line from both points in the general direction of the "hidden" station and proceeds toward the place where they join together. Frequently this whole operation has to be repeated many times.

(*Concluded from preceding page*)

that has been almost completely drained of gas, such as the UV201A, and a soft tube is one that has a little gas remaining, such as the UV200. Of course, there are many tubes that lie between the two limits which we might call medium. The size and spacing of the elements largely determine the amount of power the tube can generate, but for reception the non-power tubes are employed. For power amplification and transmission larger tubes, which can handle the required amount of power, are used.

In Fig. 1 is illustrated the general schematic representation of a vacuum tube. The grid is represented by the letter g, the filament by f, and the plate by the letter p. The dotted lines replace the coils and other working apparatus of a radio outfit since we are here concerned only about the tube and the batteries necessary to operate it. In Fig. 2 is shown the characteristic of the tube. It is a plot of the performance of a given vacuum tube showing the relation of the grid voltage and the plate current. In other words it shows the existing relation between the two. The solid curves marked 1, 2, 3 are drawn for three separate plate or "B" battery voltages. The curve with the highest number indicates the relation with the highest "B" battery voltage on the plate. The small dotted line curves marked similarly represent the amount of current relatively flowing in the grid circuit for the given plate voltage. Please note that the higher the plate voltage the less the current flowing in the grid circuit.

If we should desire a given tube to act as a detector of radio signals the tube should operate with a plate voltage which will allow it to work as outlined by curve 1. It is plainly observed that this curve ends at the point marked x and you will note that when the grid voltage is negative there is no plate current; therefore, only the positive grid variations will appear in the plate circuit current. This means that the signal is rectified or detected. In order to properly regulate the grid current that flows at the lower plate voltage, such as used with the tube as a detector, a grid leak and leak condenser is employed. If the tube is to be used as an amplifier it is important that the negative as well as the positive variations of the grid voltage should be passed along to the plate circuit amplifier. Hence we must work on characteristics 2 or 3 since 1 only passes on positive grid variations. Assuming we work with plate voltage 3, then, for example, the grid variation a-b will appear as the current variation c-d in the plate circuit.

Blind Police Hero Builds His Own Set

THE fact that radio brings contentment is a proven and established fact. Many helpless humans who cannot stir are kept happy by their radio sets.

One case of note is that of Patrick O'Keefe, blind hero of the New York Police Department. He lost his sight in the performance of his duty by a pistol bullet. For many months, handicapped as he was, he was extremely unhappy. Naturally a very active man he could not accommodate himself to enforced idleness. Being, however, of a mechanical turn of mind, he thought of radio, and with the help of a friend built a crystal radio set.

(C. Keystone Views)
Patrick O'Keefe listening in on his receiving set.

Now, though unseen and unseeing he is the guest of many an important dinner and reception that is broadcast, where the microphone acts as his "eyes." He chuckles heartily at the jokes, enjoys the music and through his mind's eye, though really in his arm chair, he is sitting right next to the toastmaster, or has a table next to the orchestra that is playing. He even "sees" all the popular plays that are broadcast. It is said that blindness sharpens man's perception and imagination, and therefore he can readly have a ringside seat at all the fights, with all the comforts of his home and easy chair besides.

Radio has probably done more to alleviate the suffering of the afflicted than any agency human or otherwise. It brings contentment to those that are used to action, by keeping their minds active and away from their trouble, which doctors tell us helps more than medicine. To substantiate this fact, for it really is a fact, think of the number of hospitals that have called radio to the fore in cases where the brooding of the patient would seriously deter his cure or treatment. And for a man that has been active, as Patrick O'Keefe surely must have been, the loss of his sight is really something to brood over, brave as he may be. But radio does not give him the chance, for you cannot "listen in" and think of other things.

"Big Bill" Edwards Radios Address on Boy Scouts

BIG BILL" EDWARDS, former Collector of the Port of New York and well-known former athlete, recently gave a talk from Station WEAF on the subject of Boy Scouts. "Big Bill," who is a lover of the great outdoors and an ardent supporter of the Boy Scout movement, spoke for the Boy Scouts Foundation of Greater New York.

Many listened with interest to the talk, especially the Boy Scouts in camp, and those having radio sets were sure to be popular when "Big Bill" made his address. The Honor Scouts who were allowed to be present at the studio at the time the address was made were highly impressed with the entire proceedings, especially as they were the only people allowed in the studio at the time the address was made.

The illustration shows "Big Bill" Edwards making his address attended by the Honor Scouts. During his long political career "Big Bill" never talked to as large or attentive an audience as on this occasion.

(C. Photonews)
"Big Bill" Edwards attended by Boy Scout Honor Squad.

Amateurs Pick Up MacMillan Message

JAMES A. TRAINOR, of Dorchester, Mass., and R. B. Bourne, of Chatham, Mass., both radio amateurs, on August 29 picked up a radio message from Captain MacMillan's Arctic ship "Bowdoin." The news sent out by Operator Mix, of the "Bowdoin," was "Located latitude 78° 30'," and was the first word received by the world from the explorers in 32 days.

This would locate the expedition on the northwest coast of Greenland, about 2,400 miles north of where the message was received and within the auroral band.

After proper verification, it would seem that one or both of the amateurs named will be entitled to the receiving set offered as a prize to the first amateur to deliver the next message from Captain MacMillan to the Zenith Edgewater Beach Hotel Broadcasting Station, Chicago, announced in last week's RADIO WORLD.

France and America Standardizing Waves

By Carl H. Butman

WASHINGTON, D. C.—In an effort to standardize radio frequencies used in trans-Atlantic communication, the Navy Department is co-operating with the French Government and once a month the frequencies of the Annapolis and Lafayette radio stations are recorded and compared. Transmission on standard frequencies, or wave lengths, is essential to efficient communication in order that all stations can keep to the wave lengths assigned them by national or international law. Special efforts are now being made by the United States and foreign governments to keep all their stations on the prescribed waves and it is essential that their standards be equivalent and their instruments be calibrated.

Every month special signals are transmitted from Lafayette and Annapolis on known frequencies between 16 and 17 kilocycles. These signals are observed simultaneously at the Naval Radio Research Laboratory at Bellevue, D. C., and at the French Military Radio Telegraph Laboratory at Paris. The stations are advised by radio and also by mail of the exact frequency measured on receipt and thus the check is made. If an error of more than one-tenth of one per cent. is found, further tests are made and the apparatus for measuring frequencies at both stations is also calibrated. Eventually, perhaps within a year, it is hoped by naval radio experts that the error can be reduced to one-hundredth of one per cent., but at present they are satisfied with an error of less than one-tenth of one per cent.

The basic measure of radio-frequency is a standard tuning fork and upon this is calibrated a multi-vibrator on which a mere beat can be measured. Wave meters are checked against the multi-vibrator and are used in measuring the frequencies of waves used in commercial and official communications.

The frequencies of the naval radio stations at San Francisco and Annapolis are also compared periodically by the laboratories at Bellevue and Mare Island, so that the naval standard frequency measure is kept constant throughout the United States. Eventually the Bureau of Standards will test the waves assigned to stations and calibrate their instruments. The work of the Navy Department is carried on primarily for the efficiency of its own communication service. As there are hundreds of naval ships and a large number of shore stations, each operating on distinct waves, it is essential that they stick to their allotted frequencies and not interfere with other ships or stations.

When all stations maintain their proper wave lengths or frequencies exactly, tuning in will be more readily accomplished, it is pointed out, the process approaching the simple adjustment of a dial to a known position. Perhaps dials will be marked "London," "Paris," "Berlin."

The Bureau of Standards has already sent out standard waves at known frequencies for the benefit of eastern amateurs and broadcasters, so that these stations can calibrate their instruments and set their transmitters on their proper frequencies. This work shortly will be put into definite practice, it is understood, and the stations which do not keep their proper waves may be closed.

Cavalry to Have Portable Radio Sets

A REPORT on the requirements of radio equipment for the cavalry has just been completed by a board of cavalry and signal corps officers which met recently at Fort Bliss, Texas. While the recommendations of the board have not yet been made public, it is known that they contain considerable data as to improvements on existing radio sets together with suggestions for the signal corps in designing new apparatus for the use of cavalry in the field.

Both cavalry squadrons and regiments are now equipped with pack radio telegraph sets knowns as SCR-127, a tube set capable of transmitting about 60 miles. The apparatus, which weighs 200 pounds, is split up when transported between three horses or mules, one pack comprising the generator, another the batteries and aerial and the third the set itself with spares and auxiliary equipment. Brigade headquarter troops are outfitted with more powerful sets, designated as the SCR-130, and having a slightly longer range. This set is now transported on a wagon.

Recommendations of the special board include methods of transportation, whether horse pack, wagon or motorized; power plant, extent of wave band, range, weight, and other specifications for the new issue of radio equipment for cavalry. It is believed that motor equipment for the larger units such as brigades will be recommended, and that the range of the sets will be extended to over 60 miles. Radio telephone equipment will not be assigned, since these sets are of greater weight than it is practical for field transportation and radio telegraph seems to serve the needs of the cavalry. The signal corps is understood to be awaiting the report of the board before undertaking improvements on old sets or developing new equipment.

NC-4 Had First Radio Aircraft Compass

THE use of the radio compass on aircraft of the navy dates back to the trans-Atlantic flight of the three NC boats in May, 1919, on which occasion Commander Reed of the NC-4 made a very practical use of his direction-finding instrument.

In taking off from Horta, Azores, to Lisbon, the third leg of the trip, Commander Reed in his report states that a rather hard "porpoise," or bump on the surface of the sea, was made. This caused one of the gimbals of the navigator's compass to jump out, causing an error of 7 to 8 degrees, although it was not known until some time later, he writes. The first destroyer stationed on the route was picked up apparently in its proper place, but it must have been south of its position on a line to Lisbon it was discovered later. The NC-4 passed ten to twelve miles to the south of Destroyer No. 2, only the smoke being sighted, while No. 3 was not seen at all.

Commander Reed here decided he was far to the south of his route and headed north. With the aid of his radio compass he picked up Destroyer No. 4 just off his port bow, and then continued eastward sighting all the remaining destroyers as he proceeded to Lisbon.

If he had not been able to check his position, or locate the fourth destroyer by means of the radio compass, it is possible that he would not have reached Lisbon, and the trans-Atlantic air trip might never have been completed.

To-day, many naval long-range aircraft, including the ZR-1, airship, are fitted out with radio compasses in the interests of safety and so that navigators can check their positions independently of their regular compasses.

Converting the Spark Coil

By Byrt C. Caldwell

THE spark coil is doomed to die as far as damped wave radio transmission is concerned. The great interference which the spark set causes, and the short distances which it covers, make it unsatisfactory for the up-to-date amateur. The C. W. or I. C. W. set is undoubtedly ideal. When handled with reasonable care, this causes no interference to the broadcast listener, and with the same amount of power has a reliable range of at least fifty times the distance of the spark. Interference among the amateurs themselves is also reduced to a minimum, as the emitted wave is extremely sharp.

I will not go into the details of the reasons why the undamped wave set has such a high efficiency when compared to the damped wave set, as this has been explained

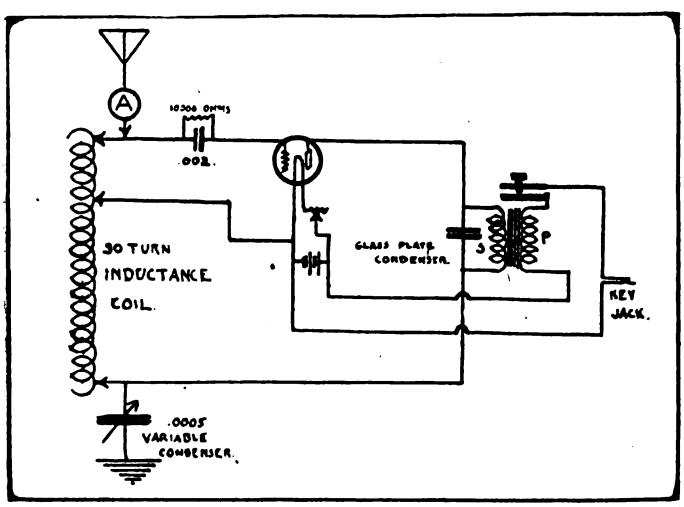

Fig. 1. Circuit diagram illustrating the use of a spark coil for CW transmitting. Extremely simple and efficient, and, if well tuned, is capable of much longer distances than could be obtained by the spark coil alone.

dozens of times in magazines and books which anybody may easily obtain.

If you have a spark coil set at the present time and, at a cost of several dollars, wish to change it into a set which has a range of several hundred instead of several miles, and which causes a minimum of interference, you would do well to construct the set described below.

It is very simple and is as easy to build as a regenerative receiving set. In the diagram, the full lines show the layout of the front of the panel and the dotted lines show the arrangement of the instruments at the rear of the panel. This panel layout should be followed carefully, as it is planned for the shortest possible leads and for maximum efficiency. The hot wire ammeter is in the upper left hand corner of the 7" x 12" panel. This, while not absolutely necessary, should be used if you wish to get the best that is in the set. A miniature tungsten lamp may be used instead. When tuning, adjust the set until the lamp lights the brightest. The variable condenser, which has a capacity of .0005 mfds., is in the upper right hand corner of the panel. This condenser should preferably be of the two-plate mica dielectric type. The rheostat is mounted in the center of the panel and the binding posts for the coil and filament are directly underneath this. The antenna and ground binding posts are both at the top of the panel and the jack for the key is on the right side of the panel. The instruments are arranged as follows: The spark coil is on the right hand side of the panel and the glass plate condenser is to the left of this. The tube is directly in back of the rheostat and the inductance is behind the ammeter and the tube. This is supported by brass strips fastened to the edges of the coil and the base.

The spark coil may be a ½" to 1" instrument. If a coil which has only three terminals is used a separate battery must be used. The glass plate condenser is necessary to reduce the secondary voltage of the coil to a value where it will not damage the tube. A fairly large condenser will be necessary for this purpose. The size will vary, according to the coil used, and the voltage requirement of the tube. The larger the spark coil, and the lower the voltage required by the tube, the larger the condenser will have to be. One for use with a 1" coil and a five watt tube can be made by separating about 25 4" x 6" sheets of tinfoil with 5" x 7" photographic plates. These can probably be obtained for nothing from your photographer, as the manufacturing companies are not buying them back at the present time. Be sure to clean the plates absolutely free of the last trace of emulsion. The tube should be a five watt transmitting tube, although a hard receiving tube, such as the UV201A will give good results up to a distance of 100 miles or more. With this tube the condenser across the secondary of the coil must be larger than specified above. The inductance consists of 30 turns of bare No. 12 or No. 14 copper wire, stranded preferred. It is wound on a form made of bakelite or hard rubber strips, either cylindrical or square in shape, and about 4" in diameter and 6" long. Fasten the wires securely by running the ends through holes drilled in the form. Do not use shellac. The bare wire, and the frame instead of a solid bakelite form, are used so that air is employed wherever possible as an insulator. Lugs are soldered to each turn of the inductance, so that the set may be tuned by varying the number of turns used. The grid leak should have a 10,000

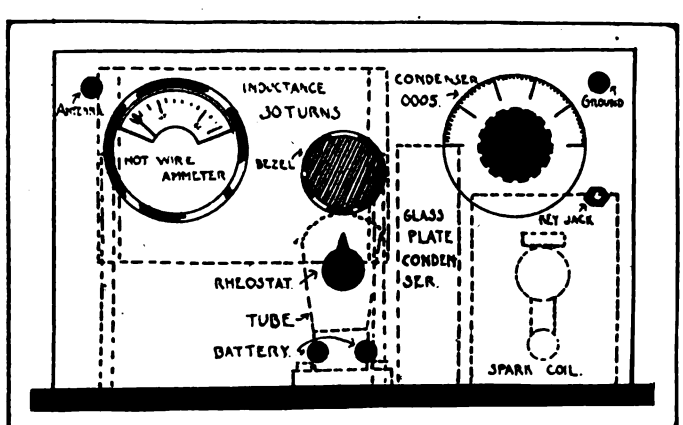

Fig. 2. Suggested panel and instrument layout for the spark coil transmitter.

ohm resistance. The grid condenser may have a capacity of about .002 mfds. The condenser in the ground lead should have a capacity of .0005 or .001 mfds., and should have a mica dielectric.

The hook-up shown is one of the simplest and most satisfactory. This set gives a tone which may be varied by means of the vibrator of the coil. The connections from the secondard of the coil should be reversed and left at the connection which gives the greatest antenna current. In wiring the set, use bus wire, and solder every connection. This is especially important. You will never get results with loose connections and poor wiring. Bare wire should be used, except where two wires cross very close to each

A Reader Objects to Antenna Figures

EDITOR, RADIO WORLD:

I have just been reading your article called "Properly Installed Antenna Greatly Aids Better Reception" (RADIO WORLD, August 25, 1923) in which you state that a height of 40 feet and a length of not more than 75 feet for a receiving antenna has been found most suitable for good reception.

According to my personal experience, I think these statements are absolutely wrong when made without qualifications. With a three-tube regenerative receiver, which I use, an antenna 250 feet long gives far superior results to an antenna of half the length. An antenna 80 feet high gives results far superior to those obtained with an antenna 40 feet high. These are results of actual experience.

I am now using at the Eastern Yacht Club, Marblehead, a single wire antenna, which with the lead-in, measures 250 feet and I am getting very satisfactory results on all wave lengths from the shortest broadcasting station upward to 20,000 meters. Signals come in very clearly and satisfactorily.

In your article you state why the height should be limited to 40 feet but you do not state why the length should be limited to 75 feet.

In my opinion such unqualified statements do great harm. An antenna which will work with one receiving set satisfactorily may not work with another receiving set satisfactorily. This important statement you have left out of your article entirely.

I have in my room beside the regenerative receiver a four-tube crystal detector reflex receiver which connected to the long antenna above referred to brings in ship signals of great clearness and distinctness. These I suppose are on 600 metres but ordinarily it will not bring in broadcast stations at all.

To get broadcast stations with this reflex receiver, I use a wire strung around my room on the floor simply fastened to the corners. This wire is about 45 feet long and brings in Chicago stations, even in summer weather, more than loud enough for a loud speaker.

I have in my home in Concord a cage antenna which I use for receiving which is 4 feet in diameter and composed of eight wires 100 feet long with a single 7-20 lead-in. My idea in building this form antenna was for its ultimate use for transmission but it is too long for 200 metre work and I do not care to cut it down because I get such marvellous results with it in receiving all wave lengths from 150 metres to the highest used in transatlantic work. This antenna is 80 feet high.

At my summer home at Seal Harbor, Maine, I had a long single wire antenna, probably 250 feet, on which I got Cuba in July on a three-tube regenerative receiver, using only two tubes and also using coils 25-35-50. I could get the shortest amateur stations much better than on a short 100 foot single antenna which I put up especially for short wave lengths. So far I have found with this regenerative receiver the longer and the higher the antenna, the better the reception.

I find that in almost everything connected with radio, positive statements such as you made in your article on antennae are always wrong. Yours very truly,

W. K. SHAW.

160 State Street, Boston, Mass.

New Class A Stations

Two limited commercial or broadcasting stations were licensed during the past week by the Department of Commerce:

Call	Station	Class	Frequency Kcys.	Wave Length Meters	Power Watts
KFJR	Dixon, Ashley C. & Son, Stevensville, Mont.....	A	1160	258	50
WTAJ	Radio Shop, The, Portland, Maine	A	1270	236	50

Distance

MANY fans who do not really understand radio always want to know "the distance my set will receive." This is impossible to predict, as there are entirely too many variable features which bear on the subject. If a salesman tells you that the set he tries to sell you will receive 2,000 miles take it with a large amount of salt and tell him that you know he is "stringing you along." It is impossible to even fairly guess at the distance a receiver will function. Also do not expect to pick up more than one-third the distance in the summer time that you received in the winter. Be satisfied with local stations.

Too Much Is Bad

MANY amateur builders, when constructing sets, have a very bad habit of using too much soldering flux when making connections. Do not use too much, as it will spread and cause leakage. A little (very little) goes a long distance when the iron is properly tinned and hot.

(*Concluded from preceding page*)

other, when a piece of insulating tubing should be slipped over one of the wires.

A word about the antenna system. A great deal more care is required in the construction of a sending antenna and ground system than is necessary for an antenna and ground which is to be used for receiving only. The best type of aerial is the cage type. About eight wires, 80′ long, soldered to metal hoops about 3′ in diameter and with a cage lead-in which tapers sharply, so that the point is at the lead-in insulator, will make the most efficient sending antenna that you can erect. Keep it as far away from trees and other objects as possible, as all these things absorb some of the energy. If possible, use a counterpoise ground. Keep it well insulated from the ground, and have it extend a few feet on all sides of the antenna, directly underneath. If it is impossible for you to have a counterpoise, use buried copper plates or chicken wire, placed directly beneath the center of the antenna. If the counterpoise is used, have it perfectly horizontal, because if one portion is higher than the rest, the resistance is increased.

With this set an antenna current of one ampere is easily obtained, if a power tube and a good antenna system are used. The reliable range of the set is several hundred miles, and under very good conditions distances of 1,000 miles or more are often reached.

This set, if adopted by all the spark coil "brass pounders," would cause a tremendous reduction of QRM amongst the amateurs, as well as a reduction of interference experienced by broadcast listeners.

RADIOGRAMS

WORLD NEWS HAPPENINGS BRIEFLY PHRASED FOR OUR BUSY READERS

Closes Big Radio Deal

(C. Kadel & Herbert)

Scene at the Metropolitan Trust Co., New York City, when the syndicate headed by Edward H. Jewett, of Detroit, took control of DeForest Radio Telegraph and Telephone Co., of Jersey City, N. J., by purchase of the personal stock in the company held by Dr. Lee DeForest, radio pioneer.

At times people talk of the warfare between science and religion, but a minister in the Middle West has said: "Religion that is killed by gasoline or radio never was alive."

* * *

In order to protect workers from accidents and eye sight damages, no less than five states—New York, New Jersey, Pennsylvania, Wisconsin and Oregon—have now in force lighting codes for industrial establishments. Other states are now considering the adoption of similar codes, and it seems only a question of time when all the states will adopt such a code.

Owen D. Young, president of the General Electric Company of Schenectady, N. Y., who recently returned from abroad, visited Washington last week and gave to President Coolidge his views on conditions in Europe.

* * *

Radio enthusiasts will be particularly interested in "Zeno," which opened at the Forty-eighth Street Theatre, New York City, last Saturday night, because radio is used not only to create many of the spiritualistic illusions with which this new thriller abounds, but is also employed by the criminals in eluding the police and finally by the police themselves in capturing the gang and clearing up the mystery.

* * *

Radio will play a large part in the next Presidential campaign in Mexico. Two leading newspapers—one morning and one afternoon—have opened broadcasting stations, which are giving concerts three nights a week. Politicians are studying a plan to use these stations to broadcast the ideas of candidates. Mexico City alone has 600 receiving sets, with many more in the suburbs. Other large cities, such as Guadalajara, Monterey and Puebla, have scores of radio fans.

* * *

Dr. Charles P. Steinmetz, the electrical wizard of Schenectady, N. Y., has been indulging again in prophesy. He predicts that in another 100 years electricity will do most of our work, so that no one will have to labor over four hours a day. This would leave lots of time for "voluntary agriculture" and many forms of self-improvement and leisure. All of which leads Heywood Broun to observe in his column in the New York World: "In spite of the lack of leisure in the land, most lives are organized for sporadic expeditions to kill time. We mangle hours and whip seconds through a slaughter-house. Treat time kindly and it will do as much for you. Pat it on the head and it will arch its back and stretch. In fact, anything which can be done to keep time alive renders it a far more pleasing playmate than do all the various devices by which it may be slain."

Making One 22 1-2 Volt B Battery Serve for Detector and Amplifier

By E. C. Mallory

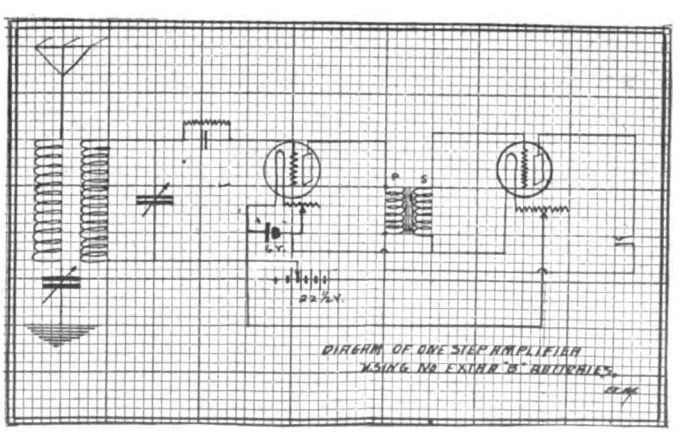
DURING the course of my daily work as radio operator aboard the S. S. "Governor Cobb," I have made a little discovery, which may not be new to some people, but strikes me as being something that I have never heard about before.

On board we use the type 106 B Marconi receiver and also a standard regenerative circuit. During my "fooling" around and changing B batteries, I happened to connect just one 22½ volt B in such a manner that when I looked the second time I saw that it would supply both the detector and amplifier.

In the diagram which I am submitting (detector and one stage non-regenerative) you will notice that there is no 45 volt B amplifier battery. The diagram is the same as the ordinary hook-up, only that the lead which generally goes to the positive of the 45 volt B battery goes back to one side of the primary of the transformer, thus eliminating the B battery.

I have used this hook-up very successfully and have surprised many when I tell them of it. Everybody is trying to figure out just why they did not discover it before, especially when the amplifier B batteries were running low.

One point that I found out that is necessary is that it is sometimes best to reverse the primary leads to the transformer to get the best results. Of course, it should be tried both ways to determine which is the best. The circuit works as well on the non-regenerative as it does on the regenerative, which is saying something. I am giving it to you so that you can tell the fans and maybe help some of them.



Showing how to use one 22½ volt B battery for both detector and amplifier.

Why I Flunked Three Times in the Radio Code Examination—And Then Passed

By One Who Did

OUT of the tens of thousands of broadcast listeners there is bound to evolve a goodly number of radio amateurs and commercial operators. When once the virus has been absorbed, the attraction of code work is irresistible. The short and long buzzes from the spark and C. W. stations seem to have a sort of romantic allurement that is less apparent in the more common voice transmission. And the joy of personally getting on the ether is far too great for adequate expression.

About five years ago I got the bug that I wanted to become a commercial operator. For a like amount of time before that I had been an amateur, or "ham." As I was self-conscious to a large degree, and furthermore, as I had irregular business hours, I had a sort of aversion to personal instruction; so I did what was the next best thing and took up a correspondence course in the subject. I took the particular course that I did because it was very widely advertised, because it had been established for a number of years, and because the staff of instructors had credentials that indicated them to be capable men. With the course I received several books, some instruction sheets and an omnigraph for learning the code.

Right here let me give my opinion of a correspondence school for learning such a subject as that of radio. In themselves, they are fine institutions (the best of them), but what a person can get out of them depends a great deal upon his own psychological characteristics. A person, in order to get the most out of a home study course, must be a "plugger." He must be perfectly contented to sit alone for long periods and study, and persistently listen to the code buzzes even before they are in any degree intelligible. He must be a person who burns with the desire to learn and not one who must have everything knocked into him with a mallet. If there is that earnest desire that will sustain persistent effort, and if the person is naturally intelligent and responsive to book learning, if his time and money is limited, and if he does not require the personal touch of a teacher, the correspondence method is to be highly recommended. Otherwise, disappointment would be avoided by taking up class work with a real live instructor.

Being very busy with other work at the time I started the course, I had very little time to spend on my studies. Getting home rather late nights, and being tired out, I found it difficult to concentrate to any extent. It required on an average of six readings to thoroughly digest the contents of a single page of the book. But there is one thing that I learned afterward, and that was that the knowledge I gained in this way did not go in one ear and out the other, but stuck fast; and much of it I remember to this day.

Being of a naturally phlegmatic disposition, the code was even harder to master. It simply would not seem to sink in. And it was especially difficult to listen for long periods to the very impersonal omnigraph, which repeated the same old thing over and over. So the result was that I succumbed to procrastination, and many nights I did not listen in at all, but simply did my theory work. Then again, I had the fault of wanting to get ahead too fast, which tempted me to increase the omnigraph speed beyond my capabilities at the time. This trick did nothing but tend to increase my disappointment at not being able to copy, and at the same time retarded my progress.

Later I tried to do some reception over a regular receiving set, with still less success than with the omnigraph, for the reason that most of the stations which I wanted to copy sent too fast, and some others too slow. That is one thing that is soon realized by a code student—that there is a too slow speed as well as one too high. Of the ten word a minute stuff, I could copy about every second letter, of the fifteen word stuff, about every third letter; and of the stuff at twenty words, only about every fourth. Still I persisted in trying to copy these speeds, instead of seven or eight on the omnigraph, which I should have done.

The theory came on pretty well; and to make it more interesting, I accepted a position as instructor in a large Y. M. C. A. radio club. There I had the surprise of my life. Those fellows could ask some of the darndest questions that existed—some that I would never think of in a lifetime. That put me on my mettle, and rather than show my ignorance, I put in some intensive study in a big library. There was nothing in the line of radio that I did not touch on; from the ether and electron theories down to the practical phase of adjusting a catwhisker. The value of this work, which was just to satisfy the "kids," was not realized until later on in my experiences. It did one good thing in that it gave me a very firm foundation for later practical work.

Once more getting the craving to have a radio license, so that I could "shove off" as an operator, I went back to intensive code practice—or, at least, what I called intensive. But, try as I might, it seemed that the harder I worked toward this end, the farther back I slid. One day a friend came to me and asked why I did not attend a certain resident school, as he had made such remarkable progress there. This was a new hope, and I grasped at it eagerly, enrolling for code practice almost immediately.

At this school there were a number of long tables at which the students sat to send and listen in, and at the end of the room was the instructor with his hand sending key, and several automatic sending machines. Under this system I was first advanced to the ten word and then to the twelve word table. But at this point my receiving ability came to a standstill, and occasionally even seemed to drop back a pace or two. I could send fairly well at a twenty word rate, but my receiving was rotten. At about this stage in their learning, the students all seemed to like to waste their time, and cut-up rather than do earnest work. So, for at least a month, I did not visibly advance one particle.

At the end of that time I had another spurt of enthusiasm, and almost overnight I found I could easily copy fifteen words. Then eighteen! This was all too good to last, and I came to another standstill. I could take down twenty or twenty-two words in my mind, but I could not get them on the paper; my hand wouldn't respond quickly enough to the mental impressions that were telegraphed to it.

So at last, giving up the idea of getting a first grade license as hopeless, I made an appointment with the inspector to try for a second grade license. I was confident that I could get this, as the required speed was only supposed to be twelve words a minute. It was only a few days before the examination, so I did a goodly bit of "cramming" both on code and theory.

The eventful day arrived, and shivering, yet perspiring, I found myself sitting by a little desk in the Radio Inspector's office at the Custom House, with pencil in hand, paper before me and a single phone over one ear. Immediately the destroyer, Worry, popped up. "There is so much noise about the room. It's getting cold. You are not used to a single receiver, and therefore you will not be

Digitized by Google

able to hear well. The omnigraph that the inspector uses will kick and jump, and you will miss many letters. You can't pass, so what's the use?" All of those things ran through my mind and gave me the cold chills. And it seemed that everyone else about me was in the same mood. There was at least a half hour of suspense before the inspector announced that everything was ready.

Then came the five minutes of torture. First a little squeak as the buzzer was adjusted, then a moment of testing the omnigraph speed, and finally the real sending for the test. The speed was about eighteen words a minute. About five words passed before I was able to make the first stroke with the pencil, then for about eight words I ran along very nicely. But at that moment the omnigraph gave a lurch and rendered a letter indistinguishable. This threw me off my track, and I missed a half dozen of the following words. For the remainder of the five minutes I got about every second word, and a few of the letters in between; but as to pass requires at least sixty consecutive letters in one string, I managed to fail, miserably. The inspector was good enough to give the same test over again for those who failed, but I was so shaky by this time that I flunked once again, and was told that I could come around at the end of a month and try it over.

At the end of the month, I tried again—and flunked flat. At the end of another month I tried again, and again failed. The third month spelled failure for me once again. Then the new law came into existence, that made it necessary for a flunkee to wait three months before being given a chance to try again.

Having all that time on my hands, I started to thinking. Possibly I was following the wrong track. Possibly I was following something that was hopeless. But whatever was the matter, I was determined to find out. And I did! The result was that I passed the test at the next trial, and almost got a first grade license instead of a second. As far as theory was concerned, I lost only three points, and this was taken off in half points at different places for being too brief.

What did I find out? It was simply that I had been wasting my energies trying to fight a something that did not exist. I was fighting against worry, fear, mental sluggishness and lack of concentrative power; when, if I had but known it, they were nothing more than imaginary beings that I had created myself. I learned that all good operators worked subconsciously, rather than consciously, and that though this power was natural in some, it could be acquired by others. I learned that a proper attitude would almost entirely eliminate all the extraneous disturbing factors and render a perfect concentration possible.

The goal I strived for was to make the radio code an integral part of my subconscious mind; so that whenever I put myself in a passive state of mind I could recognize the characters automatically. Then I was to try to gain the subconscious co-ordination between my mind and my hand. A seemingly difficult problem I had before me, but one which appeared simpler later than at first.

As a starter, I learned that by a change in diet I could quicken my speed and decrease a sluggish mental action. So, cutting out all the heavy proteins, such as meat and cheese, I filled up on fresh vegetables, fresh fruit and milk. This diet allowed considerable variety, and I thrived on it—a very noticeable difference in my health taking place within several weeks. Another thing which I cultivated was deep abdominal breathing. Also the habit of drinking two or three quarts of water daily, to keep the system flushed.

Whenever I chose to do my code practicing, I centered my mind about that and nothing else. Everything was done in a calm manner. Sitting down quietly before the set, I picked up the phones, and handled them for a few moments, thinking of nothing in particular. After putting them on my head, the set was slowly tuned until something was heard. The signals were brought in to a medium intensity, and for about five minutes at each period I sat with my mind fixed on this code jargon, but without making any definite effort to distinguish the individual letters. Occasionally it would occur to me that a certain combination represented "the," and another "and," and still another "New York"—the most usual words used. At the end of that period I would begin to copy. If it were at the right speed, I would continue for a time; but if it were too fast I would wait as before, or else try to tune in someone else.

I lived quite near a high-powered station, and I could get signals all over the room with a crystal detector. Occasionally I left the switch on for the night, and the signals would be the last things I would hear before going off to sleep and the first thing upon awaking in the morning, and many times upon awaking in the night I would hear them. This practice, though it may seem silly to the average person, did a lot of good.

Every time I sat down before a set I tried to free myself of all excitement, and obtain a perfect passive attitude. Nothing at all outside was allowed to worry. In a short time, by using this method, I became able to copy almost unconsciously, and instead of letters, words would form themselves. The result was that at the next examination I got my second grade commercial license—and the next examination, a *first*.

Quiet Hours Bring Harmony to Ether Waves

HARTFORD, CONN.—Recent radio regulations are helping to bring harmony into the ether where formerly chaos reigned, and this winter will see, doubtless, a vast improvement in receiving conditions, officers of the American Radio Relay League believe.

This view is based on reports from all of the League's Operating Department divisions, which indicate that the "quiet hours" between 8 and 10:30 P. M. advocated by the Department of Commerce are being observed faithfully.

It should be noted particularly that the department specifies local standard time for amateurs, which means that, if the local community has adopted daylight saving time, the quiet period to be observed is between 9 and 11:30 o'clock. A letter from the Bureau of Navigation comments in part as follows:

"The Bureau expects the amateurs to conscientiously adhere to these regulations * * * and when complaints are received from broadcast listeners that they are experiencing interference from code stations, which they believe to be amateurs, they will be required to furnish the name and address or the radio call letters of the station causing the disturbance.

"Where complaint is made that amateurs are causing interference after 10:30 P. M., local standard time, the parties making such complaints will be informed that the amateurs are required to observe a silent period of two and one-half hours each day to permit uninterrupted reception of the broadcast service, so far as the amateurs are concerned, and that as the amateurs are rapidly replacing their spark sets with tube transmitters and many of them using C.W., it is believed that they are contributing their share in the matter of giving relief from interference."

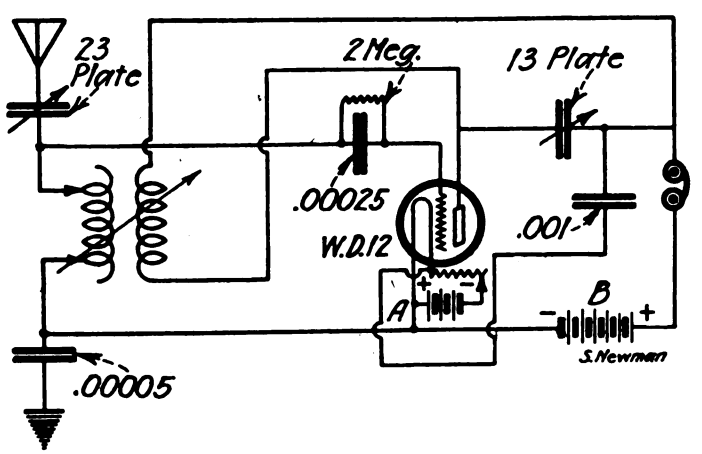
Another Improvement on Single Circuit Receivers

By A. A. Teeter

IN perusing the literature on the subject the fact is very prominent that there is a wide difference of opinion as regards the efficiency of the single and three-circuit tuner. I have made an impartial study of all circuits possible since the first of the year, and have constructed from the best of material practically every one of the popular circuits, including many of the so-called "trick" ones, and have finally come to the conclusion that the real circuit is the single or three-circuit regenerative one.

They both have their advantages and disadvantages, as we all know, but after having made exhaustive experiments with both, I must admit I have found the single circuit, properly constructed with a few additional refinements, the better thus far. However, I am using both at present.

The first question to arise in the minds of your readers will be: Is it selective and sensitive? Yes; extremely so, the most selective and sensitive I have ever



Schematic diagram of one method of improving the regular single circuit set through the use of two condensers in the plate and plate filament circuits. Greater selectivity and control of regeneration is thus possible.

operated. As an example, I can set my antenna condenser at 0 and using about 60 turns of the primary inductance, within a range of 0 to 50 on the secondary condenser dial I have tuned in WJZ, WOR, WGY, WHN, WEAF, WAAM, WBZ, KDKA, WEAS, WJAX, WFI, WOO and WIP. Sometimes, merely a fraction of a turn of the vernier of the secondary condenser will throw out WHN and bring in WGY. I do not have to sit up until midnight to get distant stations. One night during the last week of July—a hot night at that—between 8:30 and 11:00 o'clock, I tuned in the following stations, loud and clear, on detector: WOO, WIP, WFI, WDAR, WHN, WEAF, WJZ, WGY, KDKA, WBZ. On the detector and one stage audio, using phones: WJAX, WLW, WEAS, WAAF, WDAP, WOC. On the detector and two stages audio, with loud speaker: KDKA, WGY, WJAX, WWJ, WEAS, WBZ and WMAF.

Regarding the construction of this set, I have made two of them, each one using different material and parts, and the results obtained were *not* the same. Therefore, in justice to all who may want to construct this set, I will mention the manufacturer of the various parts, though I am not partial to any manufacturer's merchandise.

You will recognize this hook-up as that of the single circuit regenerator, the tickler shunted with a condenser, and the addition of two condensers so placed as to give high efficiency.

Material needed for detector unit: 1 panel, 7x18; 1 baseboard, 6x16x½; 1 vernier rheostat (Cutler-Hammer); 1 socket (Fada); 1 double circuit jack; 1 two-meg. leak, tubular R. C. A.; 1 .00025 Micadon condenser; 1 coupler (either Shamrock or Fisher No. 52); 1 13-plate vernier condenser (U. S. Tool); 1 23-plate vernier condenser (U. S. Tool); 3 switch arms and contact points; 1 .00005 Micadon condenser, 1 .001 Micadon condenser; 3 3" dials; 1 pair Brandes phones; 1 WD12 tube; 1 22½ volt Burgess battery; 1 spool of No. 16 plain copper wire (do not use bus wire); spaghetti, tin foil, binding posts.

In constructing the set shield the panel with tin foil and ground it, and note carefully the following:

Connect the rotor plates of the 23-plate condenser to the aerial.

Connect the rotor plates of the 13-plate condenser to the phone.

Run one of the leads from the secondary (rotor of variocoupler) to the stator plates of the 13-plate condenser, thence to the plate connection on socket.

Run the other lead from the secondary to the rotor plate of the 13-plate condenser thence to the phone, as previously referred to.

Connect the .001 fixed condenser between the filament (-) pole of the socket and the rotor plates of the 13-plate condenser.

In reference to the .00005 fixed condenser in the ground lead, arrange a switch whereby you can cut it out and in. It will not be needed for local reception, but has a tendency to clear up the disturbance on distant stations.

Use 22½ volts on plate of detector.

I am located on the west side of a mountain, 40 miles from New York, with a 45' aerial single copper wire between two trees 25' high. I can tune in New York and Philadelphia stations on detector alone without ground or aerial, and Schenectady without ground. This, I think, indicates in itself how sensitive the receiver is.

For amplifiers I use 201A tubes and Federal transformers. With this set I have, since June 1st, tuned in all the principal broadcast stations east of the Rockies, including such distant ones as WDAF, WIAK, WOC, WMC, WFAA, WBAP, CFCA, WSB, WDAP, WAAF and KYW.

What Not to Expect

IT is quite evident from the letters and reports of various makers of home-made sets, that they expect entirely too much from their receivers. They have read reports of records made by single tube receivers that cover 2,000 miles. Consider the fact that this is not a *steady performance*. It may be done in certain localities quite often, where there are no steel buildings, tall hills or forests, but to expect a single tube receiver to have a steady range of 2,000 miles is out of the question. Consider yourself good if you can get 900 to 1,000 miles out of it, and wear a happy contented smile.

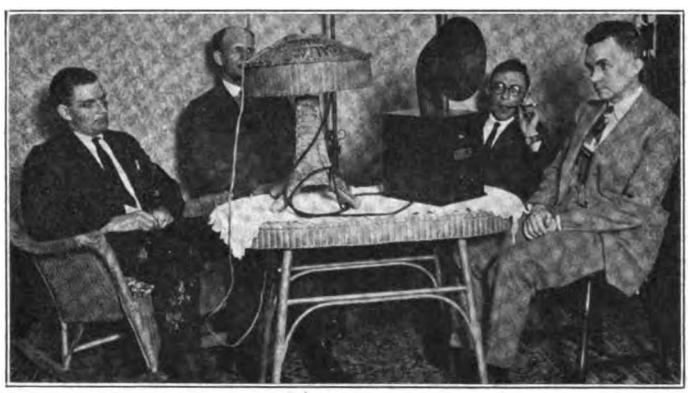
Practical Wired Wireless Demonstrated

WHEN General George O. Squier made the announcement some months ago that he had perfected a system of "carrier current telephony" whereby radio telephone signals were sent over high tension or lighting lines, quite a furore was created in radio circles, and many suppositions regarding its possibilities were made.

The North Amercan Company, one of the largest public utility corporations in America, seeing great possibilities in the system toward supplying users of commercial electric light with "wired radio" obtained permission to use the system, under the basic patents of General Squier. Its subsidiary, Wired Radio, Inc., has since then perfected the system and is putting it into active use.



(C. Kadel and Herbert)

An installation of a two-tube "Wired Radio" receiver in a house. Note the fact that it is very compact and has but one dial for adjustment. R. D. Duncan, Jr., and engineers of "Wired Radio," listening in.

Wired Radio is just what its name signifies. Instead of allowing the radio waves to emanate into space, they are confined to the limits of the lighting system. Thereby any one supplied with electric lighting, by the use of the proper apparatus, is enabled to receive radio signals anywhere in his home where there is a light socket simply by plugging the receiver into the light socket.

At the transmitting end, the system resembles the regular broadcasting station. There is a studio with its "pick-up" devices or microphones. The sound waves are carried along to the amplifiers where they are boosted up preparatory to being put into the transmitter and sent out along the wires. The transmitters being used were developed by the engineers of Wired Radio, Inc., especially for this purpose.

The receivers used to make the music audible to the people desiring the service were also specially designed. They are made to be as near fool-proof as possible. In the receivers that will be used there is just one dial and a crystal detector. A fixed crystal detector is being perfected that will eliminate that adjustment.

It is easily seen that with this system, no antenna or ground being necessary and only one dial to operate that it is indeed "simplified." At present music or broadcast programs will be sent on only one wave length, therefore no tuning will be necessary after the first adjustment.

The method to be pursued by Wired Radio, Inc., is as follows:

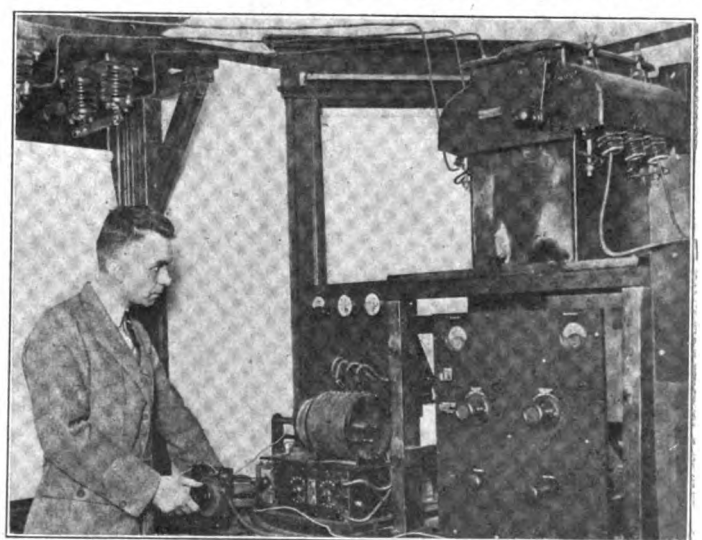
The users of electric light desiring to receive the programs that will be sent out over the Richmond Light and Railroad Companies Electric Lighting lines by Wired Radio, Inc., will be able to choose from three sets which have been standardized. The first is a crystal set, with ear phones; the second is a two-tube receiver with loud speaker, and the third a three-tube receiver with loud speaker. The crystal receiver will rent at $2.00 per month, the small loud speaker set will rent at $3.50 per month and the large set will rent for $5.00. The receivers remain the property of Wired Radio, Inc., and their use will be billed the same as the regular electric light service.

The service is installed on Staten Island, N. Y., and a demonstration of it was given to a group of press representatives on August 29, 1923.

The studio, which is at present a private house in Staten Island about one mile distant from the power house is where the programs will emanate from. On the first floor is the studio, draped with heavy hangings and having the necessary "pick-up" devices for broadcasting of piano music, talks, or orchestral selections. On the second floor are the amplifiers and transmitters, as well as a United Press Station where United Press reports will be received direct, and all the latest news will be given from the studio. The transmitter is coupled with the high tension lines that supply Staten Island, and radiate the energy directly over these lines. On the top floor is a loop receiver comprising four stages of radio-frequency (one of tuned radio, three of broadly tuned or transformer coupled) detector and power amplifier, operated on a two-foot loop. This receiver will also be used to pick up the programs sent out at the present time by the broadcasters, amplifying it, and re-transmitting it over their wired radio system.

It will only be necessary for the subscribers of the Wired Radio, Inc., to plug their sets into the sockets and turn on the light in order to receive the programs.

The wired radio program will consist of complete news service supplied by the United Press. Reports of all sporting events, time service, fashion, health food, housekeeping, gardening talks, stories, reviews, lectures, all kinds of music and reports of various functions. Its programs will start at 7:00 in the morning, and continue until 11:00 at night. It is expected to provide as soon as a survey is made of the programs that are desired two or three different types of programs on different wave lengths.



(C. Kadel and Herbert)

R. D. Duncan, Jr., engineer, adjusting the wired wireless transmitter. Note that it is directly coupled to the 2,300 volt high tension transformers through the switching arrangement on the window over his head.

The personnel of Wired Radio, Inc., is: C. W. Hough, president; R. D. Duncan, Jr., chief radio engineer; James T. Kolbert, editor news service. Wired Radio Service Co.: J. A. Mears, president.

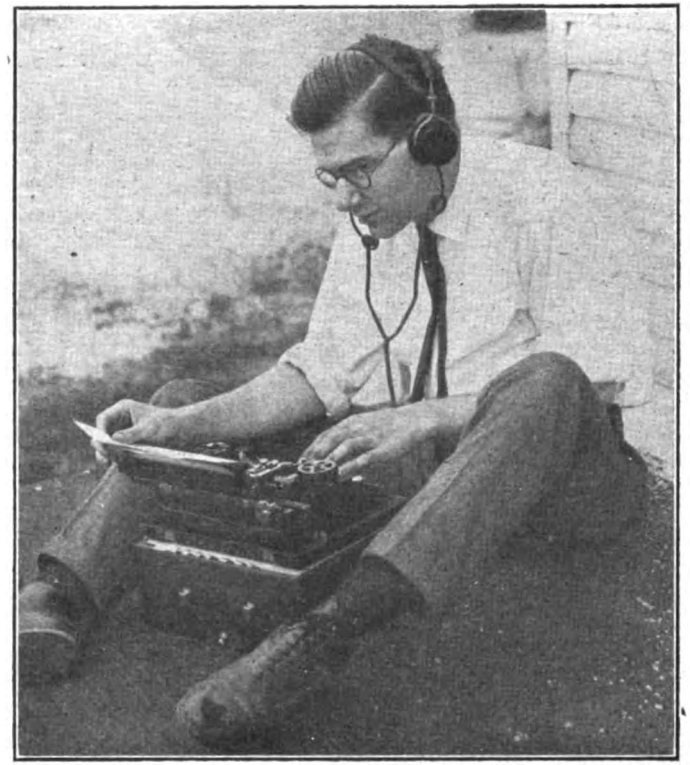
Radio News Pictures Arranged Poster-wise

(C. Kadel and Herbert)

Here is one of the scenes that the radio audience recently "heard" from the drama "Thumbs Down" broadcast from Station WOR, Newark, N. J. The play was summarized before beginning, as to settings, and the cast, and then was broadcast in the manner shown. Music was played between acts, and the ringing of a gong warned the folks of the "rise of the curtain." The illustration shows John Marston, Sue MacMananamy and Howard Lang, the principals, acting one of the "tense" scenes before the Mic.

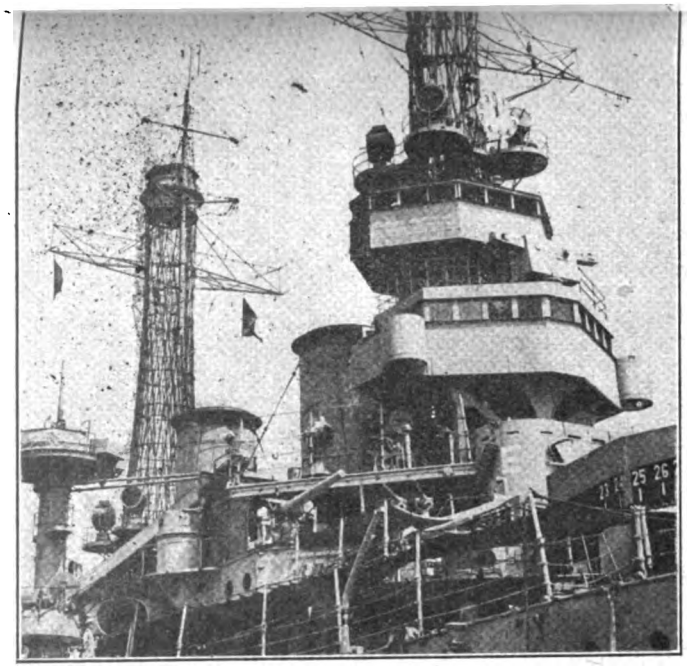
Jud Landon, Apostle of the Great Outdoors, who recently gave a series of addresses at WGY, Schenectady, N. Y. He has given talks on fishing and hunting and has accumulated quite a number of followers who like to listen to him, even though they cannot follow his methods of "smoking out a bear" or "fighting a giant tuna fish." The illustration shows "Jud" in front of the new "glow-discharge" microphone.

(C. Underwood and Underwood)



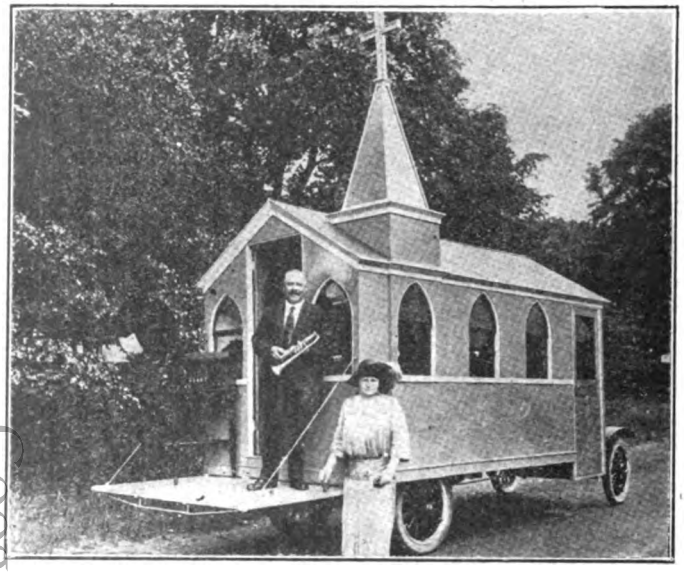
Kenneth M. Swezey, the writer for RADIO WORLD and who is a favorite with many fans, is here shown "picking ideas" out of the ether while sitting on the roof outside his room. With his trusty Corona and radio set, he can get them as they "come through" and keep right on thinking up new ones for the fans to play with. This is, by the way, a good way of testing out your speed in copying. If you can type code messages at 30 per minute as they are sent, you need have no fears about getting a "1st Commercial."

Digitized by Google



(C. Kadel and Herbert)

You fans who think you have elaborate antenna systems take a peep at the antennae of the U. S. S. "Wyoming," one of the latest battle ships. Four antenna systems can be used either separately or together.



(C. Gilliams)

A curious sight these days in and around staid Boston is the "Radio Church on Wheels." It is a replica of a church, mounted on the chassis of a car. Sermons and sacred music are received over the radio and broadcast to the open air crowds. Therefore, even the ones who claim they "live too far from the church" cannot get away from this ardent evangelist and his wife.

brother rig up a crystal set that she used on a loop aerial, and parades around the park near 2LO and hears the programs as they are broadcast.

(C. Atlantic Foto Service)

An idea for radio fans who want a good small loud speaker. An Atlantic City amateur discovered that an ordinary conch shell when properly attached would make an excellent loud speaker. A shell of that sort having absolutely perfect acoustics gives a volume of sound that is really surprising. Compare the entire loud speaker with the plug alongside of it.

(C. P and A Photos)

Mrs. H. A. Leslie, of Los Angeles, who claims that she was cured of a serious illness, by hearing Aimee Semple MacPherson, noted woman Evangelist, over the radio, while practically waiting for death. The illustration shows Mrs. Leslie listening in on the set she says was responsible for her marvelous cure.

(C. Kadel and Herbert)

Judge Ben B. Lindsay, of Denver, examining the new radio set he has just bought. It is the RC receiver with power amplifier and loud speaker. If it was not for the fact that there is no jack in the detector panel, and no battery connections to the loud speaker, we might tell you that he was listening to WEAF, but we cannot do anything so obviously wrong. Anyway, it is enough to state that Judge Lindsay is a "reg'lar fan."

(C. P and A Photos)

Radio detachment of the 69th Regiment in camp at Peekskill, N. Y., setting up their portable field set for practice. The set used is a combination receiver and tube transmitter, being operated by means of storage batteries, which, while not considered portable in every sense of the word by average fans who have to lug them to the battery shop every two weeks, are portable for this type of work and furnish steadier current than a hand driven generator.

Four girls crabbing with the aid of radio. They are using a regenerative set, with two wires in the water for antenna and ground. The one wire used for an antenna is well insulated and the open end sealed with wax to prevent contact with the water. The ground wire is bare and both are trailed in the water. Makes a good antenna, too. And by-te-bye, although you cannot see it in the picture, the young lady wtih the earphones has just landed a crab in her net.

RADIO PRIMER
For the New Army of Radio Beginners

LOCATION OF TROUBLES IN A RECEIVER: After a fan has constructed a receiver or even bought one, there is no guarantee that little minor troubles will not occur. If he is a beginner he will fuss around and probably spoil the receiver, or cause trouble, where none existed. Therefore by knowing just where to look for the minor troubles he can obviate the necessity of calling in "expert" advice.

The commonest trouble is probably due to faulty connections. For some unknown cause, wires will come loose without the least apparent reason. The first place to look for trouble in that line is in the B battery circuit. Examine your connections to the set, and see that all the connections from the batteries are tight, and the wires scraped clean. Examine your antenna and ground connections and see that they are all tight.

If the set has been carefully soldered, and the mechanism has not been fooled with, there is no use to look at the connections inside unless lugs have been used to fasten the wires under the binding posts. If such is the case, light the tubes and very carefully joggle each lead. Do not feel too strong when doing this, and do not use any metallic instrument such as a screwdriver. Rather use a pencil or your fingers. If there is a loose connection it will immediately show by various clicks and the connection should be tightened.

Should all the connections be found tight, examine the tube by taking it out of the socket and seeing that all the lugs are clean, and making positive contact with the socket.

Probably one of the commonest causes of faulty operation is the use of poor B batteries. A B battery can be in fine condition one night and will rapidly fall in value until it will probably just operate or operate spasmodically. Therefore test your batteries by means of touching them quickly to a voltmeter. Do not hold the voltmeter across the battery as it will short circuit and be no good altogether.

Next examine your plug and phone cords. The tinsel inside the cord is fragile, and ofttimes breaks off inside the cord, the outside not showing the break. Therefore examine your plug and jack, by connecting a weak dry cell across it. If no response is given to the connection, remove the tips from the plug, and connect it across the battery, and then carefully "feel out" the cord by holding it in the hands and wiggling the cord an inch at a time looking for the break.

Should you prove unsuccessful in finding the trouble after the above take the phones and battery, remove the tubes from the socket, and individually test out each connection by means of the battery and phones, taking particular care with the inductances and transformers, always testing out on both sides of the condensers, and also across the condensers, to determine if any of them are blown or shorted. A condenser when the phones are thrown across with the battery should not give any response when the connection is made and broken. If it does the condenser is shorted and should be taken out.

A little care taken in the testing instead of madly searching around with fervid brow and beating heart, and by reasoning everything out before "flying off the handle" and wrecking the set without any cause, will ofttimes help more than calling in one of your friends and having him wreck the set for you. The old saying of the miner who was packing "grub" up the mountainside should prove of value to everyone in this case—"Slow and steady, does it, son."

The Radio Woman

FRIEDA, the General of the Kitchen, otherwise known as the cook, had been looking askance at radio for some months. "Dot aind't right—Gott nefer made beobles to make music in the air, and I woun't listen from it," used to be her daily speech, as she would hurry to the kitchen and slam the door. She is a really good cook, so we decided to humor her and turn the set off when she was feeling particularly bad about the matter. The inevitable change has come, however, and now Frieda wants us to put "one of dos radios" where she may hear it. The reason for the sudden change is that her cousin, who has been out west for years, recently returned and told her that he is a research engineer in one of the western radio plants. He had quite a rumpus with her, but he told her that it was not "defil's magic," and even went to the trouble to take her down to the city on her day off and let her see how it was done.

* * *

Isn't it queer what notions some people take into their heads? F. H., who is now considered quite an expert on radio troubles, was called in by a friend living down the block to find some trouble on the receiver that he had just made, and which wouldn't tune a bit. As a matter of fact, every station in the world seemed to be mixed up in one grand jumble, with code and everything.

"Well," commented Friend Husband afterwards, "outside of the fact that he didn't use the coils prescribed, but had a bright notion that honeycomb coils used in place of the special bank wound and other coils would be better, hearing that they were more efficient, and also using two condensers where they were not supposed to be, and using any kind of wire and wiring it up exceedingly messy, with too much paste and tons of solder, he had it worked out very well. It's a wonder to me that it even peeped. If some of these amateur constructors would read the articles thoroughly, and pay less attention to their 'radio expert' friends, who have probably built one home-made set and get all their knowledge from having bright thoughts on the subject, I think that everybody who attempts the building of a set would be helped immeasurably. I think I'm going to start a school for radio men to teach them the art of soldering one wire to another. I think that a three-year-old child could have done as messy a job as that grown man did, but I am not sure."

* * *

Friend Husband, through his talking and talking and talking radio, finally persuaded his club mate and golf friend to get a set at one of the big stores. Accordingly, Billie purchased the set, hooked up a nice antenna according to directions, connected the batteries very nicely and then started in to listen. He is not a "dumb dora" by any means, having played around with tools and wires—but not radio—for quite some time, so that far he was successful.

About a quarter of eleven that evening, the phone bell rang, right in the midst of our Philharmonic Symphony, and Billie told F. H. that he had connected everything right, was perfectly sure he had, but couldn't get a sound out of it. Friend Husband groaned something about "pests" and put on his coat.

He was gone about 20 minutes when back he came, with a smile all over his face. "That wise man goes and hooks up his set and then leaves the tubes in their boxes lying on the table upstairs and tries for two hours and a half to hear something, and cursing the day that I ever pursuaded him to buy it!"

Answers to Readers

Where can I obtain a circuit diagram using the following apparatus: WD11 tube, variocoupler, variable vernier condenser, switch? How do you place the condenser in series with the variocoupler?—L. B. Reid, 605 Van Nuys Bldg., Los Angeles, Calif.

A very fine article using the apparatus you mention, and giving very excellent plans for the building of the receiving and detector unit appeared on page four of RADIO WORLD April 14, 1923. All details are explained in that article which is well illustrated.

* * *

Will you kindly give me the address of Bob Kalmus, whose article appeared in a recent issue?—John Keiler, Los Angeles, California.

The address is c/o H. Baran Co., 2325 Broadway, New York City.

* * *

I have been told by friends that I should renew the cartridge in my lightning protector after every storm. I am located in such a position that I cannot very well do so without buying a whole box of the renewal cartridges. How can I eliminate the necessity for this?—Jacob Strausman, Ellenville, N. Y.

You have been misinformed. You do not have to renew the cartridge after a storm unless the antenna of your set is actually hit. This is a very faint possibility, so you need not worry about it.

* * *

Does the ground wire have anything to do with the correct operation of the receiver? My set tunes very broadly, being able to hear WJZ while trying to listen to WEAF or WOR. I use a loose coupler, crystal detector, phones and condenser. My antenna is 100 feet long, and my ground 45 feet from my set.—Alfred Kulick, New York.

Your ground lead should be as short as possible to make it. It is entirely too long. You will not be able to get sharp tuning on a crystal set, as no crystal set is capable of tuning out one station completely when its wave length is so near to that of another as the stations you mention.

* * *

Please inform me as to the effective wave length range of the spiderweb coils described by Arthur S. Gordon in RADIO WORLD Feb. 10, 1923.—Harry Vetter, 10807 91st Ave., Richmond Hill, N. Y.

With an antenna 100-150 feet long, these coils will respond to waves up to 600 meters.

* * *

I am contemplating the construction of a three tube set and have been seriously considering the inverse reflex described in RADIO WORLD by W. S. Thompson. Have also heard a great deal of the three tube neutrodyne and would like to have your opinion of which would give the best signals as to distance and volume where an outside antenna is absolutely out of the question. Will the duplex eliminate locals a little over a mile away? The single tube reflex that I am at present working does this, as well as several others I have constructed. The circuit therefore must be able to accomplish sharp tuning in order to be satisfactory. —Geo. P. Stamm, 1011 N. Wahsatch, Colorado Springs, Colo.

Both circuits you mention are excellent circuits. However, as between the two, the neutrodyne is probably capable of the best tuning as all reflex circuits using more than one tube are generally a bit broad in tuning. You can make no mistake in constructing the three tube neutrodyne, if you are careful to use the best parts and follow directions. When used with one additional stage of audio-frequency it is a wonderful "loud speaker" circuit, is clear and no distortion is possible. Suggest you write to the manufacturers for circulars and matter pertaining to the home construction of the circuit.

Will my detector and two-stage set (Atwater Kent parts) operate a loud speaker on WD-11 Tubes?—John Salbiston, Jr., Bayshore, N. Y.

You should be able to get sufficient volume from the set you mention to operate a loud speaker very nicely, depending, of course, upon the surrounding conditions. If you are in a "dead spot" you will not be able to.

* * *

In RADIO WORLD, August 4, 1923, you published a circuit by A. D. Turnbull. How many plates should the variable condenser .0005 mfd. have? From what part of the variometer is the third tap taken? How should I place the condenser on the panel in regard to inductive relation with the variometer?—Harvey Johnson, 47 Layton St., San Francisco, Calif.

The condenser mentioned should be 23 plates if of the rotary type. If the book type, you will have to get one which has that particular capacity. The third tap is taken from the wire that connects the rotor to the stator. In variometer construction, they generally make the rod that is used as the bearing act as the connector. Trace the connections and find out. You cannot place a capacitance in inductive relation to an inductance. This expression, when used, signifies placing two inductances together in such a manner that a current in one will "induce" a like current in the other, and therefore transfer part of the energy into the second coil. You cannot do this between a condenser and an inductance.

* * *

I am using a WD-12 tube on my receiver. Will using a two volt cell from a storage battery hurt the tube?—Carl Zuspan, 505 Watson Bldg., Fairmont, West Va.

You can use a two volt storage cell for the purpose you mention, if care is taken not to turn the rheostat all the way on. Suggest that you place an additional resistance in the filament circuit to prevent this happening by accident. One of the 25 ohm resistances placed in series with your regulation filament rheostat, and the slider moved down to the proper place will suffice, and act as a safeguard against burning out your filament.

* * *

Have you ever described the construction of a voltmeter? If so, in what issue?—Claude Schaffner, 67 Woodlawn Street, New Haven, Conn.

We have never described the construction of the apparatus you mention. Apparatus of this type cannot be made by the average amateur constructor because of the extremely fine work necessary. You can purchase one much cheaper than you could construct it. There are several good makes at a reasonable price on the market.

* * *

I have constructed a two-stage tuned radio-frequency receiver, two coils 3½" in diameter, 5" long, wound with 100 turns apiece of No. 22 DCC wire and tapped every 20 turns. They are shunted with .001 condensers. I have had good success with it, but notice that condenser 2 (that in the second stage) and the tapped coil have to be tuned higher than the first stage. Is this right? If not, how can I remedy it?—L. F. Jacobson, New York City.

The fact that you have to tune your condenser on the second stage higher than the first stage is correct. That is to make up for the amount of wire used in the first stage. You should not have to tune your coil higher, however, as there should not be such a great change as that. Try tuning your condenser higher and using the same value of inductance. As a general rule, the first condenser should read from 10 to 12° lower than the second.

MAGNAVOX
Radio Products

R3 Magnavox Radio The Reproducer Supreme

Make Your Receiving Set Complete

The efficiency of the Magnavox Reproducer is due to its principle of construction.

Only the Magnavox (electro-dynamic) reproducer can re-create broadcasted programs according to their original *pitch, quality* and *volume.*

Without Magnavox equipment, no Radio receiving set is complete.

Magnavox R3 Reproducer and 2 stage Power Amplifier . . . $90.00

R2 Magnavox Reproducer with 18-inch curvex horn: the utmost in amplifying power; requires only .6 of an ampere for the field $60.00

R3 Magnavox Reproducer with 14-inch curvex horn: ideal for homes, offices, etc. . . . $35.00

Model C Magnavox Power Amplifier insures getting the largest possible power input for your Magnavox Reproducer.

AC-2-C, 2-stage, $55.00
AC-3-C, 3-stage, $75.00

Magnavox Radio products can be had of good dealers everywhere. Write for copy of our new booklet.

Latest Radio Patents

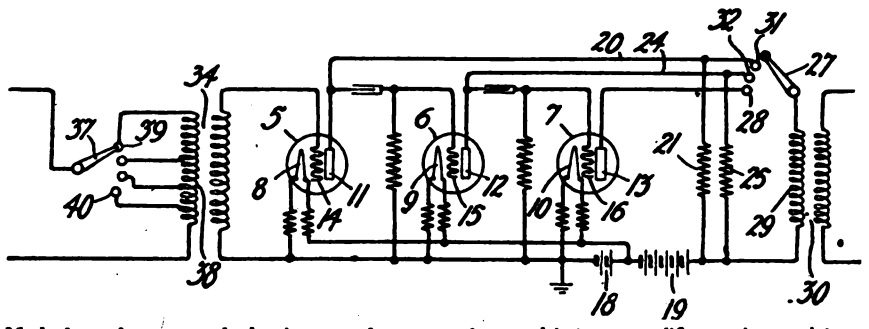
Multistage Amplifier Circuits

No. 1,459,419: Patented June 19, 1923. Patentee: E. O. Scriven, New York City.

This invention relates to multi-stage amplifier circuits and more particularly it relates to vacuum tube circuits wherein a plurality of repeaters or amplifiers are employed to amplify signals impressed thereon from an incoming line.

One of the objects of this invention is to provide a means for regulating the degree of amplification of a multi-stage amplifier set for signals impressed thereon.

As is well known in the art, weak currents or signals may be amplified to any desired degree by impressing them on a plurality of vacuum tube amplifiers arranged to work into each other by suitable circuit connections. In employing such a multi-stage amplifier set for amplifying weak currents, it is frequently found undesirable to use the total amplification of the set before impressing the amplified currents on the outgoing line or the receiving instrument, since the degree of amplification desired for each particular case will depend largely upon the strength of the incoming currents and on the electrical conditions in the output circuit into which the amplifiers work. It is also frequently desirable to cut down the degree of amplification to prevent overloading the last stages.



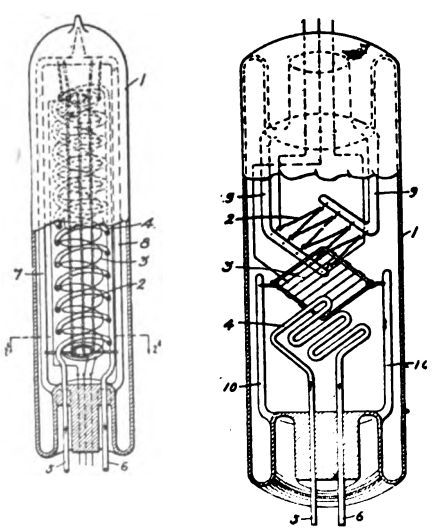
Method used to control the input and output of a multi-stage amplifier, using resistance coupling between the second and third stages, and switches to vary both the input value as well as the number of stages feeding into the output transformer.

In accordance with this invention, a single switching means is employed to cut in or out one or more of the plurality of the amplifiers so as to regulate the amount of amplification for any given case. An additional switch is also provided for regulating the strength of the currents impressed on the first tube so that by operating both switches any desired degree of amplification from the set may be obtained.

Electron Discharging Device

No. 1,459,417: Patented June 19, 1923. Patentee: Paul Schwerin, New York City.

This invention relates to electron discharge devices and especially to vacuum tubes of the audion type, and has as an object a device of the above character which has a very large power capacity.



Two methods of construction to be used in making vacuum tubes designed for transmitting or carrying excessive amounts of plate current. Elements are arranged to allow quick cooling preventing excessive heating of active elements.

In electron discharge devices of the audion type, two or more elements are used, one of the elements being a cathode or a source of electrons. Another element is the anode or collector of electrons. Under the action of a strong electrical field, the electrons from the cathode travel towards the anode, and acquire a high velocity. As a result of the electronic bombardment to which it is thus subjected, the anode becomes heated. This fact limits the power input, since excessive heating of the anode drives off the occluded gas, or may even melt the anode, destroying the device.

In this invention then, the purpose is to so construct and arrange the anode that it will be able to dissipate a very large quantity of heat. Such an arrangement will make vacuum tubes of this type largely independent of the heating factor, which heretofore has been a serious limitation to their efficiency. This result has been obtained by having a circulating medium in contact with one surface of the anode element to act as a cooling agent, and of the various agents which may be used, it has been found that water or oil is particularly suitable. This cooling of the anode, as herein described, has made possible a manifold increase in the amount of power which the audion tube can handle.

* * *

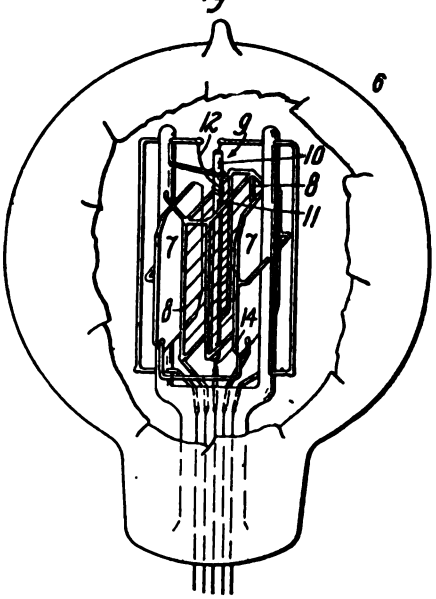
Thermionic Translating Device

No. 1,459,412: Patented June 19, 1923. Patentee: A. McL. Nicholson, New York City.

This invention relates to thermionic translating devices and more particularly to a form of cathode element for use in such devices, and its object is to produce a large energy output therefrom.

One way of increasing the energy output of a thermionic translating device, such, for example, as an audion, is to increase the active area of its cathode member. Where the cathode is in the form of a filament and is heated by a flow of current therethrough, the two ends of the filament will be at different potentials by virtue of this current flow and the resistance of the filament. When, as is customarily the case, the anode or plate element is made positive with respect to the filament by means of some external electromotive force, it is seen that there will be a greater difference of potential between the negative end of the filament and the anode, than between the positive end of the filament and the anode. There is, within certain limits, a direct relation between the output of an audion and the potential applied between the anode and cathode. It follows that other parts of the filament being at a higher potential than the negative terminal with respect to the anode, will not be working at maximum efficiency, the greatest inefficiency occurring at the positive end of the filament In other words, the space current between the anode and the filament will be unsymmetrically distributed. While this unsymmetrical distribution is not of great importance where short filaments are used, it becomes of serious importance when the length of the filament is increased to give a greater active area for the purpose of increasing the energy output of the tube.

Fig. 1



Arrangement of elements in a newly designed vacuum tube which overcomes several difficulties now present. The arrangement of the heated filament and its position with regard to the other elements is considered with regard to the space current flowing between the filament and anode.

This invention provides a thermionically active cathode which, while affording a large active area, will be devoid of the property of presenting a drop of potential between its terminals. It is in fact an equipotential cathode, that is, a cathode, all parts of whose active surface can be maintained at the same potential. Thus, an even distribution of space current over the cathode surface is permitted, and the cathode as a whole may be worked at its maximum efficiency. This result is obtained by divorcing the heating agent from that which produces the thermionic activity.

Some Interesting Radio History

IN the early days of radio, following the splendid achievement of Marconi in transmitting the letter S across the Atlantic, scientists and engineers in this country and England believed that reliable long distance transmission and reception could be obtained by increasing the power on the antenna and by building higher antenna masts. As much as one hundred kilowatts were used on spark sets and the masts were sometimes 500 feet high.

J. T. H. Dempster, an engineer in the research laboratory of the General Electric Company at Schenectady, N. Y., and a pioneer in the field of radio, explains that the American amateurs are today communicating with English amateurs with 1,000 times less power than was used with indifferent results twenty years ago. "Insensitive receiving equipment," says Mr. Dempster, "was the cause of uncertain reception and it was not until the vacuum tube came into its own that rapid progress was made."

Back in 1904, a few years after Marconi startled the scientific world with his experiment that promised to revolutionize long distance communication, the General Electric Company engineers were actively interested in the new art and they, like others, tried for a long time to offset the shortcomings of receiving apparatus by boosting the power at the transmitting end. R. A. Fessenden, formerly a professor at the University of Pittsburgh and then head of the National Electric Signalling Company, was engaged to install transmitting and receiving equipment at the Schenectady, N. Y., and Lynn, Mass., plants of the General Electric Company with the expectation that this method of communication would replace the telephone and telegraph lines.

A. A. Isbell, now Pacific coast manager of the Radio Corporation of America, was placed in charge of the installation by Mr. Fessenden. A spark transmitter of the straight gap type was built. In order to keep the gap from arcing it was necessary to blow air across it at about 100 pounds pressure. The power was supplied by a 20 KW transformer charging a condenser composed of steel plates, separated by glass plates, all immersed in oil in a steel tank. A special relay breaking a very large current in the primary circuit was designed by Mr. Dempster, in co-operation with Mr. Isbell. In operation air was blown across the carbon contacts of the relay. Because of the high potential in the antenna it was possible to draw sparks from any insulated conductor within 100 yards of the masts. The antenna mast was 180 feet high and 96 amperes were used in transmission.

The receiving apparatus consisted of the famous Fessenden liquid barretter or, in better known terms, the electrolytic detector, which was used in connection with the Fessenden interference preventer circuit. The electrolytic detector consisted of a platinum wire coated with silver. This was known as Wollaston wire. The silver coating gave mechanical strength to the wire which was less than ten thousandths of an inch in diameter. The nitric acid in a platinum cup into which the wire dipped formed the electrolyte. The platinum cup was the other pole of the cell.

The electrolytic detector was a marked advance over the Marconi coherer but it was still much less sensitive than the crystal detectors now in use. Static frequently burned the point from the platinum wire temporarily destroying the use of the detector.

With this equipment sporadic communication was established between the two plants of the company during the cold months but reception was very uncertain in the summer. In efforts to improve transmission more power was used without improving reception. The test signal used by the operator in the two cities was the letter D—a long dash and two shorts—repeated hour after hour at a stretch. This became so tiresome that Mr. Dempster built a motor driven transmitter set for Schenectady and the machine relieved the tedious work of the operators.

The headphones adopted were especially made according to the navy standard and they were wound for the first time with enameled wire. These phones were about one-twenty-fifth as sensitive as the cheapest headphones on the market today.

In the early days of radio the signal acted directly on the receiving apparatus, whereas today, by means of circuits and B batteries, the signal is magnified from one to 25,000,000 times, the signal acting as a valve to regulate the B battery current. Back in the old days signals were occasionally received when fifty kilowatts were impressed on the antenna, using 180 foot masts. Today, an operator in Lynn with a three-bulb receiving set can get Schenectady signals 1,000 times stronger than was possible in 1903 and that from a transmitter using but five watts and a mast fifty feet high.

At the same time experiments were being carried on in Schenectady and Lynn, Prof. Fessenden was operating two very high powered stations using 100 kilowatts with 480 foot steel masts and umbrella antenna. One of these stations was located at Brant Rock, near Plymouth, Mass., and the other was at Machrihanish, Scotland.

Twelfth Edition of a Popular Radio Text Book

"WIRELESS Course in Twenty Lessons," by S. Gernsback, A. Lescaboura and H. W. Secor. 264 pp., many diagrams and illustrations. Experimenter Publishing Co., New York City. Price $2.00 net.

This is the twelfth edition of a standard radio textbook which has proved its popularity since its initial appearance in 1911. Many revolutionary changes have taken place in radio since this book was born but the authors have kept track of the progress made and the present edition has been completely rewritten in greatly enlarged form. The twenty lessons form a comprehensive course of instruction in radio and should appeal to the new and constantly growing army of radio enthusiasts.

New Signal Corps Pamphlet on Radio

A PUBLICATION giving an introduction to the subject of line radio communication has just been prepared under the direction of the Chief Signal Officer of the Army in co-operation with the Bureau of Standards. The pamphlet gives an explanation of how messages are carried to distant points by radio frequency currents directed over ordinary telephone lines or power wires. The fundamental principles of radio and its relation to line radio telegraphy and telephony are discussed. Copies of the work, known as Signal Corps Radio Communication, Pamphlet No. 41, and entitled "Introduction to Line Radio Communication," can be obtained from the Superintendent of Documents, Government Printing Office, Washington, D. C., at ten cents per copy.

National Radio Week Will Be from Nov. 25 to Dec. 1

THE National Radio Week Executive Committee of the Radio Trade Association has decided to hold National Radio Week this year from November 25 to December 1. Details may be secured from L. A. Nixon, secretary of the Radio Trade Association, 1133 Broadway, New York City.

Pierre Boucheron, manager of the publicity department of the Radio Corporation of America, will head a special committee of publicity men who will use their combined efforts to forward the interests of this important event.

H. Gernsback, editor of RADIO NEWS, as chairman of the publicity committee of the Radio Trade Association, will urge the co-operation of the trade at large in making National Radio Week a success.

A special committee of the leading directors of broadcasting stations is now working out a type of program for the week which will permit every broadcasting station in the country to co-operate in making their programs especially appropriate to the event and attractive to thousands who now do not own receiving sets.

National Radio Week will mark the opening of the buying season for the holiday trade. Every radio firm who takes advantage of this opportune publicity should reap great profits.

Any one with ideas to make National Radio Week even more successful is invited to address the secretary, Mr. Nixon, or any member of the executive committee which is composed as follows:

F. Clifford Estey, National Chelsea Radio Corp., Boston, Mass.

Arthur H. Lynch, RADIO BROADCAST, Garden City, N. Y.

Arthur H. Halloran, publisher, RADIO, San Francisco, Calif.

Theordore R. Gerken, The Marshall-Gerken Company, Toledo, Ohio.

Benjamin Gross, Radio Stores Corp., New Yok City.

Roland Burke Hennessy, publisher, RADIO WORLD, New York City.

Major J. Andrew White, WIRELESS AGE, New York City.

United Cigar Stores Trying Out Radio Sales

THE United Cigar Stores Company last week began an interesting sales experiment in three of its New York City stores.

Standard radio sets and parts were placed on sale in charge of experienced salesmen. The object is to determine whether the public will buy radio goods through a cigar store.

No cut price goods of any kind will be carried and only standard sets and material will be stocked. Competent advice and service will be given to all purchasers.

If the experiment proves successful, it should afford a tremendous outlet for radio goods of every description, as the United Cigar Stores Company is one of the largest and most profitable retail selling organizations in the world.

The radio industry will await with great interest the verdict of the public and the decision of the United Cigar Stores on this interesting and very important experiment.

A Good Thing Worth Repeating

Sol Kahan keeps a prosperous news, stationery and cigar store at 305 North Avenue, New Rochelle, N. Y. He sells a great many RADIO WORLDS in the course of a month. We noticed recently that Mr. Kahan had two unsold copies of RADIO WORLD of August 11 on his stand. A few days later he was asked if these copies had been returned to the American News Company, and he replied, "No, I keep my back numbers of RADIO WORLD in stock and sell them out, sometimes quite a while after their dates. I find there is a good demand for back numbers. In this way I always sell out my full supply of RADIO WORLDS."

Here is a tip worth following by other newsdealers.

Coming Events

AMERICAN RADIO EXPOSITION, Grand Central Palace, New York City, October 6 to 13, 1923. J. C. Johnson, general manager.

ANNUAL HOME AND CITY BEAUTIFUL EXPOSITION, featuring radio exhibits, Atlantic City, N. J., June 16 to September 8, 1923.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS, Pacific Coast convention, Del Monte, Cal., Oct. 2-5. F. L. Hutchinson, 33 West 39th St., New York.

AMERICAN RADIO RELAY LEAGUE, second national convention, Chicago, Ill., September 12-15, 1923. Chicago Radio Traffic Association, 959 The Rookery, Chicago, Ill.

Radio Literature Wanted

Manufacturers of and dealers in radio apparatus and accessories are notified that literature and catalogues describing their products have been requested, through the Service Editor of RADIO WORLD, by the following:

B. A. Harden, Le Roy, Minn.
A. J. Benkett, 966 South State St., Syracuse, N. Y.
Nate W. Hunter, 641 Palmwood Ave., Toledo, Ohio.
Leonard Klarnet, 165 Beach 117th St., Rockaway Park, N. Y.
Charles Woodhams, 808 Center St., Chicago, Ill.
Summers T. Carter, 1507 Pechin Ave., Roanoke, Va. (Dealer.)
John Elker, 542 South Third Ave., Kankakee, Ill. (Builds sets.)
M. G. Stevens, Kendall, N. Y. (Dealer interested in power amplifiers.)
C. C. Lewis, 49 Main St., Fairchance, Pa.
Virgil R. Harbert, Lumberfort, W. Va. (Builds sets.)
R. F. Siggelkow, 316 East Prairie St., Lanark, Ill. (Builds and remodels sets. Interested in parts.)
Wm. R. Holloway, 1333 Locust St., Norristown, Pa.
James F. Clark, 142 West 82d St., New York City. (Interested in up-to-date variocouplers and variometers.)
Sam Chernetzley, 593 Stone Ave., Brooklyn, N. Y. (Wants to buy a set.)
H. G. Bergman, 103 Lake Ave., Mariners Harbor, N. Y.
Manley G. McKinley, Mendota, Mo. (Retailer.)
F. E. Whitcomb, Jr., 3838-a Blaine Ave., St. Louis, Mo.
W. B. Shanafelt, Sigourney, Iowa.
W. V. Trott, 9 Barker Ave., Hamilton, Ontario, Canada.
Gail Bartlett, Atlanta, Macon County, Missouri.
Donab Fregoll, 16 Washington St., Central Falls, R. I.
Max Robbins, 296 Georgia Ave., Brooklyn, N. Y. (Builds sets.)
William Devereux, 1371 Green Ave., Brooklyn, N. Y.
Michael E. Kondrat, 94 Exchange St., New Haven, Conn.
Anthony C. Budenkaye, 45 First West St., East Plymouth, Pa.
Guy M. Chase, 677 Garden St., Elizabeth, N. J.
A. D. Coleman, Farragut, Iowa.
John Daly, 45 Enterprise St., Adams, Mass.
Joaquin Sangenis, Perla No. 15 (Gracia), Barcelona, Spain.
Arthur Cauffield, 908 Lafayette St., Niles, Ohio.
Arthur G. Davis, 624 Vine St., Camden, N. J.
Sam Barclay, 1812 Washington St., Fort Worth, Texas.
George T. Vallee, 17 Commerce St., Norwalk, Conn.
George Broadbent, 18 Cross St., Mifflintown, Pa. (Distributor.)
A. Abbati, 319 East 152nd St., New York City. (About to start a retail radio business.)
H. B. Hassinger, 654 12th St., Newark, N. J.
August Nardore, 7001 Tenth Ave., Brooklyn, N. Y.

Putting Radio on the Map of the World

P. C. KULLMAN & CO., 110 Nassau Street, New York City, specialists in wireless securities, are continuing their efforts to "put radio on the map of the world" and have issued the seventh of a series of circular letters addressed to government officials in charge of wireless in 112 foreign countries. The firm has secured the services of E. Walker Sawyer, I.R.E., who will answer any technical or commercial questions addressed to him as above, in English, French, Spanish, Italian, German or Portugese. Replies will be made by mail, cable or radio as the inquirer directs.

National Radio Chamber of Commerce Will Demonstrate Radio to Farmers

THE National Radio Chamber of Commerce, 165 Broadway, New York City, assisted by the manufacturers and distributors of radio, has begun a campaign for the purpose of educating farmers in the practical everyday value of radio on the farm. The importance of this movement to the radio industry may be judged by these facts:

The population of the United States is one-third farmer. But, economically, the farmer is more important than is his voting power. He possesses *one-half the country's buying power.*

Because of his daily need of weather, crop and market reports, and because of his need for the recreation and educational means furnished by radio, the farmer is, potentially, *the nation's biggest user of radio.*

The National Radio Chamber of Commerce has first hand information in the form of letters and telegrams from hundreds of farmers' organizations in New York, New Jersey, Pennsylvania, Ohio and other states, and from the national organizations, which indicate that the leaders among the farmers are keenly interested in radio.

The National Radio Chamber of Commerce has been assured by these leaders of their co-operation in such a program.

The manufacturers and distributors of radio equipment are entering into the plan and are sending out demonstration parties with receivers and loud speakers, the chamber securing for them also the privilege of exhibiting their lines and taking orders.

The demonstrations have so far been chiefly confined to "County Picnics." Those in New York State occurring in September have an estimated attendance of more than 160,000, more than half of which will be covered by demonstration. Following these picnics, the county fairs furnish the next opportunity to reach the farmers in large number. These are beginning now and extend well into the fall and offer ideal opportunities for educational work of this sort.

The National Radio Chamber of Commerce calls upon all manufacturers and distributors of radio equipment, regardless of affiliation, and all manufacturers' and distributors' organizations to assist in this movement, co-operatively, if possible—independently, if they must.

It is "seed sown upon good ground!"

New Radio and Electrical Firms

Ponder Motor Manufacturing Corp., Wilmington, Del., $2,500,000. (Colonial Charter Co.)

American Batteries, Dover, Del., $1,500,000. (U. S. Corporation Co.)

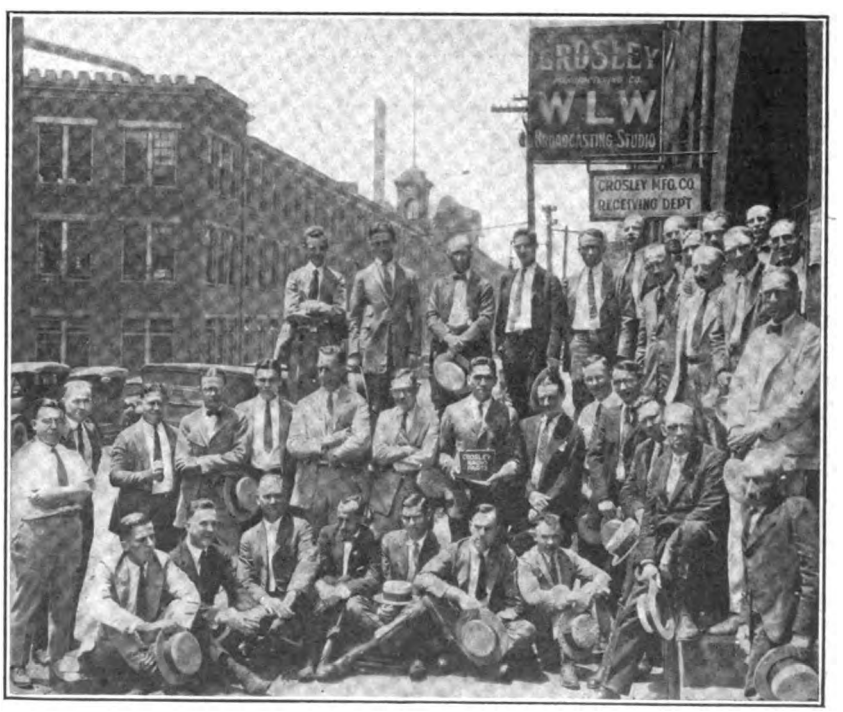
Newbrook Radio Sales Corp., New York City, $50,000; H. H. Southgate, S. I. Godley. (Attorney, S. Sternfeld, 15 Park Row.)

A Lively Radio Sales Aggregation



Delegates to the first radio sales convention held recently by the Crosley Manufacturing Company at Cincinnati. The picture was made at the entrance to the company's manufacturing plant, which also houses Broadcasting Station WLW

A Radio Song Prize Contest

MR. FRED FISHER, of the Fisher Music Publishing House, New York, announces that he has completed arrangements with I. R. Nelson Co., operators of WAAM, Newark, N. J., for a novel popular radio song contest that will start September 11 and continue through seven broadcasting evenings until September 27.

Mr. Fisher's new song hit, "M. T. Pocket Blues," will be broadcast each of the seven evenings by Fisher's song artists at WAAM. The contest is as follows:

First Contest—A prize for best letter of not over two hundred words telling why the writer liked or did not like "M. T. Pocket Blues." Prizes: First, one year's subscription for RADIO WORLD and one pair W. E. phones. Second, two Victor records or one piano roll.

Second Contest—A prize will be given for the best funny chorus written by any one who hears the WAAM contest. Prizes: First, two rolls or two Victor dance records, and one pair W. E. phones.

Third Contest—For radio fan sending in letter from farthest distance one copy of all the Fisher song hits will be given with a pair of radio ear phones.

Fourth Contest—The first ten telephone calls on each of the nights will receive an autographed copy of "M. T. Pocket Blues" by the composers, or each copy will be autographed by James Barton who featured this song in "Dew Drop Inn" at the Astor Theatre. In all, this will make seventy copies of the song that will be given away.

The following nights have been selected for the broadcasting contest of "M. T. Pocket Blues": September 11, 8.00-8.40 P. M.; September 13, 8.40-9.00 P. M.; September 18, 9.15-9.30 P. M.; September 19, 10.00-10.30 P. M.; September 20, 8.30-9.00 P. M.; September 25, 8.25-9.00 P. M.; September 27, 8.25-9.00 P. M.

All letters must bear the post mark of September 30 or before. Announcement of awards will be made October 17 at 8.40 P. M.

Radio Trade Notes

Anthony C. Budenkaye, 45 First West St., East Plymouth, Pa., informs RADIO WORLD that he intends to open a radio school this fall.

* * *

Joaquin Sangenis, Perla No. 15 (Gracia), Barcelona, Spain, wants to get in touch with manufacturers of tubes and dealers who stock UV199 and other tubes.

* * *

Alcon Electrical Supply Co., 86 Walker St., New York City, has been placed in the hands of Joe Healey as receiver. Liabilities about $9,000; assets about $3,000.

The Wireless Oracle

By Hirsch M. Kaplan

THE Skinner Organ Company's recital is a fitting conclusion at any evening's programme, but more so to a Sunday.

Have you noticed the revival of all the old popular and classical music during the past few weeks? Suppose the new music is slow in the coming or else the old is the best after all.

WBZ gave an organ recital that was on a par with many of our local ones.

Of all the programmes rendered by Roxy and his troupe this week's was by the far the best of them all. "Day by Day In Every Way They're Getting Better and Better."

See where this column must do some good, for as you might have noticed and as was suggested, the Alpha Syncopators and Bruno Brothers' Chin Lee Orchestras were with us again.

Lemme whisper somethin' to you! If you enjoy good plays with plenty of good music watch the programmes of the daily papers for when WGY is to broadcast a play, and take my word for it you will spend an enjoyable evening. Only the other evening they broadcasted a comedy, "The Country Boy," and it sure was the berries.

Giving dinners of welcome these days is getting mighty popular. First, they gave a dinner for our famous jazz king, Paul Whiteman, and this time it's for his second best, Paul Specht.

I suppose that many of you farmers in the vicinity of New York City have missed the noon market reports from WJZ. Well, don't let this bother you for if you will only tune a little higher you can get them from WEAF.

Phil Lunberg and his orchestra came through in fine shape from station WJAX of Cleveland, Ohio.

Another ivory tickler that made a hit with me is Mr. Brow.

WFI "verniered" its way through with a 75 per cent. orchestra.

WBS, your phonographic programmes may be all right, but the modulation of your station makes them sound worse than terrible.

"We have been assigned the call letters KDYR," writes the Pasadena, Cal., *Star-News,* but as Rube Goldberg says, "It doesn't mean anything," for "Yes! They have no transmitter" as yet.

It sure was some treat to have our old friend Betsey Ayres with us again. Yes, and as good as ever.

Congratulations, WDT, your modulation has improved.

If between six and seven P. M. you should hear a station offering a programme of orchestra selections interrupted occasionally by the giving of baseball scores, then you may be safely assured that this is station WFI, Strawbridge & Clothier, Philadelphia, Pa.

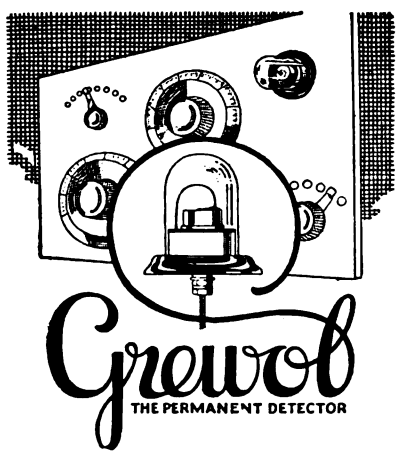
Paul Specht and his orchestra from station WMAF, "Way Down East" or "The Land of the Pilgrim Fathers," helped us to spend a pleasant hour.

The B. C. L.'s in the vicinity of New York City have long been crying for a Silent Night. This could be easily obtained if WHN would agree not to have a late programme on an evening when WDT was silent. Don't you think, WHN, that you are on the air long enough each day, and could afford to set aside a night for the dx fan? Think it over.

May Singy Bren sure can "Say It With a Banjo."

Edwin Franko Goldman nighted us for the last time other night. We sure will miss you, Frank, but let's hope that you will soon be with us again in the near future. So long!

WAAM, although a small powered station and on a low wave length, still makes itself conspicuous by offering popular programmes through a station that can rank with the best. That's the stuff. You sure do set a fine example for your complaining brothers.



Grewol
THE PERMANENT DETECTOR

FIXED ADJUSTMENT

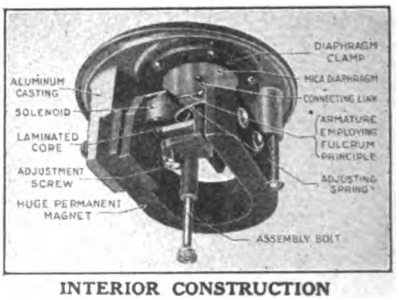
THE TRINITY LOUD SPEAKER

TYPE "A1"
21" FIBER HORN
$25.00

TYPE "B"
(For Phonographs)
$12.50



INTERIOR CONSTRUCTION

An ear phone is an ear phone no matter how fancy the horn that covers it may be, and, due to the delicate construction of an ear phone it is utterly incapable of giving true tone reproduction, especially, when relatively large currents are passed thru its coils, such as the output of a two-stage or power amplifier.

The Trinity Loud Speaker element embodies the well-proven and tested principles of the phonograph reproducer with the soundest principles of electromagnetic design best adapted for loud speaker operation. It is not an ear phone when placed on a head band and a loud speaker when covered with a horn. It is a sturdy loud-speaking element ALWAYS.

All Broadcasters Urged to Join the National Association

EDITOR, RADIO WORLD: We have this day received what we believe to have been intended as a most threatening letter from the American Society of Composers, Authors, and Publishers, signed by Mr. J. C. Rosenthal. It particularly interests us to note how they refer to us broadcasters and the radio audience as "beggars who cannot be choosers." We believe that they have endeavored to say, in most adroit language, "We have the legal decision against you broadcasters (Federal Judge Lynch's decision in favor of Witmark Publishing Company against Broadcaster Bamberger). Now you *must* pay us, even though you do popularize our music." Frankly, they are right so long as we, the broadcasters, remain an unorganized entity.

Unquestionably the present copyright law favors this society, who, I am advised, were instrumental in having the law enacted. The society is a highly organized association with plenty of funds to employ and maintain their highly paid, highly skilled attorneys throughout the United States and unquestionably there will be a multiplicity of suits started within the next few weeks against many of the broadcasting stations throughout the country. Just so long as the present copyright law exists, we believe they can win against any broadcaster using their music.

They state in this communication that they will license the broadcasters to popularize their songs at tributes ranging from $200 to $5,000 per annum. Their fee for the first year will probably be small, or they may offer licenses to some of us free to get us to recognize their so-called rights, but the tribute will unquestionably be increased from year to year after once we have recognized them. This is not all. The next step will be the musicians' unions, then the payment of artists, and then the end of broadcasting.

Is it not high time that all the broadcasting stations got together by joining the National Association of Broadcasters, for protection if nothing else? If we remain unorganized, it is only a question of time when most of us will be forced to pay tribute to this and other societies. We have in prohibition an excellent example of the power of an organized minority against an unorganized majority. Do we want a repetition of this in broadcasting?

Station WJAZ is a member of the National Association of Broadcasters, which has its executive offices at 1265 Broadway, New York City, and unqualifiedly endorses it. We are receiving from the association their weekly release of new songs, on which we have not only the temporary, but the permanent rights to broadcast, even after *we* have popularized each new selection. Our orchester leader, Mr. Dan Russo, of the Oriole Terrace Orchestra at the Edgewater Beach Hotel, is not only playing our new releases received from the Broadcasters' Association for broadcasting purposes, but is using them as his dance numbers, because they are so excellent. The Chicago Daily News, who broadcast from the La Salle Hotel and who are also members of the National Association of Broadcasters, tell us that their orchestra leader, Mr. Scheetz, is doing the same.

Our station broadcasts *only* the music supplied by the National Association and other copyrighted music, on which the copyright has expired, and we, with pride, say that our programs speak for themselves.

We must also be highly organized, so that we may have a voice in opposing the passage of many bills proposing radical radio legislation, which bills are now in the files in Washington.

We are sending this letter out unsolicited, but we trust its message will bear fruit. It behooves every one of us broadcasters to get behind this National Association, join it, use their music, and thereby make *radio* music the most popular in the country and save ourselves from being forced to pay tribute to a society that has *no interest in us other than to collect fees.*

Cordially and sincerely yours,

Velma Carson Visits a Broadcasting Station

VELMA CARSON, who has contributed several articles to RADIO WORLD, recounts in *Farm and Fireside* for September her experiences while visiting a radio broadcasting station for the first time. Miss Carson's story, in part, follows:

Six months after first marveling on our farm at the powers of the radio, chance brought me across the country from whence the voices had come, to its home in East Pittsburgh. I would hunt up KDKA, I promised myself, and see what supernatural agencies were at work.

Arriving at the plant of the Westinghouse Electric and Manufacturing Company in East Pittsburgh one evening, I found myself at a door marked KDKA, near the main entrance of the plant. Maybe we had heard something real after all. I began to be sorry for my doubting. Or else they were going a long way to carry out the delusion.

I entered an office where a dozen or more persons were sitting about chatting and visiting. Violin cases, music rolls, and manuscripts were lying about in a convincing manner. Visitors were taking turns at a radio receiving set on the desk. A pleasant young man walked about playing host. Another tapped furiously on a telegraph instrument. A breath of excitement was in the air. A company taxicab stopped outside, and a couple rushed in breathlessly. It was twenty-five minutes after seven, and the world sat waiting. We all looked expectantly toward a door marked "Studio"—"SILENCE." Then it opened, and we all filed soberly into a muffled room. We were quiet, partly because the strained stillness of the room affected us into further silence, and partly because most of us who were there for the first time felt we were in the presence of some great unseen, awesome force. The studio is about 20x30 feet, completely lined and draped with cloth and burlap and without windows, so that there will be no echoes and no penetration of sound from the outside.

The draperies are a warm gray. Palms, rose and gold floor lamps, a grand piano, a thick gray velvet carpet, and gay tapestries and cushions make it a very lovely room. One likes to think that the Little Symphony Orchestra plays on a well-set stage. When I go home to the farm again and listen to KDKA I shall always see in the concert a happy group of people in the lamp's rose glow, gathered to give me their best talent.

It seemed to me, as I sat there waiting, that I was about to witness a startling phenomena. I expected at least thunder and lightning to accompany the sending of the concert. I once visited a wireless station where the messages start off with a convincing popping. This would surely be greater!

It is now twenty-nine minutes after seven. The announcer is frantically asking everyone how to pronounce Macheroni, the name of a composer someone is to interpret. He gets a dozen different versions, then makes a run for the dictionary. The announcer takes great pains to see that every word is pronounced with absolute correctness.

At one end of the studio, in a glass box projecting from the wall, flash the words "Set On." This means that the radio is ready any time the speakers are. Two men come in and work with the sending apparatus. One speaks into the microphone, and the other asks over a telephone if everything is in working order.

The microphone looks like a tin can swinging on the end of a fishing pole stuck in the ground at right angles. The "pole" is a mahogany bar of wood. The "can" is neat and black. But one gets the willow-pole-tomato-can idea just the same.

The clock points to seven-thirty. A button is pushed and simultaneously the signal box flashes in large letters "SILENCE" to the microphone and says with emphatic articulation, "You are listening to KDKA, East Pittsburgh, Pennsylvania. The first number on the program will be Schubert's Serenade, played by Mr. Tom Jones." We hear the opening chords by Mr. Jones. That is all there is to see or hear. The program is on. Some family out in Michigan has put on the loud horn and settled down for the evening.

The tenor who is to follow the piano solo is nervous. He has a right to be. He is about to sing to 2,000,000 persons. He never in all his life before has had an audience of more than 800 people. And even though he is an excellent singer his audiences have seldom numbered more than 200 persons. He is a church singer, and has been used to appearing before his own acquaintances and friends, who overlook his mistakes, and who also, by the way, take his excellency for granted. Until now he could fall back upon a smile or a gesture to carry him through. But only the actual merit of his singing will please this vast audience.

The piano solo ended, the announcer signs off, and the signal says to "Stand By." The radio couldn't hear us talk any more. "Don't be afraid. Just put your pep into it," the violinist encourages the tenor.

Until a few months ago she herself was as unknown to anyone outside her home city as is the rose in the desert. Now she gets familiar and favorable mention out in Higginsville, Illinois.

The violinist played with all her heart. She had received many personal letters from all over the United States since her radio debut, and when she tucked her violin under her chin it was to no abstract audience before which she was performing. She played to the bedfast woman who had written to her from Ohio; to the old, old man who had painfully scribbled a thank-you note from West Virginia; to a little crippled boy she had become acquainted with out in Wisconsin; to the men of the Michigan lumber camp who had sent her their appreciation; to the Arkansas farm family who had told her they would be listening in on this night; and to many others near and far. She played better for every letter that had come to her. She has the joy of giving to appreciative people.

IMPORTANT NOTICE
While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

Station WHN Interferes With Amateurs

Editor, RADIO WORLD:

I hope that station WHN can be persuaded to sign off two or three nights a week at eleven o'clock in order to give "DX" stations a chance to be heard, as you know that a good many out-of-town stations are at 60 meters. It is impossible to hear anything around that wave length until WHN signs off. In the spirit of fairness I think that they should comply with this wish.

I have spoken to over 25 people in my neighborhood about this matter and they all agree with me fully. Trusting that something can be done regarding this,

Sincerely yours,
R. D. EMMERICH.

322 West 100th St.,
New York City.

RADIO WORLD in England

Editor, RADIO WORLD:

Congratulations on the production of such a wonderful periodical. I look forward to getting the latest copy each week with lots of joyous anticipation.

I am a real novice, just being bitten by the bug and am dying to get hold of a circuit suitable for our English broadcasting.

In my opinion we here are miles behind you in radio matters and so, therefore, why should I not have a real American circuit? Unfortunately we are only allowed to use a regenerative hook-up under certain conditions and at certain times. Lucky American fans!

Yours faithfully,
C. HARWOOD KING.

German Apparatus Installed in Norway

APPARATUS for the radio station which is to be built at Bergen, Norway, has been received in that country, according to advices to Washington from Consul George N. Ifft, and preliminary tests have assured the government of its efficiency. Because of the failure of an appropriation for duplex apparatus which would enable the transmission of messages both ways simultaneously, and the failure of the plan to establish a telephone line between Bergen and the Rundemanden radio station, the chief use of the new station will be for the transmission of wireless communications to ships at sea.

Actor Builds a Receiving Set

THE company playing "Merton of the Movies" at the Cort Theatre claims to be the only theatrical organization in New York City which has a radiophone receiving set that was assembled by one of the cast. The set was built by Howard Dale, who plays one of the extras in the film studio scenes. Dale was in both the United States Army and Navy during the war—being thereby rather an ambidextrous performer—and won a scholarship for wireless work offered by the Y. M. C. A.

Wireless Will Control Future Wars

PROFESSOR A. M. LOW, scientist and inventor, whose work during the World War was highly valued by the British War Inventions Board, contributes a prophetic article to the Fortnightly Review on the sort of warfare that may be expected a hundred years hence. Among the things he expects to play a part in future warfare are:

Jets of water, charged with electricity, to kill horses and men.

Wireless telephony, sight, heat, power and writing.

Wireless control of tanks and airplanes.

Battle plane engines developing wireless power to destroy aircraft within hundreds of yards.

Wireless heat to destroy European regions.

Giant transport airplanes with incredible speed.

Secret war plans ferreted out by wireless telephone and sight, the future war eyes and ears. Propaganda striking terror into every home by means of wireless receivers which will be more common than the telephone today.

FOUR REASONS FOR ADVERTISING IN RADIO WORLD'S FALL BUYERS' NUMBER

1 At four dollars an inch (yearly contractrate) 74,000 radio-buying readers learn of your goods—a greater number of eyes than four dollars can reach in any other radio advertising medium.

2 Radio World gives **quicker results**—i. e., advertising copy received by Thursday p. m. is published and on the news-stands the following Wednesday morning.

3 A Weekly has greater **reader interest**—the Saturday Evening Post, Literary Digest, Iron Age, are Weeklies. Radio World, the big success of radio, is published every week.

4 Advertising is a gamble. Life itself is. A gambler bets his money on past performances. Radio Corporation of America tried out **Radio World,** then gave us a yearly contract. Magnavox tried us for small space thirteen times, and have just renewed for fifty-two times, using pages. The Federal Telephone & Telegraph Company investigated us from every angle for weeks, then gave us a fifty-two consecutive issue order. A four-time trial of Radio World almost invariably ends with a fifty-two time contract at $120 per page net or $4.00 an inch.

DATE OF THIS IMPORTANT ISSUE—OCTOBER 6

(LAST BLACK FORM CLOSES SEPTEMBER 27)

Special service and value to advertisers in Radio World's **FALL BUYERS' NUMBER:** All advertisers who give us copy for quarter page or more space in Radio World's **FALL BUYERS' NUMBER** will, on request, have their announcements appear in **two colors at the price of one**—in case copy is in our hands by September 24.

Write, wire or phone now for special positions

Will take the place of other rheostat or filament control without redrilling panel.

The filament kontrol of infinite adjustment

FIL-KO-STAT

enables you to hear stations you have never heard before and gives absolutely noiseless operation

Missing What You Get

Your set is probably bringing in D X stations you never heard because your rheostat cannot control your filament action. The Filkostat gives infinite adjustment and enables you to *magnify* the weak stations and bring them in strong and clear.

Paul H. Woodruff, Editor Industrial Power, Chicago, writes that after installing the Filkostat he picked up KHJ and KWH, 2000 miles on a single tube regenerative detector.

Eighteen Times More

Laboratory research proves FIL-KO-STAT to have a fine adjustment area (i. e. ability to control filament heat and elextronic flow) eighteen times greater than that of the wire rheostat and several times that of the next best filament control.

FIL-KO-STAT cylindrical design is the outcome of extensive experimentation. It gives the resistance element sufficient radiating surface to eliminate excessive heating. This is one of the outstanding FIL-KO-STAT features.

Adjusted For All Tubes

You have no screws to tamper with on the Filkostat. No adjustments to puzzle you. Experts have taken care of this for you. The Filkostat is not just fabricated. It is a laboratory product triple tested before being sent out and scientifically adjusted to the ideal "off" position for **UV200, 201, 201A, WD11, WD12, UV199, DV6A, W. E. Peanut, *and all other tubes.***

No Wires—No Discs

The makers of the FIL-KO-STAT express their confidence with an unconditional guarantee. Filkostat is assembled by precision craftsmen. It contains a resistance element so finely divided that further resistance is impossible. *There is nothing to break or chip.* When you buy a FIL-KO-STAT you know that you are not only getting the finest filament control made but that, its reliability and durability are fully and completely—

GUARANTEED BY THE MAKER

DX INSTRUMENT CO. HARRISBURG PA

Professional Testimony

The RADIO GUILD writes "comparisons with every reliable filament and current controlling device now available proved Filkostat far superior to all other types of filament controls giving the closest possible adjustment of any type of filament tube and the only instrument which could be used for *all tubes* giving equal critical adjustment at the high resistance as at the low resistance."

Amateur Enthusiasm

Out of hundreds of testimonials, we quote

W. R. Hagedorn, Hay Springs, Neb. — "tried 4 different Rheostats. Filkostat beats them all."

W. R. Williams, Woodsfield, Ohio "Filkostat on a single circuit regenerative giving excellent satisfaction. The noiseless operation means a great deal."

S. George Kerngood, President of Bluebird Hats, New York "only since using it I realized how wonderful a set can be made."

Dealers' Delight

Dealers everywhere are delighted with Filkostat. Its noiseless operation has increased the joy of Radio and the "fans" are recommending it. Here's one of many interesting dealer letters.

E. M. Pace, Vicksburg, Miss. writes — "Send carton ot Filkostat as early as possible. Sold sample Filkostat 5 minutes after it was received. It is proclaimed by the fan that bought it as being 100% better than the best."

A Booklet You Will Want

By Walter C. Garvey, of Evening World's Radio Section, Editorial Staff, Handbook of Helpful Hints for Radio Set Builders, includes tables charts, legends, statistics and 16 carefully selected hookups with diagrams and full descriptions. Reading this interesting book we discovered Mr. Garvey recommended the FIL-KO-STAT. We bought an edition of the books and will gladly send a copy anywhere at handling cost 10c. postpaid.

This Summer Has Shown That Radio Is Not Seasonal

THIS summer has demonstrated that radio is not a seasonal interest and pleasure. It has been commonly supposed that warm weather seriously interfered with reception and this belief has, in the past, lead many to hang up their headphones from May to October.

It is true that static sometimes interferes and that long distance records are not as frequent in summer, but successful reception can be obtained from stations within 500 miles on all but a very few evenings.

Letters received by WGY, the Schenectady, N. Y., broadcasting station of the General Electric Company, indicate that the programs have given real pleasure to vacationists at the shore and in the mountains. The radio public has made the radio set a necessary part of its vacation equipment. It is not unusual, on camp sites, to see the tourist rig up his receiving set soon after the tent is erected for the night. The evening campfire becomes more attractive under the sway of music provided by some distant station. Summer hotels have included radio sets among their attractions and many dances are held to radio music.

Sixty-five Boy Scouts, camping at Stewiacke, Nova Scotia, heard WGY during their two weeks camp, according to a letter recently received at the station. "We are using a homemade set," wrote the camp radio operator, "with two stages of amplification and a loud speaker with no power amplifier. Using this set we are all able to hear, in fact the music may usually be heard a hundred yards around the radio tent. Modulation is extremely good."

Ivan H. Walker, of Ottawa, Canada, wrote WGY complimenting the station on the broadcasting of the play "The Royal Mounted," which came through "clear and distinct." Mr. Walker explained that he was camping with a party. "We have our set with us and are getting excellent results with no interference from others tuning in. All one has to do is to get tuned in and then sit back and enjoy everything."

John P. Badger, a Malone, N. Y., attorney, informs WGY that he moved his radio set to his camp in the Adirondacks, eight miles south of Malone, expecting that he would have trouble in receiving. "However," he explains, "although the aerial is strung among the trees and the ground is full of minerals, your station comes through the loud speaker as clear as a bell."

Italian Broadcasting Soon

AN agreement between a number of Italian radio manufacturers whereby a broadcasting station is to be constructed and put in operation has been announced. Up to the end of July there had not been any regular broadcasting in Italy.

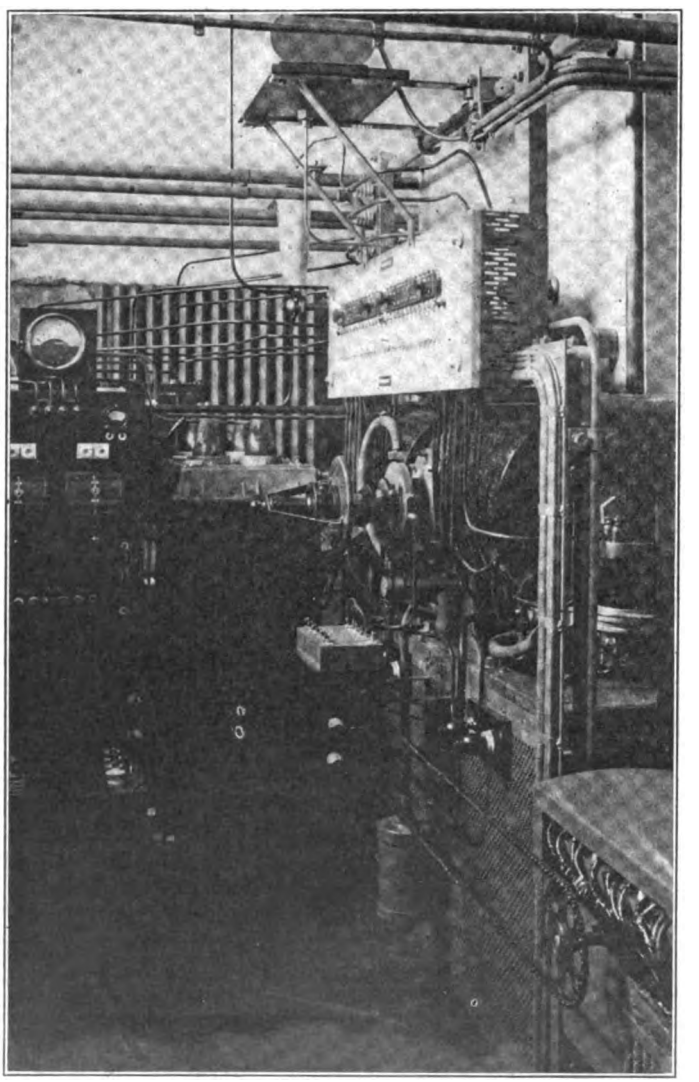
A 10 KW Lorenz-Poulsen Arc Transmitting Station

By Dr. Alfred Gradenwitz

AFTER recently undergoing a number of important improvements, the Königswusterhausen Wireless Station, formerly used for military purposes, has been converted into a big commercial station, operated by the German Postal Department. Of its two Lorenz-Poulsen arc transmitters of 10 KW and 32 KW respectively, it is intended here to describe the former, which may be considered a model installation of its kind, and which under economic conditions enables a thoroughly efficient and reliable permanent service to be maintained. Before proceeding to describe this installation, the fundamental characteristics of an electric arc wave generator may be summed up as follows:

The conversion of continuous current energy into high-frequency current energy is greatly assisted by the electric arc being produced in an atmosphere of hydrogen or some gas containing hydrogen, the great ionic speed of which causes the voltage along the arc to be altered and thus the cathode fall used for heating the negative crater to be reduced. On the other hand, a magnetic field at right angles to the current (or a "magnetic blower" as it is termed) is caused to act on the electric arc, which then constitutes a shifting conductor in a magnetic field of force, the arc being deflected or even blown out entirely. Provision is also made for the electrodes slowly to rotate round their axes, thus enabling fresh portions of these electrodes to be burnt and insuring a uniform consumption of carbons, as well as a constant length of arc.

Inasmuch as the arc current and the magnetic field arranged in series are dependent on one another, arc regulation takes places quite automatically, fluctuations in the electric arc being reduced to a minimum.



Rear view of Lorenz-Poulsen 10 K.W. Transmitter.

Special features adopted in connection with the Königswusterhausen transmitter comprise:

Separate excitation has been adopted side by side with the self-excitation of the magnet coils, thus avoiding any disturbing noises in the arc. Moreover, the positive electrode is a rapidly rotating copper electrode cooled by flowing water, the negative carbon electrode rotating at a slower rate in an opposite direction. A reliable intermediary circuit was inserted with a view to improving the tuning capacity of the transmitter and eliminating upper harmonics. A new wireless telephone method was finally adopted.

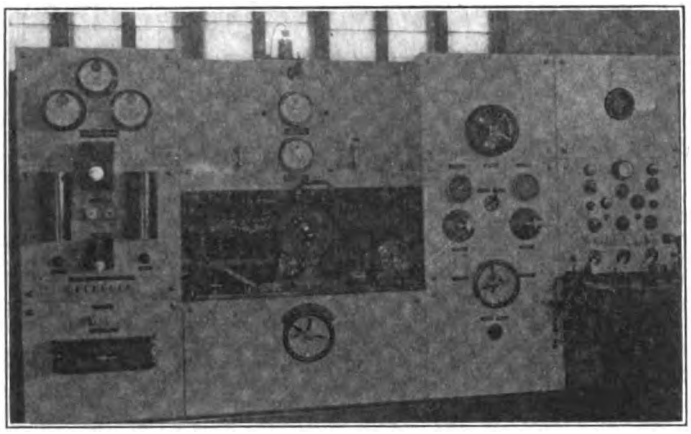
The new 10 KW Lorenz-Poulsen transmitter is worked within a wave range of 2,600-9,000 meters at a primary tension of 650 to 800 volts and is connected up to 3,000 c/m. antenna in the case of the shorter waves, and to an 8,000 c/m. antenna in the case of the longer waves. The maximum load on the generator in waves, and to an 8,000 c/m. antenna in the case of the longer

Digitized by Google

waves. The maximum load on the generator in permanent operation is 50 amperes direct current.

The wave generator, the direct current and high-frequency switches as well as the telephone apparatus are installed on an iron tube frame, comprising four panels.

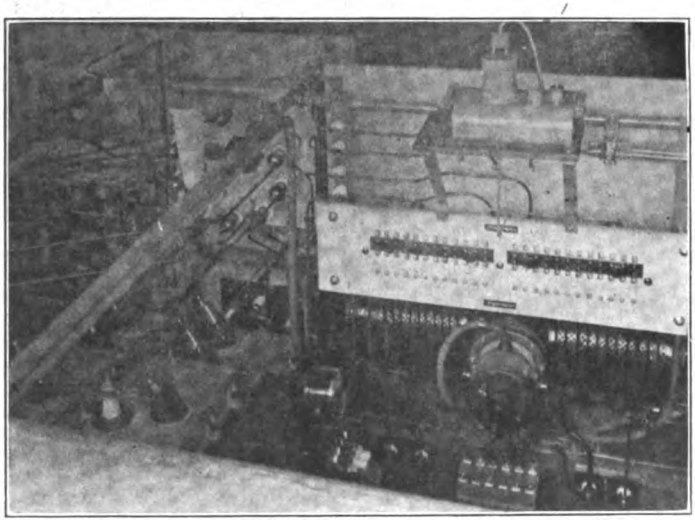
The direct current panel, which in turn consists of



10 K.W. Lorenz-Poulsen telegraph-telephone transmitter.

three marble switchboards, carries on the top the ammeter for the separate excitation of the magnetic field, as well as an ammeter and voltmeter for the current feeding the generator. The central switchboard comprises the block relays, a double-pole switch-out for high tension, and one for low tension, as well as several fuses and rotary switches.

The generator panel is arranged between two marble switchboards, the top one carrying to the left the water-flow controller, and to the right an alcohol controller, as well as two ammeters controlling the intermediary and antenna circuits respectively. A regulating resistance consisting of a resistive band kept together by an asbestos fabric is varied by degrees by



Back of central part and left side of 10 K.W. Lorenz-Poulsen telegraph-telephone transmitter.

means of a large handwheel, and enables the current intensity in the electric arc, and accordingly, the radiated energy, to be altered between its normal figure and one-third its normal figure.

The high-frequency switches are arranged on a similar three-sectioned switchboard, the upper marble switchboard carrying the handwheel for operating the antenna step switch, while the central switchboard comprises tuning apparatus for the antenna and intermediary circuits. A switch enabling a variable coupling to be obtained between the intermediary circuit and the antenna as well as the switch for transmitting with or without the intermediary circuit are provided on the central switchboard. A selective switch for passing from telegraph to telephone operation and vice versa is arranged on the lower switchboard.

The fourth panel likewise comprises three sections, the top one carrying the oscillation controller and the central one the various instruments and handles for operating the telephone apparatus, while a small table carrying on the left the wave controller, is installed immediately in front of the lowermost section.

The Lorenz-Poulsen generator comprises a flame compartment, 12 magnet coils, an alcohol dropper, the cooling device and the ignition. The flame compartment containing the wave generator proper is a metal casing in which the electric arc is burning between two electrodes.

A double-walled water-cooled sleeve disposes of the considerable heat thus produced. The carbon electrode is kept by a carbon-holder surrounded by a sleeve and carried along in its rotation by friction. The magnetic field in the midst of which the electric arc is burning is produced between two iron cores penetrating sideways into the flame compartment. The north pole will be found to be to the right, and the south pole to the left of the looker-on, the current thus flowing away from him, while the electric arc, being a current-carry-

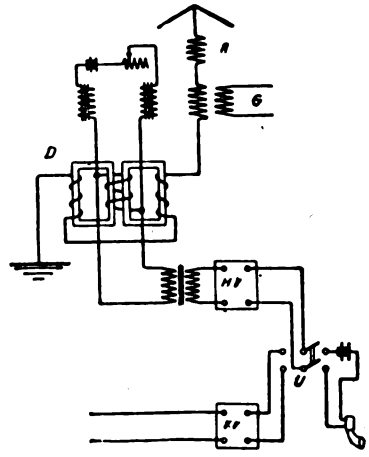


Diagram of Connections Used in Radio Telephony — G, Poulsen high-frequency generator; A, antenna system; D, choking coil referred to in the text and comprising separate iron cores; Hv, two-valve main amplifier which in the case of speech or music immediately striking the microphone is quite sufficent; VV, a one-valve preliminary amplifier inserted in the case of remote action on the microphone; U, a switch for passing from one service to the other.

ing conductor, is blown upward. The cores are made of Swedish ingot iron and are closed magnetically by an iron bow below the flame compartment. Six magnet coils are provided on each of the iron cores. The alcohol dropper supplies the alcohol required for forming a hydrogen atmosphere through an apparatus where the liquid owing to very high temperature is evaporated. The water required for cooling the flame compartment is derived from the water supply.

The electric arc is lighted by pressing the front carbon electrode with the hand against the back one, thus short-circuiting the electrodes. A spring on the carbon holder immediately throws the front electrode back again, thus allowing the electric arc to form. Immediately after lighting the arc, the short-circuit relay for short-circuiting the series resistance of the arc is operated.

The variometers, in conjunction with the transmitter coils, are used for continually bridging the stages provided by the sub-division of the transmitter plant in passing from one wave to the other, and in obtaining an accurate tuning. They are made up of two cylinders rotating within one another, the coils of which are arranged in series, and are placed in an oil bath, to prevent excessive heating.

The transmitter coils (two for the antenna and two for the intermediate circuit) in conjunction with the

Electrical Imp Plays with Radio Aerials

HARTFORD, Conn.—Electrical imps play strange pranks with the ether, but engineers connected with the local lighting plant have just about given up their search for a particularly vicious specimen which has been annoying broadcast listeners whose aerials are adjacent to a five-mile series lighting line.

A weird sound, described in electrical terms as a "60 cycle roar," pounds into their receivers at the most unfortunate times and even the programs from nearby broadcast stations are tangled up in a boiler factory medley that drives them from the phones. And there is no let-up to the racket.

After complaining to local dealers that their receiving sets were no good, and being assured that they were in first class condition, scores throughout this section appealed to the American Radio Relay League and the local electric light company.

A tiny loop set, operated by officers of the League, revealed the interference as coming from the power line. When the generators were shut down for a few minutes as a test measure, the roaring noise vanished, proving conclusively the source of the trouble.

An examination of the transformers showed them to be in perfect working order and a night investigation revealed no sparking. The "best line in the system" was what the engineers reported, but those who try to hear KDKA through the electrical brass band are not so easily appeased and threaten all sorts of things. A freak line, sure enough, say the listeners while the imp continues to disport with their antennae.

Royalty Listens In

RADIO has been very slow in taking hold, in England, mainly because of the fact that the British Government has put restrictions on it as to what type of receiver should be used, and the conditions under which it could be used.

For that reason, radio has not been as popular in the British domain as it might have been. Even at that, restricted as it is, it has struggled and struggled to the fore until at the present time the British Government has allowed broadcasting stations to be opened and has looked in a more kindly light than formerly upon the "radio listener."

The illustration opposite shows the Duke of Connaught, one of England's royal family, listening in on a Gecophone, an English set, at Bagshot Park, his Surrey home. The set was installed and radio heard for the first time at that particular place. It is not known whether the installation was permanent or not, but if the English "radio bug" bites with the same infective spirit on that side of the water as he does on this, a safe supposition would be that if the installation was merely a demonstration, that it would soon be a permanent one.

Handicapped as our English brothers are in radio, they are making rapid strides. And as they seem to be taking hold in good style, it is hoped that we may soon be able to hear of some revolutionary experiments that have been worked out, as a result of their restrictions.

(C. P. & A. Photos)
The Duke of Connaught listens in through a British receiver.

(*Concluded from preceding page*)

variometers, serve to adjust the wave length, and are connected up in series with the variometers, any wave length betwen 2,600 and 9,000 meters being readily adjusted for by means of convenient sub-divisions.

The radio telephone apparatus is worked on the Pungs-Gerth system of magnetic control of the high-frequency current, which can be used in connection with any continuous wave transmitting scheme. It is based on the following principles: As a coil comprising even a finely-subdivided iron core is traversed by high-frequency current, the amplitude of the latter, on account of losses by hysteresis and eddy currents, is practically reduced to zero, the choke acting like a high resistance inserted into the high-frequency circuit. This damping effect of the iron can be compensated more or less by superimposing a direct current saturating the iron more or less and thus making it less effective magnetically. The high-frequency current can thus be altered within very wide limits by altering the direct current magnetization.

This arrangement enables a very considerable relay effect to be produced, great amounts of high-frequency energy being controlled by comparatively small amounts of direct current energy. The choking coils consists of two cores closed through iron and carrying a common direct current coil as well as two separate high-frequency coils, which are so arranged as not to produce any high-frequency tension in the direct current coil. A standard postoffice microphone responding to 1/100 KW is used, a two-valve or three-valve amplifier being inserted between it and the antenna, to control a nearly one million times higher amount of energy. This arrangement enables both speech and music to be rendered with practically absolute faithfulness, producing the illusion of immediate hearing.

Radio First to Report the Awful Japanese Catastrophe

By J. L. Bernard

RADIO gave the first news to a shocked world of the appalling destruction by earthquake and fire in Tokio and Yokahama and other Japanese cities, which began on September 1, and continued for several days.

As an island empire Japan had depended, principally until very recently, on cable communication for quick connection with the outside world. The repeated earthquake shocks, which launched one of the greatest catastrophes in history, not only destroyed the shore ends of several cables with their receiving instruments, but also through the upheaval of the ocean floor, probably severed the cables.

Thus was the disaster-stricken territory cut off from informing the world of its frightful plight—except for one means of communication.

By an act of Divine Providence the big radio station, its masts and equipment at Tamioka, 144 miles from Tokio, was spared intact.

The operator on duty at the Tamioka station, whose name is given in press dispatches as T. Yonemura, saw the fleeing refugees pouring past his post several hours after the first earthquake shock. Quick inquiry developed the startling news from the panic-stricken people and then Yonemura put a message on the air which was to startle and stun the world.

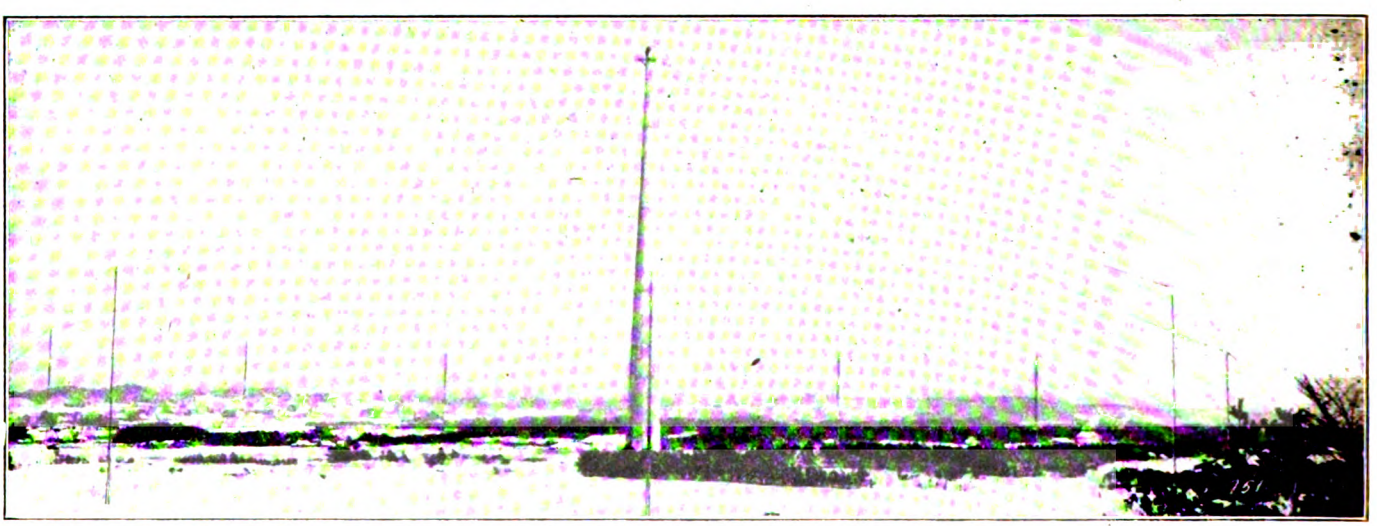
The San Francisco station of the Radio Corporation of America picked up the message first, relayed it instantly to the Associated Press which gave it universal currency through the daily newspapers.

Thus did radio play its vital part in giving the world news which necessitated relief measures on a tremendous scale which might otherwise have been delayed for days.

Locally, in Japan, radio stations have since been the only means of communication with the stricken cities. A number of naval vessels and merchant ships have been assigned posts at various ports to act as relay stations in getting radio messages to and from the disaster-stricken area.

The President of the United States has turned loose every government agency to aid in relief work, all red tape has been cut, the American Red Cross is raising a fund of $5,000,000 to aid the homeless and the hurt, and foreign governments are cooperating in all measures.

The lives that have been saved by radio in this one instance can never be counted, but they must number many thousands.—Editor RADIO WORLD.



View of the radio station at Haranomachi, Japan, showing the reinforced concrete tower 660 feet high. This is surrounded by a ring of 36 250-foot wooden masts on a radius of 1,300 feet from the concrete tower which is 60 feet in diameter at the base and 14 feet in diameter at the top. The station buildings are just to the left of the tower. This is the receiving unit, the transmitting unit being at Tamioka, which is remotely controlled by the operators at Haranomachi. The Japanese consider both these units as one station, known as the Iwaki radio plant. Neither station was affected by the earthquakes.

RADIO communication once again has demonstrated in the eyes of the world how indispensable an institution it has become in serving mankind during great emergencies.

It was radio that flashed across the Pacific first news of the horrible disaster visited upon the people of Japan when earthquake and fire laid ruin two of the principal cities—Tokio and Yokohama.

When the first shock was felt and fires set the cities ablaze the powerful transmitting station at Haranomachi established communication with the high power station of the Radio Corporation of America at San Francisco and at six ten A. M. Saturday the meager details of the catastrophe, as they were received at the corporation station, were delivered at once to the Associated, International and United Press. The violence of the earthquake soon after crippled the telegraph lines which link Tokio and Yokohama. Thus, the only channels of direct communication with San Francisco, the radio system, was isolated from the scene of the disaster until a swift courier system could be established. During these most severe disturbances in Tokio and Yokohama, however, the radio link between the two mighty stations separated by the vast expanse of the Pacific maintained constant communication with each other. Respecting neither the tremendous quaking of the earth, the swelling of the seas which swallowed many of the vessels in Japanese waters or the raging fires that consumed thousands of dwellings, radio waves laden with precious messages continued on their ethereal path.

The Radio Woman

FRIEND HUSBAND (who is always very useful around the first of the month for paying the bills) took a notion into his head last week to look over the receipted bills for the electric light for the past year. I had already done that several times, and noted the increase over what we had been paying. "Look here," he said after about a half hour's perusal of said bills. "Last year at this time our bills for light were just about one-third of what we are paying now. How come, lady? We haven't had nearly as many parties as we used to have." "Well," I retorted, "you insist on staying up till all hours of the morning listening in, and keeping the lights going. And then there is also that charger that you keep going three nights a week. But at the same time contrast the expenses you used to have for theatre and suppers and the money you lost playing bridge." I took my life in my hands when I made the last remark, because he is very touchy about his bridge playing. "Well, I guess you are right. Theatre tickets every week do amount to a little bit at the end of the month, especially when contrasted with a measly raise of $5 for lights." I would like to make a graph of the raise in lighting bills of those who have radio sets and compare it with a similar graph of the money that they saved by having a radio set. I think it would make interesting data for all persons concerned, don't you?

* * *

A friend of ours who has a wonderful house way out in north Jersey recently dropped in to see us, and, of course, we talked over old times. Naturally we drifted around to the present day radio craze. "Oh, my goodness, I do not know what I would do without radio! It really is too far to go to the country club every evening and the usual rounds of house to house parties are so tiresome. We are so far from town that whenever we decide to come down we decide to make a week end of it. With radio, we can keep right up to the second in everything and besides I think that Joe has shown me more attention evenings since we put it in." Well, that is what they all say, and I know that if broadcasting was to stop tomorrow that it would hurt more people than you could shake a stick at, because people have come to rely upon radio so much for entertainment and relaxation after a hard day that the world would seem to be an empty place without it.

(*Concluded from preceding page*)

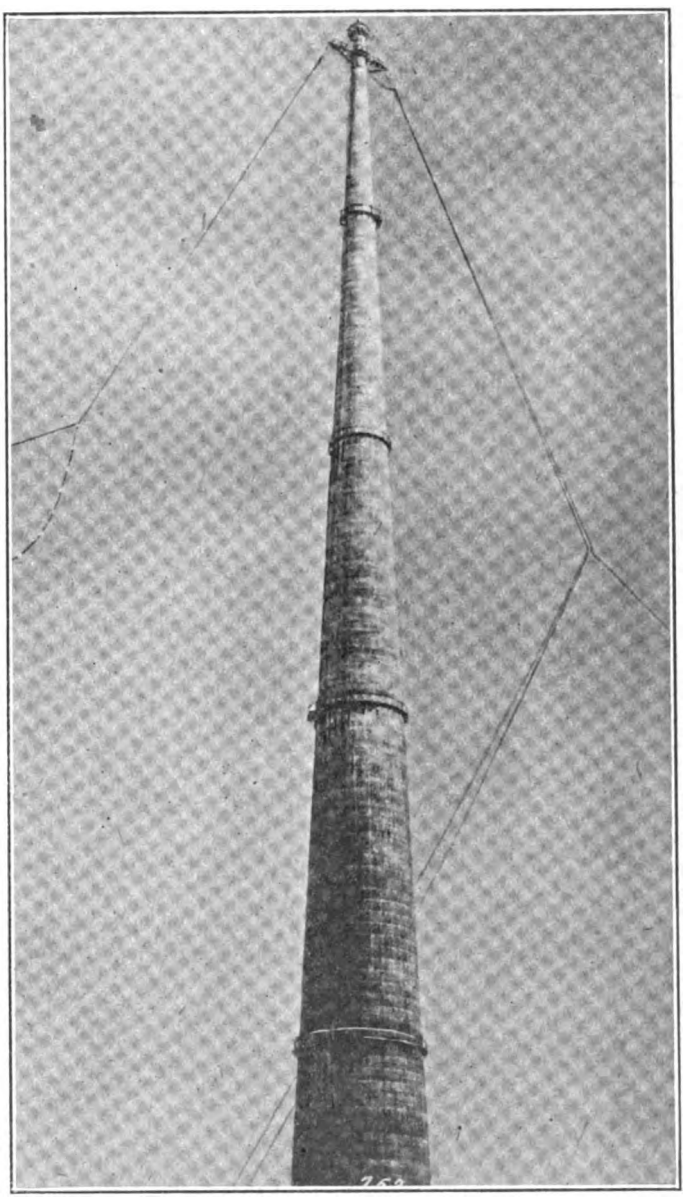
From the very beginning the superintendent of the Japanese radio station, Yonemura, and the operating staff under him labored heroically in dispatching with the utmost speed all messages that reached the station from the station in the interior. Yonemura not only supervised the operators at his station, but was unexpectedly called into service as a translator of the messages which were sent over the radio circuit to and from Japan.

It was perhaps by some strange freak that the Japanese radio station did not suffer damage. Fear was expressed that the giant concrete mast, rising to 660 feet and which supports the antenna at the station, might be rocked by the earthquake and shattered into bits. Fortunately, however, it weathered the test, perhaps due to its exceptional construction, which combines both steel and concrete.

Although the telegraphic facilities from the Japanese radio station to Tokio and Yokohama have been completely wiped out, service to other points inland is still intact. It is highly probable that Japanese engineers are sparing no effort to restore the more important telegraph lines feeding inland from the radio plant.

Since the military branch of the Japanese government is actively promoting internal radio telegraphic service, it is quite possible that an emergency radio relay system will be set up in the devastated regions for communication with the big station near the coast.

The largest radio station in Japan which communicates with the United States consists of a receiving unit at Tomioka and a transmitting set at Haranomachi. The distances betwen Tokio, Tomioka and Haranomachi are 155 and 178 miles respectively. The equipment used at the Japanese receiving station is essentially the same as that used at Riverhead, Long Island, by the Radio Corporation of America, and was



Close-up view of the reinforced concrete tower at the Haranomachi, Japan, radio station, pictured on the preceding page. This station is 178 miles from Tokio. It was probably outside the sphere of influence of the earthquakes, which accounts for its survival intact.

supplied by that company to the Japanese Government. The well known "wave" antenna, which is nine miles in length, is employed for reception on 16,300 meters. The transmitting station utilizes a 500 kilowatt arc set for communication on 14,350 meters. It was erected in 1921 and surpasses in power all radio stations on the island. This transmitter is controlled from the receiving station at Tomioka by a system of land wires which were not severed by the earthquake. The Japanese radio authorities consider both the transmitting and receiving set as a unit which is known as the Iwaki plant.

Plans for World Radio Expansion

An Interview with General James G. Harbord

JUST returned from a trip to Europe, where he attended the consortium of international radio companies, General James G. Harbord, President of the Radio Corporation of America has authorized RADIO WORLD to publish the following interview dealing with various world radio projects.

The countries represented at this conference in London last month were the United States, Great Britain, France and Germany, and the chief object of the sessions was to complete plans for a projected radio communication service connecting both the United States and Europe directly with South America.

"These plans," said General Harbord, "previously conceived to link the United States and European countries directly with Brazil and the Argentine were enlarged upon at the recent conference. Circuits will extend from the high power station at St. Asise, France; Nauen, Germany, and Carnavon, Wales, direct to Buenos Aires, while the other will bridge the gap between New York City and Buenos Aires through the intermediary of Radio Central, the Radio Corporation of America station on Long Island. The definite intentions manifested by the American, English, French and German radio interests (better known as the AEFG group) at the recent meetings to go forward with the plans which were agreed upon are sufficient proof that the huge program will be brought to a speedy conclusion.

"Reception in Argentina from France and the United States has already been established and the receiving apparatus has been in test operation at Buenos Aires for a number of months. A notable test of this 6,000-mile circuit occurred when the returns of the recent Firpo-Willard boxing contest were transmitted from the giant station at Rocky Point, Long Island, direct to the receiving station at Buenos Aires from which they were subsequently broadcast by radio telephone on a short wave length. Having thus accomplished reception in the Argentine," continued General Harbord, "we are now finishing the erection of a high power transmitting station at that point, which, when completed, will enable us to carry on two-way communications. It is expected that the new service will be ready for commercial use some time this fall.

"It should be of interest to American business to know that a keen sense of appreciation is being evidenced in these developments by business men in South America whose trade intercourse with the United States and foreign countries will be materially enhanced by the establishment of this direct and swift communication service."

When asked about the status of radio broadcasting across the seas, General Harbord had this to say:

"I feel that Americans generally do not appreciate the great strides we have made in radio broadcasting in this country. Certainly the initiative and enterprise which American manufacturers have shown so far have placed this country far in advance of others in this new art. And the great privilege of free broadcasting exists nowhere as we know it in the United States.

"During my visit in France I had the opportunity to manipulate a French broadcast receiver and listen-in to a program broadcast from the Eiffel Tower. The complicated apparatus used for this reception was a striking contrast to the efficient receivers of simplified control that we have in this country at present.

"It will be of interest to note, however, that France is using her high power radio station at Bordeaux to broadcast daily telegraphic press reports which are received by telegraphers at many distant points. So effective is this transmission that press of the day is frequently picked up by a station at Saigon, in Indo-China, some 6,000 miles distant, as well as at Buenos Aires, over 8,000 miles from Bordeaux."

When asked if he wished to interpret the recent radio developments between his company and the Chinese Government in the light of their meaning to America, General Harbord said: "Perhaps we had better begin at the start of these negotiations back in 1921, when the Chinese Government granted the Federal Telegraph Company an independent contract to erect five radio stations in various provinces of China for communication with America. Since that time, the Federal Telegraph Company of Delaware has been formed which incorporates the Chinese radio interests of the Federal Telegraph Company and the Radio Corporation of America, and in which the two American companies will participate jointly under the assignment of the 1921 contract recently approved by China.

"This undertaking calls for the erection of five powerful stations in China, the principal one to be located at Shanghai. This station will engage in direct communication with the RCA stations at Hawaii and even San Francisco, over 5,000 miles distant. Shanghai will also operate a station of lesser power for communication with similar smaller stations to be located at Pekin, Canton and Harbin, each of which cities are separated by approximately 800 miles. In this way the central station of Shanghai will have 'feeder' stations in the principal provinces, through which traffic from these several territories will be routed to the giant station at Shanghai, for transmission to the western hemisphere. Conversely, Shanghai will be the gateway through which communications from points East will pass to the Chinese interior. These stations will be operated jointly by the Federal Telegraph Company of Delaware and the Chinese Government, thus placing the project under Chinese-American administration.

"The confidence of the Chinese Government, in entering into active participation in this program was enhanced largely as a result of the limitation of armament conference held at Washington, D. C., in the fall of 1921.

"There are no exclusive or monopolistic features in this contract," continued the General, "and from the very inception of negotiations the project has had the wholehearted support of the State Department at Washington, who view the recent completion of plans as a signal accomplishment in international diplomacy.

"American business men will be quick to appreciate the commercial significance of this comprehensive plan, inasmuch as there is today only one cable crossing the Pacific to China. And this new, strong link of friendship cannot help but play its own important part in the cause of better understanding between these two countries, and indirectly the peoples of the world."

General Harbord was recently elected President of the China Society, an institution for the promotion of Chinese interests in this country. For this reason, he has a special interest in the contract, from the standpoint of the far reaching business and social influence of the Society.

Work on the stations will begin this fall, and the inauguration of service is expected during the latter part of 1925, although the plan may reach maturity before the time. Test signals will span the Pacific from China well in advance of the official opening, however. A moment spent in glancing at a map of the world reveals that today, although commercial radio is scarcely three years old, we are enveloping the entire globe with radio waves. A further calculation shows that the actual daily transmission range of the high power radio circuits which terminate in the United States totals over 41,000 miles.

A Selective Tuner at a Reasonable Cost

By C. White, Consulting Engineer

THE daily cry is for more selectivity. With the carefully designed modern receivers distance can be easily covered but it is often quite hard to master interference under all conditions. Many amateurs who have built their own single circuit tuners are troubled quite a good deal by interference and jamming. This jamming is noticeable as whistles, groans, and a most varied assortment of howls accompany distant reception. We are apt to blame a good deal of this noise on our neighbors, who operate similar sets and are not well acquainted with tuning to prevent their set from oscillating and awakening the so-called "birdies." To those who already operate a single circuit tuner and do not wish to go to any great expense to change the same I would recommend that they purchase a variable grid leak and a good wave-trap.

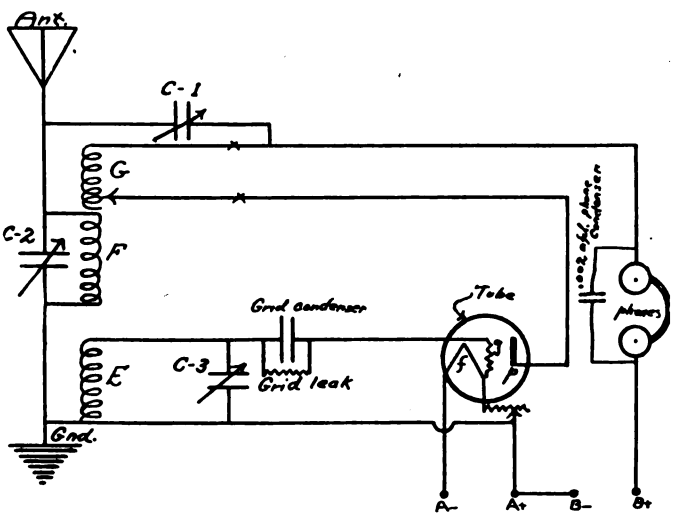
Critical and sharp tuning is quite easily accomplished with this new style of tuner, and still the chief disadvantage of some of the present selective regenerative tuners is completely removed. It is most desirable in tuning in that a receiver should tune rather broad to let you get the range of the station and then be capable of getting more critical adjustment afterwards. With most variable coupling tuners this is readily accomplished by the expert tuner but rather difficult for the average fan to use with success.

Therefore, in this new receiver I have made the coupling fixed and by correct prescribed manipulation of the three variable condensers any degree of regeneration and sharpness of tuning can be had. For instance, let us assume you are endeavoring to pick up a certain station but you do not know exactly where it comes in on the dials. Then you would set the condensers C-1 and C-2 so that they would have a minimum amount of capacity, that is, the dials should read zero if they are correctly set on the condenser shafts. Now the station can be picked up if its signal is of fair strength by adjusting the secondary tuning condenser C-3. If no results are obtained then C-1 can be given greater capacity which will allow more regeneration and the tuning of C-3 can be repeated. It is generally possible to use the condenser C-1 to hold the tube on the point of oscillating by manipulating C-3 and C-1 at the same time.

After the signal has been picked up then the condenser C-2 will come into play. This condenser is used to make the signals much sharper. But as C-2 is tuned in then the capacity of the condenser C-1 will have to be reduced in order to prevent the tube from "spilling over." This is necessary because as the circuit formed by the coil F and the condenser C-2 become tuned to the same wavelength as the circuit E and C-3 the electrical coupling between the coils E and G will be increased very strongly, which means more feed-back action or regeneration. The taps on the coil G will also afford another method to control this amount of regeneration both in the preliminary and final tuning methods. It is plain to see that there are many ways of tuning in this outfit, hence affording plenty of room for experimentation. I personally would not have a receiver that would not allow flexibility in tuning, because you can always have an alternative when the signal is weak with one adjustment to try one of the other combinations of controls.

The constants for the receiver are as follows: The condensers C-1, C-2, and C-3 are each 11 plate variable condensers, although it is preferable to have some sort of vernier adjustment on the condenser C-3 to get exceeding fine adjustment on all wavelengths. The grid leak and the grid leak condenser should be of the correct size recommended by the tube manufacturer, but it is being proven that a variable grid leak resistance is just the thing to use since it affords many critical adjustments. If you are just building your first receiver it would not be a bad idea to purchase a variable leak having the correct ranges and a fixed grid leak. Try both and note the difference between the variable leak adjusted to a certain value and the fixed leak.

A grid leak costs very little at the most compared to the total cost of the receiver, so you might as well get the very best to start with and avoid much of the trouble a bad unit will cause. The next step is to purchase about ten inches of good insulation tubing having a diameter of three and a half inches or thereabouts. All the inductance coils are to be wound with No. 22 S. C. C. magnet wire. The coils E and F each have 60 turns of wire untapped while the coil G has 60 turns tapped for switchpoints at every



A selective tuner easily constructed at home, and at a reasonable cost. Follow the diagram and description exactly in every detail if success is wanted.

fifteenth turn. All the coils should be wound on the same tubing turning the wire in the same direction of rotation, and arranging the sequence of end turn terminals and taps as illustrated. After the tube has been prepared so as to form the complete unit E, F and G, then the surface of the windings can be thinly coated with cement so as to weather proof them and hold them firm. If you cannot obtain cement hot paraffine will serve just as well, but you must take care to scrape off all the excess paraffine.

Of course the general rule of cleanliness in workmanship is paramount in assembling this receiver. Plan your panel layout with precision and care, and make it a point to avoid unusually long connecting wires. After you have built the set try reversing the terminals to the coil G at the points marked X X and note which connection gives you the maximum volume both in the final and the preliminary tuning adjustments. There is one connection that is decidedly better than the other, so you will experience no difficulty in hastily arriving at the correct conclusion. You do not have to shield this receiver unless you care to as an extra refinement. If you do, do not place shielding other than around the vicinity of the three condensers. In order to cut down body capacity see to it that you have the variable condensers connected as recommended. The movable plates or rotors of the condensers C-2 and C-3 should be connected up to the ground side of the circuit while the rotor of C-1 should be connected to the Ant. This receiver will operate well with the new UV199 or C299 tube, affording the correct amount of regenerative control so necessary with a high vacuum tube.

Adding Audio-Frequency Amplification to the Nite Owl Specials

By J. E. Anderson, M. A.

THE circuits published in RADIO WORLD for July 7 and 21 under the title of Nite Owl Specials have aroused considerable interest, if the number of favorable reports and requests for extensions that have been received are to be taken as an indication. Some trouble with the circuits has also been reported from a number of experimenters, but fortunately the trouble reported by one has just contradicted that reported by another, showing that the difficulty does not reside in the principle of the circuit, but rather with the individual application of it. Some say that the circuit will not oscillate at all, and others that it is impossible to prevent oscillations. A warning was sounded in the original article against trouble of this nature and a remedy suggested. Other suggestions will be given below in connection with the circuits having audio-frequency extensions.

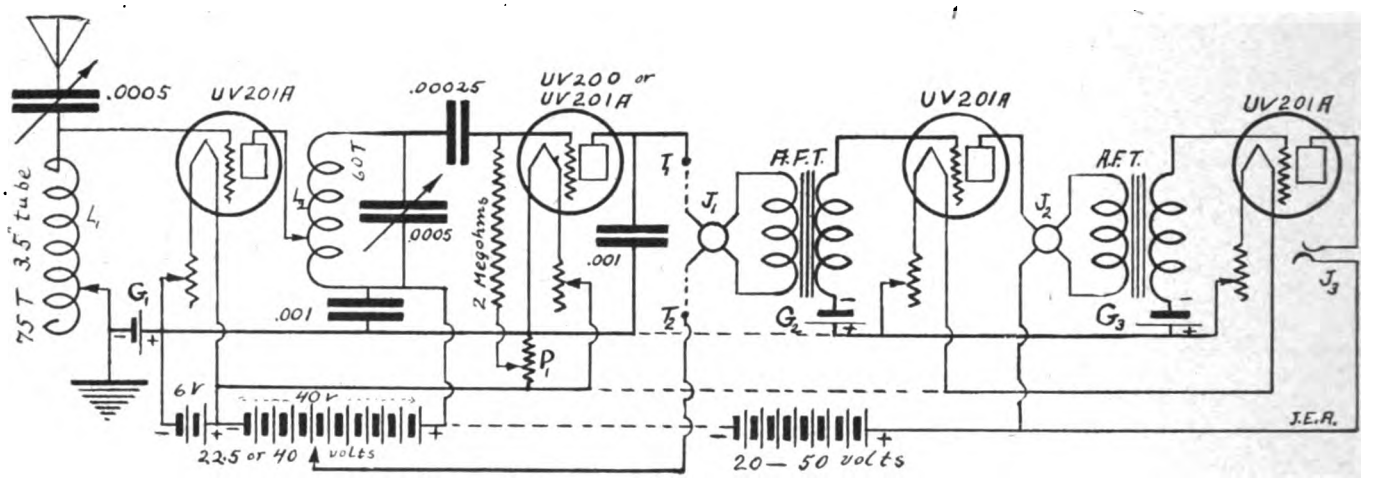

Fig. 1—The original Nite Owl Special with the addition of two stages of audio-frequency. Note the "C" batteries and their position.

Requests have been made for circuit diagrams showing the addition of two stages of audio-frequency amplification to the direct circuit which appeared in RADIO WORLD July 7, and diagrams showing the addition of one stage of audio-frequency amplification to the reflex circuit that appeared July 21. Accordingly, herewith are given the requested circuits, Fig. 1 referring to the direct and Fig. 2 to the reflex.

These two circuits give approximately the same quantity of output, but differ greatly in selectivity. The single circuit, of course, gives greater volume but is not nearly so selective as the other. If desired, the single circuit may be made the reflex and vice versa.

In order to help prospective constructors, all the electrical constants of the various component parts are given. The design of the circuit has been made especially for use with UV201A tubes as amplifiers and either a UV201A or a UV200 tube as detector. If a UV200 tube is used the potentiometer should be connected as shown; if a UV201A is used the lower end of the grid leak may be connected permanently to the positive side of the "A" battery and the potentiometer either dispensed with or used as a stabilizer in the grid circuit of the first, or radio-frequency amplifier, tube. In that case the positive side of the first grid battery should be connected to the sliding contact of the potentiometer instead of to the negative side of the "A" battery. For the UV201A tubes the filament rheostat may be any six ohm rheostat on the market, but for the UV200 it should either be a carbon pile rheostat, or one furnished with vernier adjustment. The grid condenser of the detector is given as .00025 mfd., but it may have any value down to .0001 mfd. It is essential, however, that its insulation be of the highest. Either air or mica dielectric is recommended.

The symbols J_1 and J_2 represent double circuit jacks. These are rather unconventional, but are drawn that way for convenience. J_3 is a single circuit jack for the telephone or the loud speaker. T_1 and T_2 are the telephone terminals of the original circuits. The dotted lines represent the necessary leads to the added audio-frequency amplifier. If the original circuits and the amplifier are built in separate units, the dotted lines would represent the connecting straps from one cabinet to the other.

The "B" battery voltage on the UV200 detector tube may be any value from 16.5 to 22.5 volts. The correct, or optimum, value can best be found experimentally. If a UV201A is used as a detector the plate potential should be 40 volts. The plate voltage on the radio-frequency amplifier tube in Fig. 1 should also be about 40 volts. In Fig. 2 it would be better to use 60 volts on the first tube, although only 40 is shown, in order to prevent distortion of the audio-frequency load on that tube. For the same reason the plate voltage on the other audio-frequency amplifier tubes should not be less than 60 volts and may be as high as 90. Good quality cannot be expected for low plate voltages if the volume of the signal is sufficient to operate a loud speaker.

The proper grid biasing batteries G_1, G_2, G_3 depends entirely on the plate potential. If the plate potential is 40 volts, the proper value of the grid biasing voltage is about 1.5; if the plate potential is 60, the proper grid bias is about three volts; if it is 90, the grid bias is either 4.5 or six. On the first tube in Fig. 1 the question of grid bias is not of much importance, as a deviation from the correct amount merely reduces the amplification; but on the audio-frequency amplifiers it is important, as a deviation not only reduces the amplification, but increases distortion.

Digitized by Google

Although these circuits have been designed for use with UV201A, other tubes may be used. UV201 may be used to good advantage if the necessary storage battery for heating the filament is available. Even the dry cell tubes, such as WD11 and UV199, may be used if the output is limited to that which one may listen to with comfort with an ordinary headset. No particular changes need be made in the circuit except in the voltage of the "A" battery. If UV199 tubes are used the voltage of the filament battery should not be greater than three volts. The customary voltage of 4.5 for these tubes requires 30 ohm rheostats, whereas the rheostats in these circuits have only six ohms. However, a resistance of from 10 to 20 ohms may be inserted in series with the battery somewhere in order to get around this difficulty.

If either UV201A or WD11 are used throughout, the total current consumption will be one ampere; if UV199 tubes are used throughout, the current will only be .24; but if UV201 and UV200 are used, the tota! current will be four amperes. Hence for the latter tubes storage batteries will be required, while for all the others it is possible to use only dry cells. For the UV201A and WD11 there should be as many dry cells in parallel as there are tubes in parallel, since the normal discharge current of a dry cell is one-fourth ampere. If a UV200 detector tube is used together with three UV201A the total current will be 1.75 amperes. Hence a storage battery will be required for this combination. The extra volume obtained by virtue of the greater sensitivity as a detector of the UV200 than the UV201A is not worth while in view of the great increase in the heating current.

If oscillations cannot be prevented by means already discussed, it will be necessary to use resistance. The use of the potentiometer has already been suggested for this purpose. A plain resistance of from 100 to 500 ohms may be inserted in series with the grid or plate circuits. If in the grid circuit it should be put near the "A" battery; that is, between the negative of the "A" and the positive of the "C," or grid battery G_1. If in the plate circuit it may be put in series with the plate lead. This, however, is not so good as the other connection. The oscillations may also be stopped by reducing the plate potential or the filament current, or by changing the grid potential of the tube. But these methods are not practical for any of the tubes carrying audio-frequency currents. The use of a potentiometer of about 400 ohms is probably the best for both the circuits given herewith.

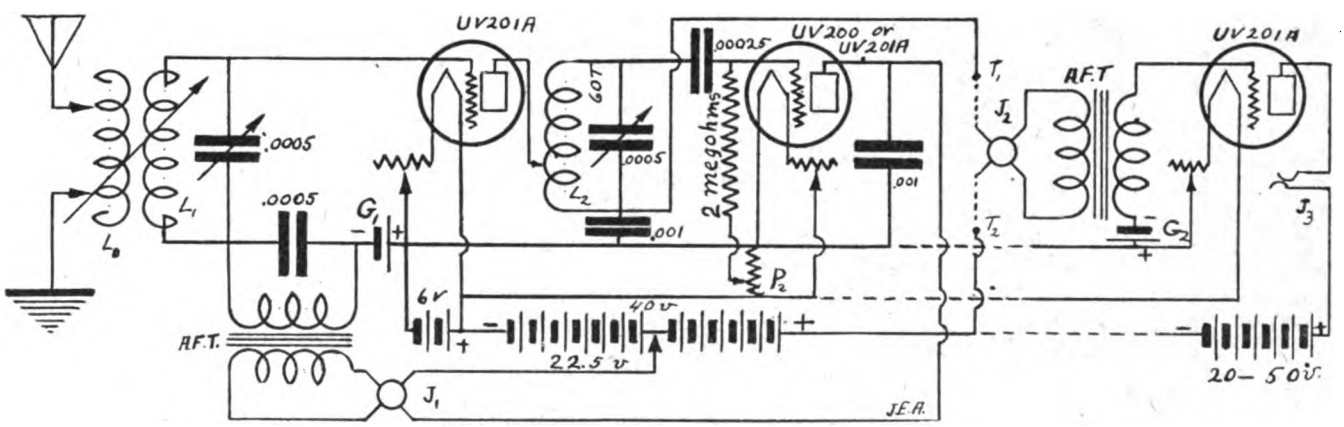

Fig. 2—Improved Nite Owl reflex with the addition of audio-frequency. Extreme care should be taken in the wiring to prevent howling due to intercoupling.

Changes in Broadcasters

ONE new limited commercial broadcasting station was licensed last week:

Call	Station	Class	Frequency Kcys	Wave Length Meters	Power Watts
KUY	Coast Radio Co., El Monte, Cal....	A	1170	256	50

The following limited commercial broadcasting, Class A station, was licensed on June 2, 1923, but was omitted from the weekly list:

KFJB	Marshall Electric Co., Inc., Marshalltown, Iowa..		1210	248	10

Eleven limited commercial broadcasting stations deleted during the month of August, 1923, were as follows:

Call	
	Class "A"
WEAD	Henry Radio & Elect. Supply, Atwood, Kans.
WSAQ	Round Hills Radio Corp., Dartmouth, Mass.
KFIJ	Therean, Sidney I., Platte, S. D.
	Class "B"
WGM	Atlanta Constitution, Atlanta, Ga.
	Class "C"
KGO	Altadena Radio Laboratory, Altadena, Calif.
WRP	Federal Institute of Radio Telegraphy, Camden, N. J.
WJAP	Kelly-Duluth Co., Duluth, Minn.
KGB	Mullin's Elect. Co., Wm. A., Tacoma, Wash.
WLAY	Northern Commercial Co. of Alaska, Fairbanks, Alaska.
WJAK	White Radio Laboratory, Stockdale, Ohio.
WQAY	Gaston Music & Furniture Co., Hastings, Neb.

Use Standard Goods

MANY amateur builders when considering the making of a new set think first of the cut-rate shops where lots of cheap goods can be purchased. They do not consider the protection afforded by a standardized label or carton on the goods they buy. If they would only think of the protection a standard piece of goods made in a large factory, tested and sold at a standard price affords them, they would not buy the cheap apparatus that has no name, or else some funny name closely approximating the real goods.

RADIO PRIMER—For the New Army of Radio Beginners

By Lynn Brooks

PREPARATION FOR FALL RESUMPTION:—Now that the summer season is practically over and the fans are paying more attention to radio than they did, certain little details will be attended to by the amateur who knows and who expects to get maximum results out of his set.

First and foremost, examine the antenna. Take it down and clean the insulators thoroughly with good soap and water to remove any dust or dirt that may have accumulated through the hot weather. Examine the connections, especially the lead-in, and make sure that it is still making good contact. If there are any splices made in the wire, make sure that they are clean and making perfect electrical contact. If you have not soldered your antenna connections before, now is the time to do it. Scrap the wire and make a sure soldered connection.

Then examine the ground lead and see that it is perfect. Make a thorough job of the inspection and do not simply glance at it. If the ground clamp is fastened to the water pipe it is best to remove the clamp and re-scrape the pipe and the clamp.

The next thing of importance is the renewal of the batteries. Renew your B batteries. On their face they do not show their condition and there is no way they can be tested except by the use of a voltmeter. A 22½ volt battery should not be used when its voltage drops below 15 and a 45 should not be used when its voltage drops below 30. Do not make the mistake of connecting new batteries in the circuit with old ones. The old ones will act as a drag on the new ones, absorb the current from them and seriously hurt their life. Therefore get new ones that have their shelf life marked in plain figures on the side. If storage batteries are used to furnish the current for the plate circuit, keep them thoroughly charged and their plates covered with the solution.

In the case of the storage batteries used for filament current see that the connectors are clean and that a small amount of vaseline is spread lightly over the surface. If the storage battery has been in use more than a year, take it to a service station and have it looked over to determine if it needs cleaning. It probably will and should be cleaned by an expert. Do not attempt it yourself unless you understand storage batteries thoroughly.

The next important thing is cleaning the set itself. Remove the tubes from the sockets, remove all the connections and take the set where there is a good light. Then with a fine brush and a rubber tube blow and brush all the dust out of the corners and rub all the dust off the surface of the apparatus, not forgetting the corners. Do not go about it vigorously, but take it easy and at the same time make sure that you get all the dust and dirt out. Even though the top may be closed all year round, a lot of dust and dirt will accumulate in corners, between wires, and in fact every place in the set that it can. It should be cleaned thoroughly.

The next thing of importance is to see that all your switch arms are making good contact. The points will generally corrode a bit. Go over them with a little wood alcohol on a rag and wipe the surface of all moving contacts with it. Make sure that none gets on any of the apparatus.

Then examine the lugs of your tubes. The little lead nipples should be brightened by lightly passing a piece of emery paper or emery cloth over them. Then examine the contacts on the tube socket and see that they have not lost any of their tension and still press against the tubes.

When you are sure that you have chased all the dirt out of your set, re-hook the batteries, making sure of the connections, and your set is again ready for another winter of DX. This fall house cleaning is important and should be attended to before you have trouble and go hunting. A little care now will save lots of time and trouble later.

DX on Crystal Receivers

By Paul Thorne

THE letter of Philip Keansby, in RADIO WORLD for August 25, again brings up the subject of DX on crystal receivers. Let me settle this question, which seems to rage pro and con without end.

A neighbor and myself conducted experiments along this line recently. He operated a three-tube set, while I used a very good crystal set which I keep as a sort of "life boat" for emergencies. This set has never been able to pick up anything outside of Chicago except WCBD at Zion, which came in very faint.

During this experiment, by pre-arrangement, he would pick up certain distant stations, and I would tune my crystal to that wave length. He picked up a number of stations, the most distant being Troy, N. Y. In every case I heard the concert distinct and loud while he held it tuned in. When he tuned out, I lost all signals.

During this test I particularly noted that I could hear every move he made, my crystal set responding to his tube set just as if my phones had been connected direct to his set. I also noticed that I got the best results when I was tuned to the exact wave length of the station he held.

I consider that this test absolutely settles the whole question. When a crystal owner gets DX, let him inquire among his tube set neighbors, and he will find some one who had the station at the exact moment.

There were many interesting details connected with this test, but I am taking space only to give the results. As we are both well out of the amateur stage and thoroughly understand what we are doing, we are convinced that we have definitely settled this question of whether or not a crystal can get DX and whether or not a tube set transmits to a nearby crystal receiver.

A Remarkable DX Circuit

By H. S. Potter

THIS seems to be a day and age of new circuits, and everywhere we turn we are stared in the face by radio publications telling, in glaring headlines, of some present-day Marconi who has revolutionized radio by discovering some new principle, which he does not intend to patent, but will give to the world.

I do not claim that the circuit which I am showing here will enable any person who has no knowledge of radio to hear the English broadcasting stations on one bulb, or to fill a room with music from the stations on the West Coast. It is a regenerative circuit and a very good one, the best I have tried for broadcast receptions, as well as being a whiz on short wave C. W.

I hit upon this hook-up while I was experimenting with some of the old favorites. As it was remarkably good, I felt that it was worthy of public attention.

My claims for this circuit are remarkable sensitivity, fine tuning, and entire lack of distortion. As in all regenerative circuits, it is necessary to add two steps of audio-frequency amplification if sufficient volume for a loud speaker is required. On one tube I have found the volume to be slightly greater than on the standard two-variometer and variocoupler set.

I will give all information necessary for building a set from this hook-up, but will omit panel dimensions and layout, as every ian has ideas of his own as to the proper arrangement of his apparatus, and will adapt his panel dimensions to the available location for his set, or to a cabinet easily procurable. As a hit, I would suggest a standard 7"x18"x3/16" Formica panel.

In the sketch, L-1 and L-2 are the primary and secondary, respectively, of a variocoupler. This may be of any good make, having a tapped primary. In selecting a coupler, pick one which is wound with fairly heavy wire, about No. 22 or No. 24, not the ultra compact ones using very fine wire, about No. 28 or No. 30. See that the windings are not thickly coated with shellac or varnish, as this greatly lowers the efficiency of the instrument, due to creating a high distributed capacity. Some gain in efficiency is also obtained by using an instrument having very thin walls to the winding form, but this feature should not be carried out at a sacrifice of rigidity.

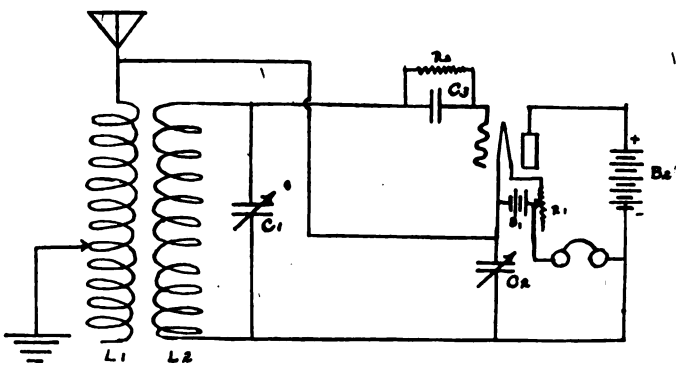
The secondary circuit is tuned by a variable condenser, C-1. This has a maximum capacity of .0005 mfd., which usually means 23 plates, and should be of the built-in vernier type, as the tuning is very sharp.

Condenser C-2 controls regeneration. It is of .001 mfd. capacity, and has about 43 plates. No vernier is required, but a vernier condenser may be used if the builder so desires, and will perhaps help a bit on distant reception.

Right here a word on the selection of variable condensers might be in order. Do not waste time and money on the cheap, worthless pieces of junk sold for 75c to a dollar. A good condenser should have rigidly spaced plates and pigtail connections to the movable plates. There should be enough clearance between plates so that a slight jar will not cause the plates to touch, causing a short circuit. Do not buy a condenser with end plates of moulded "mud," or of dull, cardboard-like fibre, as these compounds usually allow a high leakage. Bakelite, Formica, or Condensite end plates are best, provided metal bearings are provided for the shaft to run in. Be sure the shaft is of standard diameter, as many of the cheap condensers now on the market will not take a dial of standard ¼" bore. As a matter of neatness, it is well to pick condensers whose mounting screws will go under the dial, on the face of the panel. Most of them are built this way at the present time, so this feature should not cause much delay in selecting your instruments.

Little need be said of the grid condenser, C-3, and the leak, R-2. They will have a value of about .0005 mfd. and one megohm, respectively, but this may vary with the type of tube used. R-2 may be made adjustable to advantage. Do not use one of the paper grid condensers, sold for a dime, in position C-3. The only type which is worth while is the mica type, and these are cheap enough to make their use well worth while.

The resistance of the rheostat, R-1, will vary with the type of tube used, as will the voltage of the battery, B-1. The battery, B-2, will be of about 22½ volts for most of the detector tubes now on the market, although it is well to use a tapped B battery, so that the proper voltages may be obtained. On some tubes an even



Circuit diagram of a remarkably selective receiver which is easily controlled and reasonable to construct.

higher voltage than 22½ is an advantage, but this may be determined by experiment on the individual tube in question.

We have, at the present time, a great variety of tubes to choose from. Do not be foolish, and waste time on any of the many unlicensed tubes, or "bootlegs," now on the market, as they are entirely worthless. This includes the many "French" and "Dutch" tubes, most of which are fakes.

Of the good, licensed tubes we have, first of all, the old reliable UV200 or C300. This fits in a standard base, and operates from a six-volt storage battery for filament lighting, with a six-ohm rheostat in series. The main objection to this tube for broadcast reception is the necessity of a bulky storage battery.

Of the dry cell type of tubes, we have the WD11, the WD12, and the UV199. Of these, the first two named have the same electrical characteristics. They operate on one dry cell for filament lighting, and draw .25 ampere. The WD12 is somewhat more desirable, as it fits in a standard six-volt tube socket, while the WD11 requires a special one.

The type UV199 is also a good detector. It has a special base, is the smallest radiotron tube, and is well suited to use in a portable set. This tube operates on three dry cells in series with a 30-ohm rheostat. The voltage drop across the filament is three volts, and the filament current is .06 amperes. Due to its low filament current, a UV199 can be operated from a large three-

How the Drama Readily Lends Itself to Radio Broadcasting

By Martin P. Rice

Director of Broadcasting, General Electric Company

DRAMA, as a literary form, lends itself at once to radio broadcasting. The actor's finest interpretation of a part is faithfully transmitted to the ears of a great audience without the loss of a syllable or the blurring of an inflection, and under conditions that enable the listeners to concentrate their entire attention on the spoken lines.

Drama, however, carries the inherent suggestion of action, and the question, "How can action be broadcast?" is promptly presented. Before attempting to answer it, we should consider the essentials of dramatic art.

In common with all other fine arts, the drama consists not in a mere reproduction of nature but in an orderly arrangement of certain factors chosen because of their pleasing or appealing qualities. Supplementing these elements in the presentation of dramatic art, stage settings in the modern theatre appear to have reached their maximum development. In fact, it is a question whether they have not in some cases been so heavily emphasized that they overshadow the dramatic interest rather than contribute to it.

The early drama was produced with little or no scenery and without the present-day wealth of costume. The addition of scenery limits the action and at the same time restricts the imagination by confronting it with rigidly defined forms. Perhaps it is on this account that one derives more pleasure from the reading of a Shakespearean drama than from an indifferent performance with elaborate scenery.

In the absence of such conventional forms, the play of the imagination meets no barriers save those erected by the individual's own personality—his own power to comprehend and appreciate. His imagination is capable of unlimited expansion; it envisages the finest subtlety, the deepest sadness, or the highest joy. This fact is recognized by authors who instead of describing a scene or an action in every detail, leave it to be completed by the imagination. Here radio broadcasting enters a dramatic field in which it can attain unique prominence.

Radio drama has the subtle power of staging or suggesting action without being under the necessity of actually reproducing it. So long as there is an ear to hear and an imagination to construct and color, there are no scenic limitations to the radio play and very few as to action. Deftly written lines can carry the listener across the wilderness and overseas, through torrential rains and to the frozen North, into deep mines and on the wings of speeding aircraft. Every mechanical device for imitating sounds is at the disposal of the radio dramatist—the midnight stroke of a great clock, the roar of a waterfall, the moan of wind, and a stealthy step in the dark. Situations impossible of presentation on an actual stage are conjured before the listener's mind in a single phrase.

Small wonder then, that radio is developing an entirely new type of play, almost as free of limitations as is life itself! Small wonder if a new type of actor finds in it opportunity for new forms of artistic expression! Swept of conventional properties and scenery, the radio stage is as wide as the world, as free in its permitted action as the whole range of human experience. If it makes no appeal to the eye, it falls the more intimately on the finer perception of the mind; if it must enlist the imagination, it carries an emotional thrill to which only the imagination can respond.

In all these aspects, the radio drama is a direct contrast to the motion picture, which makes its chief appeal to the eye. The "screened drama" is, of course, devoid of literary form. It is, in essence, merely a sequence of events. While it is capable of reproducing dramatic action very much as the pantomime reproduced it in years gone by, it is in favor today chiefly as a means of visualizing novels or producing plays that have achieved greatness in some other form—of showing events which dramatic art has formerly clothed in literary garb or produced on the stage of the theatre.

We are present at the birth of a new form of literary expression. The radio dramatist, unhampered by the restrictions of the theatre and with an immense audience of sympathetic and attentive listeners, has only to enter his kingdom. The possibilities which have been outlined are alike his opportunity and his inspiration. In the adaptation of existing plays to radio at WGY, the General Electric Company's broadcasting station at Schenectady, N. Y., a torch has been lighted over this new path of literary creation. Here a little company of earnest men and women, wise in stagecraft, are shaping the expression of the new art and establishing its technique. The possibilities of drama and of comedy are being weighed and the results broadcast to the world.

We are only at the beginning of these things, but that beginning is rich in promise—the promise of an art that shall contribute mightily to the cause of culture and more especially to the appreciation of fine dramatic expression.

(Concluded from preceding page)

cell flashlight battery, if weight and bulk must be reduced, but this is not desirable, as these batteries will not stand up long on continuous duty.

Many an otherwise good tube is a failure, due to the use of a cheap and entirely worthless tube base. All of the very cheap ones have either poor contacts or high leakage between terminals. Get one whose insulating material is Bakelite or Formica, and not of some cheap moulded material, or of low grade fibre.

I am quite sure that any experimenter who tries out this circuit will be well pleased, if he observes a few simple precautions, as mentioned above. Do not use inferior parts, and then blame the circuit if you are disappointed.

Now a word to you fellows who try this circuit: If your results are exceptionally good, won't you help the game along by letting the gang know of it, through the columns of RADIO WORLD? Go to it, men, and the best of luck!

An Easily Built Super-Regenerative Set

By Byrt C. Caldwell

THE great majority of the radio public has kept away from the super-regenerative circuit as though it was a circuit for only Marconis and Armstrongs to experiment with. No impression could be further from the truth. Amateurs and broadcast fans by the hundreds have proven that if reasonable care and judgment is used in the selection of instruments, and in the building of the set, little trouble will be encountered. The super-regenerative set should really be adopted by

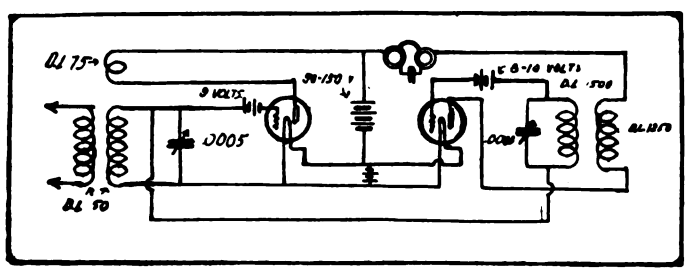

Fig. 1. Circuit diagram of an easily constructed super-regenerative set.

more. It is the nearest towards the ideal that any circuit has reached, with the possible exception of the reflex. The super is easier to construct and adjust than is the reflex, and more miles per dollar are obtained with this circuit than with any other. When this set is used with a loop, results equaling a multi-tube regenerative set which uses an outdoor antenna, are obtained and for the reason that a loop is used, radiation is reduced to a minimum.

The diagrams illustrate a two-tube super-regenerative set that was built by the writer. There is less work required to make this set than there is to make a plain regenerative set with one step of amplification.

The diagram shows the arrangement of the instruments. In making this set, all that is required besides the single tube plain regenerative apparatus, is an extra tube, grid batteries, a variable condenser, and the two large inductances. In looking over the diagram, you will see that the set is really very simple.

Honeycomb or duo-lateral coils were used throughout for inductance. The primary is a 50 turn coil, the secondary 50, and the tickler 75. The grid coil is 1500 turns, and the plate coil contains 1250. They are arranged at opposite ends of the base and at right angles to each other. The variable condensers were of the two plate mica-dielectric type. One of them is inverted so as to make room for the tubes, which are placed between them, with the plate of one tube at right angles to the plate of the other. They must both be hard tubes. The new 201A tubes are as good as can be obtained. The grid batteries consist of several three volt flashlight batteries connected in series, the voltage for the first tube being 9, and for the second, 8 to 10. They should be placed on the base as close to the tubes as possible.

The plate battery, for successful operation, must have a high voltage, 90 to 150 being about right. The higher the voltage, the better the results, within certain limits.

The arrangement of the apparatus shown is the best possible for maximum results.

In wiring the set, use bus wire, or other large copper wire, and be sure to solder every connection thoroughly.

No rheostats are used, and this obviously lowers the number of controls and simplifies the operation of the set.

The operation of the receiver seems to have been the reason that the super-regenerative was not taken up. It is really an extremely simple matter to tune the set if you use a little common sense. You will never get results by just twirling the dials aimlessly. The proper method is as follows: After the filaments are lit, there should be a whistle audible in the phones. If this is not present, vary the grid battery of the second tube, and the second condenser, until this whistle is heard. This shows that the second tube is oscillating. After the whistle is heard, adjust the tickler coil and the first condenser to make the first tube oscillate. You can tell when this occurs, by touching the antenna binding post. A loud click will be heard if the tube is oscillating. After both tubes are oscillating, tune the stations in with the first condenser, and

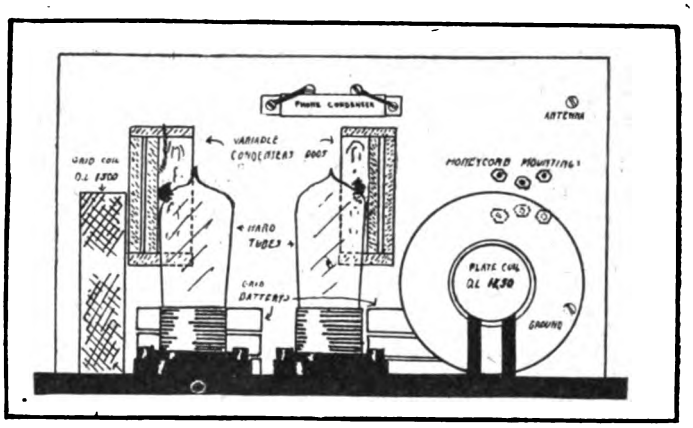

Fig. 2. Suggested location of instruments for efficiency in wiring.

with the honeycomb coils. Then vary the second condenser until maximum amplification without the whistle is obtained.

If a loop is used, it should consist of about 100′ of insulated wire spaced ¼″ between turns and wound on 2′ or 3′ loop.

This receiver will give wonderful results and for the person who is looking for the greatest distance this set is just the thing.

Radio Progress in France

WIRELESS telephony is making marked progress in western France where, through the efforts of dealers, the demand for installations is increasing every month, Consul Fisher reports from Nantes.

Evening concerts are given in Paris by two radio companies and the latest commercial, financial and sporting news is broadcast for interested fans. Cafes, hotels and country homes outside the city limits are said to be especially interested in securing receiving sets.

At Nantes, situated about 250 miles from Paris, most of the receiving stations are equipped with four to six tubes—one high frequency, one detector and two low frequencies, or as Americans would describe it, one radio-frequency, one detector, and two audio-frequency tubes. Double wire antenna about 131 feet long and raised about 23 feet from the ground are popular. Most of the apparatus is of French manufacture, the cost averaging 1,600 francs or approximately $150.

Government taxes on transmitting stations run from 100 francs per year up.

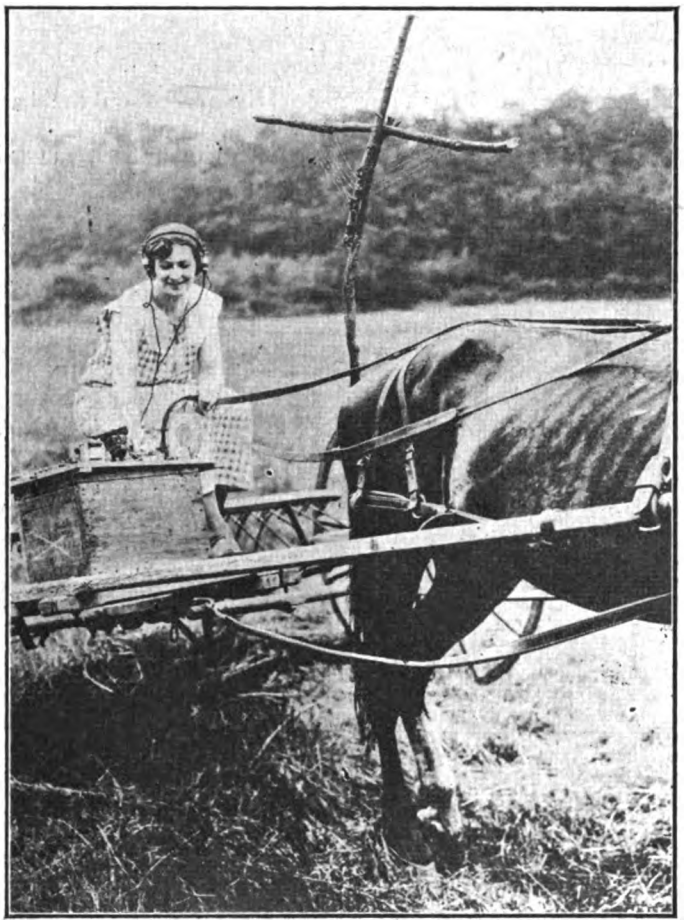
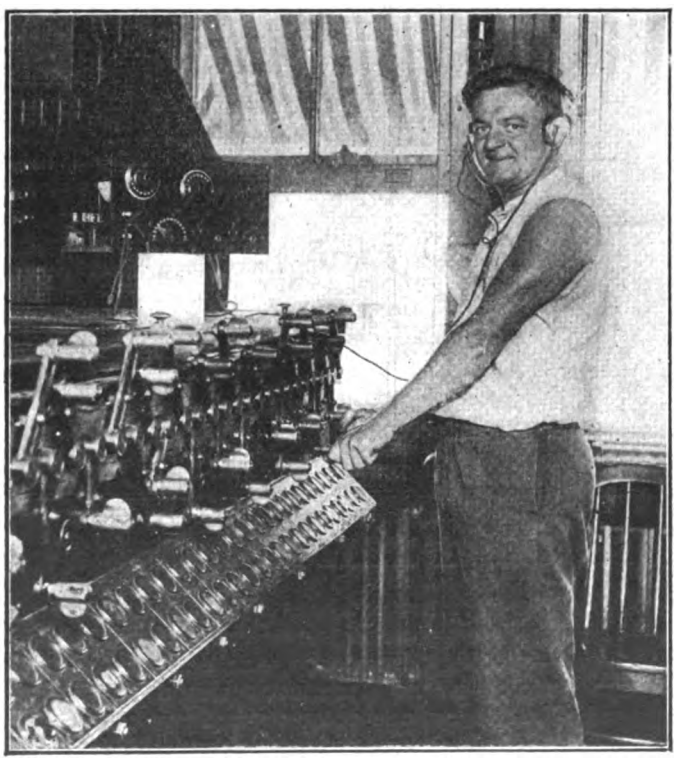
Radio News Pictures Come Piling In—H



(C. Gilliams Service)

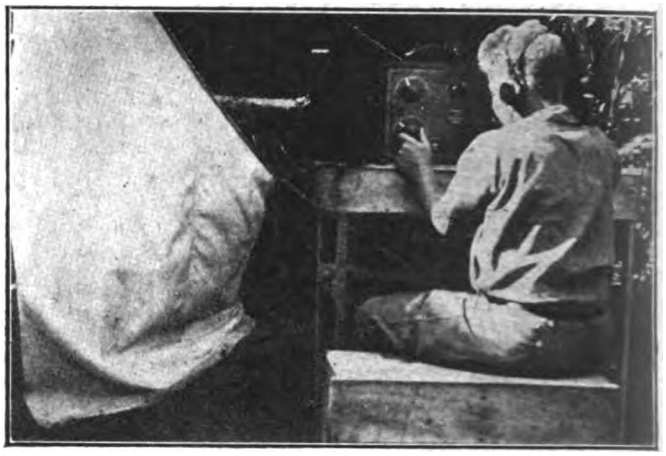
Making hay while the sun shines is not a rite for the farmer alone these days. Mrs. Holt Ramsey, while on her vacation, thought it would be great fun to rake hay if it were not so lonesome. So the farmer's son hooked up a "rustic radio," and now Mrs. Ramsey can make hay while listening to the radio play.



(C. Kadel and Herbert)

Edward Jonckin, signal tower man at the 179th Street elevated station, New York City, has installed the radio set seen over the switchboard and listens in while switching the trains around the tracks. He claims that there is no interference at all due to the trains and high voltage lines, and during the wee hours of the morning when the trains run on half-hour schedule he just clamps on the old "ear muffs" and pulls 'em to the distraction of his mates, who have to while away the weary hours "lookin' sharp."

Most Popular Scout in Camp



(C. Kadel and Herbert)

OF course every Boy Scout camp this summer had at least one radio receiver, and the owner of such apparatus was sure to be the most popular scout, especially when there was a good program on. As the camps were scattered far from the touch of daily newspapers, where the baseball scores and other big games were held, it was always possible to keep right in touch with the sport through the daily broadcasting of the scores.

The illustration shows one of the lucky ones tuning in on his Radiola. Portable sets of this type have probably done more to keep the interest of the average broadcast listener alive during the summer months than any other agency. The fact that they operate on dry cells, take up small space and do not weigh much make it possible to take them anywhere you go. They are rugged and stand traveling well.

The portable sets function just as well as the old-time, cumbersome, storage battery sets, and you have the advantage of knowing that you can always have your radio set with you. The "old-timers" will remember the sets in vogue six or eight years ago when the amateur who had the most "junk" spread over the largest amount of table space and the most complicated switching devices was always considered to be the "real experimenter." Contrast it with the three and five tube sets of today, that copy anything from New York to San Francisco and yet can easily be carried any place you go.

(C. Kadel and Herbert)

Up to the present time radio has never been considered as an instrument of beauty, but rather as a useful instrument to while away the weary hours, or words to that effect. Now along comes Miss Jean Tolley, who has decked out her receiver in ribbons of bright hue and carefully plaited them around her loud speaker, so that they will harmonize with her negligees and boudoir.

Broadcasting Broadway Hits

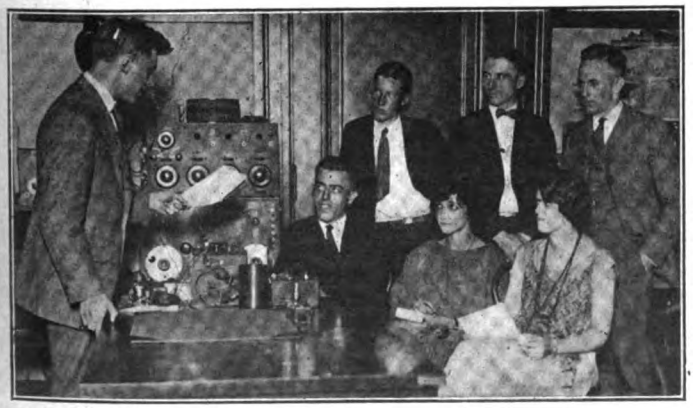
AFTER a few experiments in the broadcasting of popular hits the producers of plays and the broadcasters found such a demand for this type of entertainment that it is done whenever possible.

Of course, the listeners have to have a good imagination to even get a faint idea of what is transpiring at the studio, so, therefore, we are going to let you have a peek "behind the scenes" at a broadcasting station during the performance.

The illustration shows the entertainers of Will Morrissey's "Newcomers," recently broadcast from Station WOR. Because of the fact that local "color" is only necessary on such occasions, it is not necessary to "dress up" unless the actress is extremely temperamental and cannot go through her lines without being in costume.

Even at that, it is impossible to get a thrill out of being told that a certain party is a wonderful dancer. Maybe when we have Wireless Movies—don't laugh—they laughed at the Wright brothers—we may be able to get a peek at the "Premier Danseuse," but until that time we will have to be content with hearing the songs and lines. Even at that, what can be nicer than hearing a show broadcast while sitting home in your comfy chair with the old briar going strong and a nice cool pair of house slippers on—and the ice box near for a "midnight lunch"?

(C. Kadel and Herbert)



(C. Kadel and Herbert)

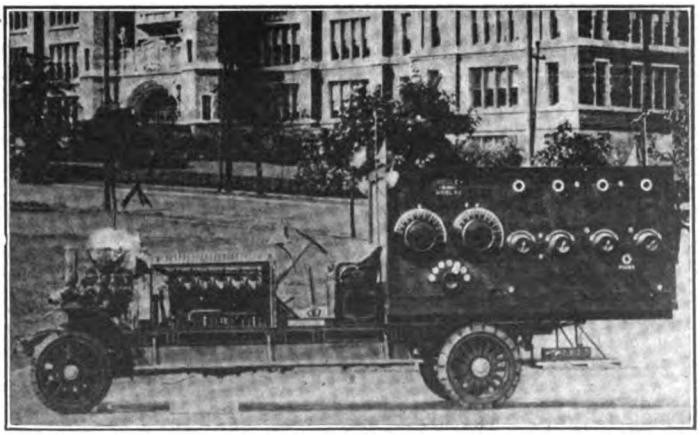
After the amateur successfully passes the test, he has to go in and listen to a talk on how a set should be operated and when and where to keep quiet. The photo shows J. W. Swanson, radio inspector, giving a group of five amateurs (yes, the two ladies want to be classed as amateurs, or O. W.'s on the air), a little talk on the secrecy of messages and the operation of the station during the quiet hours.

(C. Photonews)

W. H. Bullock, a New York radio engineer of note, has invented a novel indoor antenna. Using an ordinary window shade the wires are sewn around the edge. A loop effect is gotten very easily, and it can be tuned by raising or lowering the shade itself.

(C. Kadel and Herbert)

Leo and Helen Eisemann heard daddy talk about "birdies" in sets, so while dad and ma were out for the afternoon they started in to look for the "chippies," and even though they didn't find any, a good time was had by all—until daddy happened to see them and the remains on the lawn. And there was a fight being broadcast that night, which didn't make it any harder for dad to do his duty.



(C. Underwood and Underwood)

Huge receiver mounted on an Ahrens-Fox fire engine chassis, which formed one of the most interesting displays and floats in the Fall Festival parade recently held in Cincinnati. Music was received by means of the small receiver located on the back step under the big set, and the big horn was located in the large model. Music was received from Crosley Station WLW, and broadcast by means of a large horn inside.

Radio Will Guide German-Built Zeppelin to America

By Carl H. Butman

(*Copyright*, 1923)

WASHINGTON, D. C.—Early in November it is expected that the Zeppelin Company will point the nose of the great German-built ZR-3 toward the west and the long over-seas journey of the navy's second airship will begin. On her maiden trip to her American home at Lakehurst, N. J., a distance of approximately 3,600 nautical miles, radio will guide this latest zeppelin.

She will not be under radio-control, as was the old battleship "Iowa" when sunk by naval gunfire, but radio will carry to her twice daily complete forecasts of the weather ahead and the meteorological conditions on the southern trans-Atlantic steamship route along which, it is understood, she will proceed under the direction of the German officers and crew. The only American officer who is certain of making the trip over is Capt. G. W. Steele, U. S. N., her future commander, but it is possible that Cmdr. Garland Fulton, Lt.-Cmdr. S. N. Kraus and Lieut. R. G. Pennoyer, naval observers now at Friedrichshafen, may also be among the passengers.

Briefly the characteristics of the new aerial passenger cruiser (she is not a war craft, at least not yet) are: length 660 feet, slightly less than the American-built ZR-1; diameter, 90 feet; power, four 400-HP Maybach engines, giving a speed of approximately 80 miles per hour. In one sentence, she is the last word in old-world airships and it will be interesting to witness a comparison and test with the new world's ZR-1, with which ship she will share the gigantic double hangar at the Lakehurst Naval Air Station.

Although the United States has no control over this craft during her flight over the Atlantic, nor, in fact, until she is officially delivered to the navy as a reparation ship, the government is to co-operate in "paving the way" on her first cruise. Through arrangements between the Weather Bureau, Navy, Shipping Board vessels and certain other North Atlantic ships, meteorological data from all along her route will be compiled and radioed twice a day to a station ship in mid-Atlantic. This vessel will have a powerful radio set and will transmit to NAA, Arlington, Va., bulletins for broadcasting to the ZR-3, both before and during her flight.

All details have been arranged between the Navy and the Weather Bureau. The plan includes the receipt of storm warnings, forecasts and statements of weather both at sea and ashore which might in any way affect the passage of the great airship. Observations will start a full week before the craft leaves Germany, and the reports will be on the air until she is housed in her hangar.

Little is known of the radio equipment of the ZR-3, but it is said that it is also of the latest German radio design, and that transmission and reception is assured all the way across the Atlantic, although half that range would be sufficient due to the co-operation of the station ship and station NAA.

WORLD NEWS HAPPENINGS BRIEFLY PHRASED FOR OUR BUSY READERS

What do you radio, good cheer or the reverse?—Forbes Magazine.

* * *

The new radio station at Coltano, Italy, has been assigned the call ICC and operates on 10,750 meters. Station PCG is the call for the new station at The Hague, Holland, which uses a wave length of 12,500 meters.

* * *

Eastern radio fans have been invited to the World's Dairy Congress, by H. E. Van Norman, president of the congress, who spoke from the Westinghouse transmitting station, KDKA, Pittsburgh, Pa. The congress will hold sessions at Washington, D. C., on October 2 and 3; at Philadelphia, Pa., on October 4; and at Syracuse, N. Y.

* * *

Radio was enlisted last week in the search for William P. Massing, of Washington, D. C., whose father and mother were killed when a train struck their automobile at Crawfordsville, Ind., their home. Massing left Washington two weeks ago to travel through New England in an automobile on a vacation trip and had not heard of the accident.

* * *

The latest discovery reported from the research laboratories of the Western Electric Company is a solution of the mystery of singing oscillations noticed in radio receivers. One of the engineers by chance dissected a worn out "B" battery and found the cells wrapped in scrap sheet music. He claims that the notes so jazzed the electrons as to make them sing. He'd better destroy all evidence at once—the American Society of Music, etc., will be after him for back royalties.

E. F. W. Alexanderson, chief engineer of the Radio Corporation of America, is enjoying a trip in Europe and will return about October 15.

* * *

The General Electric Company has representatives at Caracas, Mexico, who are preparing a contract for the construction of a large radio transmitting station there, it is understood.

* * *

The naval radio station at Point Isabel, Texas, is being removed to Fort Brown, Brownsville, Texas, and combined with the army radio station there. Naval personnel will operate the station, using high and medium power tube sets.

* * *

Delicate electrical recording instruments are being shipped from the General Electric Company plant at Schenectady, N. Y., to be used in determining the nature and the strength of the electric current generated by the recently acquired electric eel at the Bronx Zoo, New York City. Preliminary rough tests show that the 5½-foot eel generates 15 volts. This was enough to knock down Keeper John Toomey twice when he was transferring the eel from one tank to another.

* * *

The medal of the Institute of Radio Engineers has been awarded to John Stone Stone for his pioneer work in radio. The presentation took place recently at the Engineers' Club, San Francisco, and was made by Col. J. F. Dillon, supervisor of the sixth radio district, in the presence of a distinguished assemblage. Mr. Stone is now living in San Diego, Cal., where he is engaged in research work as a member of the engineering staff of the American Telephone & Telegraph Company.

Answers to Readers of Radio World

I am submitting a diagram of my six-tube receiver comprising three stages radio-frequency, detector, and two stages of audio, using parts as shown in diagram. Is it correct? Have you any changes to suggest? Do you think it advisable to incorporate a 23-plate condenser in the plate circuit of the detector tube? Will a condenser in the antenna or ground circuit be of any use? If so, what capacity? Will the circuit bring in DX stations?—Howard B. Dale, 103 Decatur Street, Brooklyn, N. Y.

The diagram is correct, except for some minor changes that can very easily be made. Remove the variometer from the grid lead of the first tube. If regeneration is wanted place it in the plate circuit of the detector tube, but with a circuit such as this, it is not advisable to use regeneration. Much better results will be had if it is not used. Also remove the 23-plate condenser from the plate circuit of the detector circuit and grid of the first tube. If neutrodyne reception is wanted with condensers, use separate neutrodons for each tube instead of the method you use. A 23-plate condenser in the antenna or ground lead will cut down on your wave length. It is advisable to use as few condensers (series) in the antenna circuit as necessary and do all the tuning with inductance. Should your set not tune low enough, however, use the condenser in the antenna circuit, and arrange a switch whereby it can be shorted when necessary. A 23-plate condenser will do. The circuit should bring in all the DX stations, weather, of course, permitting and careful tuning being used.

* * *

Does the DeForest set described in RADIO WORLD, *June 23rd, need shielding? If so, where is it grounded when a loop is used? Would an all-wave coupler or any other bank-wound coupler be more efficient than the regular type coupler in this circuit? Would you advise the UV201A tubes in place of the UV201 tubes? Does not the circuit as described need a grid leak?—D. J. Smith, Blackfoot, Idaho.*

If this circuit is carefully constructed and the parts placed with regard to inter-coupling effects, no shielding is necessary. Would not suggest the use of the bank-wound couplers, because of the fact that most radio-frequency transformers are made to work over a comparatively small band of wave lengths and by using an all-wave coupler you would not gain anything, but would not be able to use it at all. Use a coupler with a range of 200-600 meters. You may use the UV201A tubes very well in this circuit. No grid leak is necessary due to the fact that a crystal detector is used.

* * *

Can I use the UV199 tubes in the circuit described on page 9 of RADIO WORLD, *June 23? Can audio-frequency amplification be added to this circuit? In what position should the three coils be mounted on the panel? Should they be stationary or movable?—C. J. Minder, Muscatine, Ia.*

You may use the UV199 in this circuit. A suitable diagram for additional audio-frequency amplification appeared in RADIO WORLD, August 18, in the Answers to Readers department. Use the regular honeycomb coil mounting, which has one stationary coil in the center and two outer ones movable over a 90° arc. You can place the mounting in the most convenient position on the panel.

* * *

Kindly publish a circuit using three UV199 tubes. I have heard that these tubes need special circuits. Is this so? Are they good amplifiers? Can they be used in reflex circuits? Where may I find a good reflex circuit using two tubes and a crystal for rectification?—George Haneburger, Pittsburgh, Pa. Chas. E. Fisler, E.E., Engineering Department, Adirondack Power and Light Corp., Schnectady, N. Y.

You will find a circuit for three tubes in RADIO WORLD for September 1, 1923. The tubes do not need special circuits if directions are carried out and proper resistances are used. They are good amplifiers when used with a C battery, or some means of placing a negative charge on the grid. They can be used in reflex circuits.

For a reflex circuit using two tubes and a crystal refer to RADIO WORLD, March 3, page 4, where you will find the diagram you wish. (Fig. 1, using a loop). Honeycomb coils may be used in place of the loop by substituting antenna and ground for the loop and connecting the two honeycomb coils the same as a coupler, using one as a primary and the other as secondary.

* * *

I have a DeForest D7A receiver and would like to use 1½ volt tubes with the set. Is it possible? How should I do it and what changes will be necessary?—Geo. C. Boyer, Reno, Nevada.

You can use the 1½ volt tubes without changing the set at all. Get the WD12 tubes and plug them in the same as the regular tubes, substituting three dry cells hooked in parallel instead of the storage battery. Or use the WD11 tubes with adapters, using the same three dry cells. No other change will be necessary.

* * *

I intend to use a storage battery with the UV199 tubes. Where can I purchase a 60 ohm rheostat? Will a Bradleystat work? Can I use a 30 ohm rheostat and add one of the 25 ohm resistances to it in series?—Charles Cosman, 22 West Street, Fort Plain, N. Y.

We do not advise you to use a storage battery with these tubes. They are not meant for use with a storage battery and rheostats will only cause you trouble. Substitute the dry cells as specified. Were these tubes designed for use with storage batteries the manufacturers would so state. For a 60 ohm rheostat use the regulation 30 ohm rheostat with additional resistance in the circuit. A Bradleystat will work as the controlling factor as stated above. Yes.

* * *

Will you kindly publish in your Answer to Readers' column a two variometer, variocoupler circuit with amplification? Must be able to bring in the DX stations and have jacks for the amplifiers.—S. Horton, 1314 W. Grant Street, Plainfield, N. J.

Refer to page 12, RADIO WORLD, June 30. Mr. A. E. Herman has written a very excellent article regarding the construction and operation of this type of circuit, giving panel layouts and diagrams that will aid you.

* * *

Kindly advise me where I can obtain blue prints of a set using a loop. I cannot use the outside antenna and ground. Can you also furnish plans for the panel?—E. Lucas, 47 West Market Street, Akron, Ohio.

We do not carry blue prints or panel layouts. Should you need them apply to S. Newman & Co., 74 Dey Street, New York City, who handle matters of this sort and can supply you if you give your specifications.

* * *

How may I increase the wave length of a Coast coupler? Can I use honeycomb coils for the purpose? How should I do it?—R. L. Hilton, 2 Lawrence Street, Waterville, Me.

The wave length of this coupler may be increased by putting a honeycomb coil in series with the antenna and stator and another one in series with the grid and rotor. By so doing, any wave length may be conveniently reached by the use of the proper size coils.

* * *

I would like the most selective sensitive long distance receiver known. It must use two variometers and a variocoupler. Will the addition of a variable condenser and a tapped honeycomb coil make possible higher wave lengths and closer, finer tuning? Will it be of any advantage whatsoever? Will the circuit enable me to receive from coast to coast? How many amplifiers should I use to get best results? Should they be audio-frequency or radio-frequency? Will the Hartman spider web rotor variocoupler give better results than the optional coupler using a ball rotor and tapped bank wound stator? Is there any circuit known which is more selective and which will cover longer distances than this one? Where may I get the circuit diagram of the most selective and sensitive Cockaday four-circuit receiver? Can a coupler be substituted for the two 1,000-turn coils in the Leslie Libby circuit published in May 26 RADIO WORLD, front inside cover? Can any substitution be made for the three 25-turn coils used in the same circuit? What in your opinion is absolutely the best circuit yet discovered for my requirements?—George Allen Gerber, Burlington, Route 6, Wisconsin.

The Armstrong three circuit receiver (two variometer, coupler) is standardized and should be constructed as shown in any of a number of diagrams. A circuit was published in RADIO WORLD, June 30, explaining this circuit using two stages of audio-frequency amplification. It is not advisable to add radio-frequency to a circuit of this type as far as efficiency goes. Do not incorporate any additional condensers or inductances as they rob the circuit of efficiency rather than adding to it. Condensers are not used to tune the circuit and even the condenser in the ground circuit is unnecessary if the coupler is capable of fine tuning with taps. Receiving from coast to coast is a pretty large order, and while 2,000 miles has been covered with the receiver it is doubtful if it is a regular thing. Detector and two stages should prove sufficient for all ordinary purposes. Suggest you use the spider web coupler as it is more efficient as regards distributed capacity. The Armstrong circuit is extremely selective if properly handled, and is the favorite with thousands of fans who know how to operate it. Do not fool around with trick circuits if you wish success. As to a circuit that is better, there are any number that are as good, but we hesitate to prescribe any that are better, as that is almost impossible. Among the principal ones on a par with the circuit are the Hazletine neutrodyne, the Cockaday, the Reinartz, all of which are dependent upon the manner in which the set is constructed and tuned. You cannot use a coupler in place of the coils mentioned in the Leslie Libby article. Do not try to change any of the circuits to please your fancy, but stick to the original diagrams closely. The best circuits for the reception of extremely distant signals are the multi-tube superheterodyne circuits, but they are far too complicated and hard to tune to advise the amateur builder to construct them. Stick to the standard popular circuits and be assured of success. Furthermore, as to the distance any receiver will work satisfactorily over it is impossible to even give a guess. Too many exterior conditions govern the case, and receivers that will not work in one place perform wonders in other places.

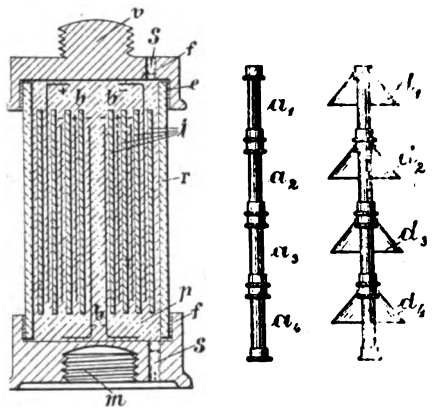
Latest Radio Patents

High Tension Condenser

No. 1,461,287: Patented July 10, 1923. Patentee: Emil Pfiffner, Frybourg, Switzerland.

The high tension condensers used hitherto for the purpose of protection from excess voltage for building up electric oscillation circuits and the like show various defects, which reside in their inadequate electric strength, both with regard to the puncturing of the dielectric between coatings of the condenser and with regard to the discharge at the leading in places.



Construction of condensers allowing flexibility and combining several new features of interest.

The high tension condenser described below avoids these drawbacks by subdividing the fall of potential at the terminals of the condenser into a number of partial falls and thus builds up the condenser from a number of partial condensers connected in series. By this means a far greater degree of safeness is obtained as regards the puncturing of the dielectric, as each partial condenser is capable of sustaining many times the partial fall of potential apportioned to it and even in the case of the puncturing of a partial condenser the remaining partial condensers still have sufficient electric strength to withstand the terminal voltage.

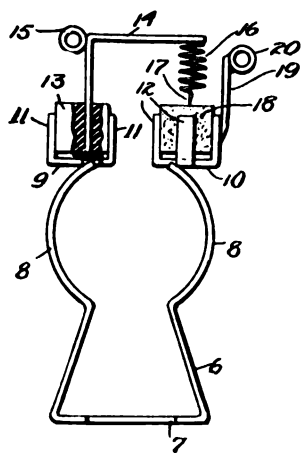
The condenser according to the invention is thus built on the principle of the socalled chain insulators, both as regards the dielectric between the coatings of the condenser and as regards the distribution of potential on the outer surface of the condenser, which is in communication with the atmosphere, while, in contradistinction to the ordinary chain insulators, the distribution of potential is an approximately fully uniform one, for the sake of greater capacity from member to member.

Besides the excellent electrical properties, this construction has the advantage, just as is the case with chain insulators, that condensers may be put together for voltages of any height, by connecting up a number of similar elements in series, each element of which is built for a relatively low voltage, an advantage which is of special importance from the point of view of manufacture.

Wireless Detector

No. 1,460,734: Patented July 3, 1923. Patentee: W. H. Ruf, Roselle Park, N. J.

My invention relates to wireless detectors, my more particular purpose being to give the detector such form that during its active use it may be readily carried around upon the person without causing inconvenience to the individual carrying it, and also to confer upon the detector a high degree of sensitiveness and to give the operator a special and immediate control over its sensitiveness, not generally attained in the use of a wireless detector.



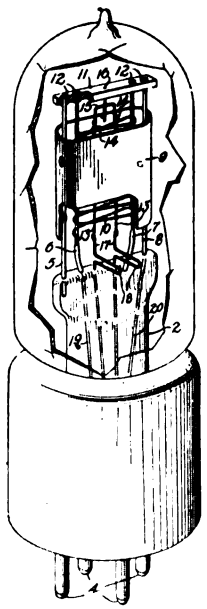
New detector for receiving sets.

Reference is made to the accompanying drawing forming a part of this specification, and in which like reference characters indicate like parts throughout the several figures.

Knoof's Electric Discharge Device

No. 1,456,565: Patented May 29, 1923. Patentees: W. A. Knoof, Brooklyn, N. Y. and P. P. Cioffi, New York, N. Y.

The invention relates to electric discharge devices and a method of manufacturing the same. It has for an object the provision of an electric discharge device in which the need for a glass support for the electrodes in the form of a cane or arbor is eliminated.



Constructional details of Knoof's tube, embodying several new features.

A further object is the provision of such a caneless or arborless electrode mounting as shall provide a rigid and compact electrode unit.

The invention in general comprises a plurality of electrodes which are mounted on a rigid wire frame which is connected to the usual press or squash and are by means of the arrangement of the frame rigidly spaced thereon from each other and the walls of the tube.

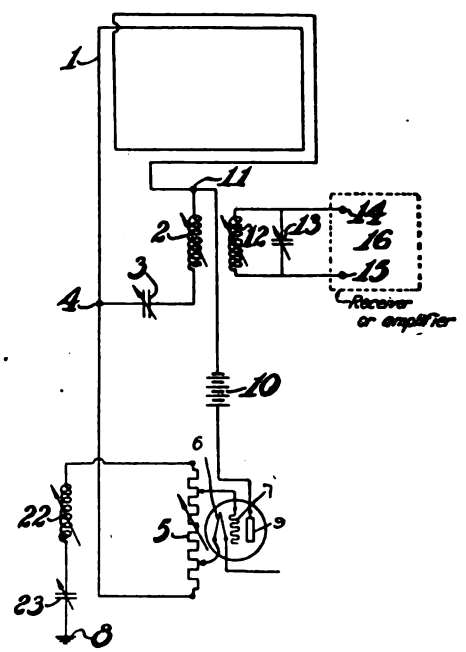
While in the preferred form of our invention, rigid wires are used as frame members, nevertheless a rigid frame providing the same degree of compactness and rigidity may be provided by the use of glass or other members in place of the wire members.

The invention is illustrated in the drawing which represents in a part elevation, part section view, a preferred form of tube embodying our invention.

Directional Radio Receiving System

No. 1,460,861: Patented July 3, 1923. Patentee: R. H. Marriott, Bremerton, Washington.

This application is filed under the provisions of the act of March 3, 1883, and applicant hereby consents that the invention disclosed herein may, if and when patented, be used by the Government or any of its officers or employees in the prosecution of work for the Government, or by any other person in the United States, without the payment to him of any royalty thereon.



System for the reception of unidirectional signals.

My invention relates to radio systems having for its object the unidirectional control of the receipt of signals. To get a unidirectional receiving arrangement, I combine the two-directional characteristics of a periodic loop antenna with the four-direction characteristics of the loop to ground, in the loop circuit via a thermiomic repeater, to neutralize one of the two-directional characteristics of the loop.

This arrangement eliminates the separate open antenna which have been used with periodic loops for unidirectional effects and is less critical for adjustment. Also this arrangement permits of the use of the periodic loop in place of the less efficient aperiodic loop and loop to ground which has been described for unidirectional effects by E. F. W. Alexanderson in Patent No. 1,375,992.

New Applications of the Vacuum Tube

MOST of us are familiar with the ordinary applications of the three-electrode vacuum tube. The function of the tube as an oscillator and modulator, as a detector of high frequency currents and as an amplifier of both radio and audio frequency voltage is too well known by this time to warrant a repetition. Besides these two common uses there are a number of other applications to which the tube can be put, says a writer in the New York Tribune.

It is not a matter of common knowledge that the tube can be used as a voltmeter, measuring both alternating and direct voltages. For the measurement of alternating voltages three properties of the tube are made use of. These are the uni-lateral conductivity, the ability to amplify and the property of its being a voltage operated device. The last named property is very desirable, since it means that the tube requires but a small amount of power in the input circuit for its operation.

The circuit for measuring small a. c. voltages by electrostatic means includes an adjustable grid battery. The output circuit includes a plate battery and a direct current measuring instrument. In operation the plate and grid batteries are adjusted so the tube is being worked at the lower end of the characteristic curve, in which case the plate current will be reduced to exactly zero. If, now, an a. c. voltage is applied to the grid circuit, during a portion of the cycle, the grid potential will become more negative than the potential of the grid battery and during the other half of the cycle will become less negative. In the first case, the plate current will still remain zero, but in the second instance a current impulse will flow in the plate circuit and is measured by the plate meter. In order to return the plate current to zero the grid potential must be increased in the negative direction, and this increase is a measure of the peak value of the alternating voltage on the grid.

In measuring high tension voltages the potential is applied between the filament and plate of the tube. A specially designed tube with a high amplification factor is used. By means of a grid battery potentiometer the grid voltage is adjusted until the current in the plate circuit just falls to zero. Then by a simple mathematical equation the unknown voltage is calculated. To prevent arcing across the internal elements of the tube, the plate and grid are brought out at opposite ends of the tube.

As a power limiting device the vacuum tube finds a wide application. It can be used as a voltage and as a current regulator controlling the output of a generator. The tube in this case is connected in series with the field winding, the grid going to the moving arm of a variable resistance, across the field coils. When the terminal voltage of the machine tends to rise there is an increase of current through the resistance around the field coils. In accordance with Ohm's law, the potential across the resistance rises and in turn the grid becomes more negative and increases the resistance of the tube itself. The increase of the tube resistance cuts down the current through the tube, and hence through the field winding, since it is in series with the tube. When the terminal voltage tends to drop the same process goes on, but the grid in that case becomes positive in value. In controlling the current of a generator the tube is placed in parallel with the field winding.

Another very important use of the tube is in the ionization manometer, an instrument which measures exceedingly low gaseous pressures. It has been found that the gas pressure in a tube is proportional to the number of positive ions formed by the collision of the electrons with the few remaining gas molecules. This is only true, however, if the mean free path of the electrons in the gas is large as compared to the distance between the electrodes of the tube, which occurs at relatively low pressures.

In use the manometer is connected to the vessel containing the unknown pressure, which may be a high power vacuum tube. The grid of the manometer is kept at a positive potential, and the plate at a negative potential, both with respect to the negative end of the filament. The electrons emitted from the filament are attracted to the positively charged grid, some being caught and some slipping through the mesh of the grid and falling toward the plate. Since the plate is negative with respect to filament it is impossible for any of the electrons from the filament to ever reach the plate. They gather an increasing momentum while under the attraction of the grid and attain their greatest velocity in its immediate vicinity. Those that do manage to go through the grid mesh are subjected to two forces, which finally return them to the grid. One of these forces is the repulsion, due to the negative plate, and the other the attraction of the positive grid that the electrons had just passed through, now acting to pull the electrons back to the grid.

Suppose now that gas molecules exist in the surrounding space. Positive ions will be formed by collision if the speed of the electrons is sufficiently great. These positive ions formed between the filament and the grid go to the filament and those that are formed between the filament and plate are attracted by the negative plate and their flow can be measured by an ammeter in the plate circuit, which current flow is a measure of the number of positive ions formed. In the grid circuit is another meter which measures the electron flow to the grid, it being necessary to keep this flow constant.

Such a device indicates rapid changes in pressure because the reading of the plate meter is a direct indication of the amount of gas pressure in the surrounding space. Pressures as low as one billionth of a millimeter of mercury can be easily measured with the vacuum tube manometer.

We have only just begun to realize the vast possibilities of the three-electrode tube, and the above-mentioned uses are but a few striking examples of what the researcher has learned to do with electrons.

WGY Is Heard in Iceland

WGY is the first American radio broadcasting station to be heard in Iceland. In May, Snorri P. B. Arnar, chief radio operator at Reykjavik, 2,600 miles from Schenectady, N. Y., picked up the General Electric Company station regularly, sometimes strong enough to operate a loud speaker. The Schenectady station has been heard at greater distances than Iceland but never before so far north, chiefly because of the limited number of stations in the thinly populated country. WGY has been heard in France, in Chile and in Hawaii. In his letter to the General Electric Company, Mr. Arnar writes:

"Allow me to call your attention to the fact that your wireless broadcasting station WGY, has been heard at this station, being the first American broadcasting station heard here. In May we heard it regularly when atmospheric conditions were favorable, sometimes strong enough to operate the loud speaker. Although other stations were heard, WGY was the strongest and only one I could get the call signal from. I thought this might be of interest to you, as this is the first report from Iceland of a station hearing an American station."

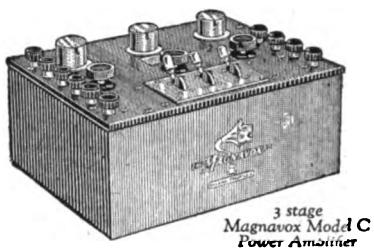
Radio Products



3 stage Magnavox Model C Power Amplifier

The Power Amplifier for your Magnavox Reproducer

The Magnavox Power Amplifier Model C, as illustrated, is a true Power Amplifier, and free from elements of distortion.

Switching from stage to stage is made easy by master switches. Any standard amplifying tube can be used.

Without Magnavox equipment no Radio receiving set is complete.

Magnavox R3 Reproducer and 2 stage Power Amplifier . . . $90.00

R2 Magnavox Reproducer with 18-inch curvex horn: the utmost in amplifying power; requires only .6 of an ampere for the field $60.00

R3 Magnavox Reproducer with 14-inch curvex horn: ideal for homes, offices, etc. . . . $35.00

Model C Magnavox Power Amplifier insures getting the largest possible power input for your Magnavox Reproducer.

AC-2-C, 2-stage, $55.00
AC-3-C, 3-stage, $75.00

Magnavox Radio products can be had of good dealers everywhere. Write for copy of our new booklet.

The Magnavox Co.

$8,710,000,000 Crop Returns Make Farmers Rich Radio Prospects

THE campaign just inaugurated by the National Radio Chamber of Commerce to educate the farmers of the country in the practical every day value of radio, as announced in RADIO WORLD last week, comes at an opportune time.

The cash income of American farmers from sales of this year's crop will be about $200,000,000 greater than last year despite the slump in wheat prices, the Department of Research of the American Farm Bureau Federation has estimated, after a study of production reports and markets.

The increase, according to the report, is accounted for by a probable raise in the value of the cotton crop and of the dairy and poultry output.

Corn, the bureau estimated, will bring more than last year, but hogs may bring less, while it was estimated that cattle and tobacco will yield about the same as last year and wheat will bring considerably less.

The forecast for this crop year is $8,710,000,000.

Putting Radio on the Map of the World

IN its seventh of a series of circular letters addressed to government officials in charge of wireless telegraphy and radio telephony the world over, P. C. Kullman & Co., 110 Nassau Street, New York City, known as the wireless brokerage house, makes these statements:

"Can you, as an official, in charge of and controlling wireless telegraphy and radio telephony in your country, and having at your disposal abundant government funds for the advancement of industry and science, the education of your fellow-citizens, the entertainment and enjoyment of your people, remain inactive and silent in the face of this modern progress?

"Do you know that radio telephony affords employment to a million people in the United States of America?

"Do you appreciate that radio broadcasting is listened to by five million persons in the United States, night after night?"

The circular also carries extensive quotations from RADIO WORLD.

Who Are the Best Distributors?

MANUFACTURERS often ask us this question. F. A. D. Andrea, Inc., is one of the oldest and most successful manufacturers with its plant in New York City, so its judgment may be of value to others in the selection of distributors for Greater New York.

Following are the six well established concerns recently appointed by FADA as its exclusive distributors in the New York metropolitan district:

North American Radio & Supply Company, 5 Columbus Circle, New York City; North Ward Radio Company, 236 Halsey street, Newark, N. J.; Radio Stores Corporation, 218 West 34th street, New York City; Triangle Radio Supply Company, 122 East 23d street, New York City; Victory Electric Company, 1403 Bedford avenue, Brooklyn, N. Y.; National Light & Electric Company, 289 Market street, Newark, N. J.

A New Honeycomb Adapter

A NEWLY patented honeycomb coil adapter, perfected by the F. P. Hall Co., 30 Church Street, New York City, is one of the neatest adapters yet evolved. Due to the fact that a different type of adjustment is provided the range of coupling is practically unlimited as to fineness.

The device itself consists of an angular steel brace fitting against the panel, with the stationary coil at an angle of 45° below horizontal. The movable coil is arranged on a right angled piece well braced, with a screw adjustment which ends in a large knob on the front of the panel. The close coupling is absolute and the loose coupling separates the coils a distance of three inches which is sufficient for all purposes. To illustrate the fine control of the coupling it might be said that it takes 20 complete turns of the knob to separate the coils the full distance.

Aside from the fineness of adjustment the wide range of adaptability is another good point. It is so arranged that the builder may use two honeycomb coils as a variometer or anything his mind might suggest. It can even be used to provide tuned radio-frequency transformers, using two coils as the transformer, and accomplishing tuning by the use of the coupling. It is sturdily made, and needs only two holes to accommodate it to any panel.

Features of WLW's Program

STATION WLW, Crosley Manufacturing Company, Cincinnati, operating on 309 meters, will include in its program for September 17 a number of special Odd Fellows' features in connection with the Odd Fellows' Convention at Cincinnati.

On September 18 a special Atonement program arranged by the Avondale Synagogue will be featured.

TELEPHONE NUMBER CHANGED

The telephone number of RADIO WORLD has been changed to LACKAWANNA 6976

Radio Literature Wanted

Manufacturers of and dealers in radio apparatus and accessories are notified that literature and catalogues describing their products have been requested, through the Service Editor of RADIO WORLD, by the following:

E. G. Voell, 435 Cattell St., Easton, Pa.
R. E. Bowman, 1215 West Eighth St., Wilmington, Del. (Interested in parts and a simple DX set.)
L. E. Eaton, Duncan, Okla.
Rafael Gabaldon, Bocono, Venezuela. (Wants correspondence with manufacturers with view to becoming distributor and retailer.)
Emeral White, Exton Ave., White Horse, Trenton, N. J.
F. Willard Halstead, 167 Park St., Waterloo, Iowa. (Manufacturer and retailer.)
N. W. Andrews, 518 Colo Ave., Walesburg, Colo.
Maurice & Co., Langton News, Delacourt Road, Blackheath, S. E. 3, England.
Nevada Electrical Engineering Co., F. W. Humrich, manager, Nevada, Iowa. (Retailer.)
William Bodley, 4915 Forsyth Ave., East Chicago, Indiana. (Interested in transmitting apparatus.)
George A. Muir, 292 Madison St., Memphis, Tenn. (Will open retail radio store shortly.)
Julius Joseph, Jr., 1114 Seaview Ave., Far Rockaway, N. Y.
Henry Du Bois, 171 Westminster Place, Lodi, N. J.
Geo. W. Blatchley, Jr., R. D. 6, Freehold, N. J. (Will build some new apparatus soon.)
R. G. Phillips, 63 East 36th Place, Chicago, Ill.
Vernon Jaynes, Box 25, Parkersburg, Iowa.
Albert Poivier, 1 Athletic Ave., Cote des Neiges, Montreal, Canada.
Leslie J. Voorhees, 27 Charles Street, Pittsfield, Mass.
Jerome Karmiol, 1526 39th street, Brooklyn, N. Y.
E. C. King, 836 N. Robberson Ave., Springfield, Missouri. (Will buy factory made set.)
Don Smith, Box 107, R. F. D. No. 2, Augusta, Kansas.
Arthur Beach, Beacon Falls, Conn.
John S. Welch, 316 East Twelfth St., New Albany, Ind.
W. N. Anderson, 2824 Euclid Ave., Kansas City, Mo. (Interested in home-made tube set.)
Mott Souders, Jr., 206 North Broadway, Red Lodge, Montana.

Station WOR Backs Down in the Music Fight

STATION WOR, operated by L. Bamberger & Co., Newark, N. J., has abandoned its appeal to the Supreme Court in the music copyright fight and has applied for and been granted a license to broadcast copyrighted music controlled by the American Society of Composers, Authors and Publishers, according to a circular issued by the latter.

The circular gloatingly concludes: "More than ample radio 'plugging' opportunities are now available to our members."

New Radio and Electrical Firms

The Audio Laboratories, New York City, has increased its capital stock from $5,000 to $20,000.

Kelly Electric Co., 523 Elm Street, Cincinnati, has been incorporated with a capital stock of $10,000.

S. Davis Electrical Co., New York City, $10,000; N. H. Streimer, B. B. Kalman, M. L. Margoshes. (Attorney, H. Margoshes, 302 Broadway.)

Milwaukee Radio Amateurs' Club Resumes Meeting

THE first meeting of the Milwaukee Radio Amateurs' Club, Inc., following the annual summer recess will be held on September 20, at 8:00 p. m., in the Trustees' Room of the Milwaukee Public Museum. One week later the society, which is over six and a half years old and is now a non-stock corporation, will hold its annual corporate meeting at which there will be an election of members of the board of directors. The newly selected directors will then appoint the five general officers and the committee chairmen.

At the several mid-summer meetings of the present directors extensive plans were formulated for a fall membership campaign. Not only radio amateurs living in the city of Milwaukee will be invited to join the club, but all those residing in the city's suburbs and surrounding county. The society has long been affiliated with the American Radio League and in reality is a local section of it; therefore all of the A. R. R. L.'s local members will be solicited as well as licensed radio amateurs. The club is primarily one for amateurs, but membership is open to others interested in radio, particularly to technically inclined broadcast listeners.

A lecture program is being arranged. The committee in charge promises to present during the season some of the best known amateurs in the country as well as several high league officials and men in the commercial side of the radio field who have a known reputation as designers and manufacturers. Traffic discussions and means to reduce any local interference that there may be will receive the attention of some gatherings of the members.

General co-operation with all other interests in the radio field will constitute the policy of the Milwaukee club. No great financial obligations are assumed by joining, and with 100 per cent. of the amateurs represented the association can act as one for all amateurs in any question involving their rights. The club's mail address is 601 Enterprise Bldg., Milwaukee, Wis.

Radio Dealers in Mexico

THE Radio Trade Association, 1133 Broadway, New York City, has supplied to its manufacturer members a list of electrical dealers in Mexico with street addresses and other pertinent information. The importation of American radio apparatus into Mexico is duty free.

Radio Show Will Start Season With a Boom

THE second annual American Radio Exposition, which will be held at the Grand Central Palace, New York City, from October 6 to 13, is expected to inaugurate the biggest and best season yet enjoyed by the radio industry.

Over 60 exhibitors already have contracted for more than 100 booths and it is certain that when the doors are opened to the public every inch of exhibition space will be occupied.

A number of new features will be shown, all of special interest to people who are not now owners of receiving sets.

J. C. Johnson is general manager of the exposition. He may be addressed at the Grand Central Palace, New York City, for particulars regarding this important event.

Radio Protection for Nantucket Shoals

A NEW lightship, equipped with a radio fog signal, has been put into service on Nantucket Shoals, Secretary of Commerce Hoover announced recently.

The new vessel will have the first radio fog signal, an automatic apparatus sending during fog a group of four dashes every 30 seconds, enabling vessels with radio direction finders or compasses to obtain an accurate bearing from a distance of 30 miles or more in any weather, and to steer for and "make" the lightship. The light vessel will also have two other fog signals, a powerful steam whistle, and a submarine bell; a little later a submarine oscillator will be substituted for the bell. The electric signal light of 3,000 candle-power will show at the masthead. There is radio equipment for communication, with a radio operator in attendance, reporting vessels in distress, as well as for the maintenance of the light vessel itself.

Broadcasting in Sweden

THE status of broadcasting in Sweden is a curious one. The Government has now decided that transmitting stations will be constructed by the state, but will be leased to operating companies. Receiving stations may be established by private persons upon obtaining a license from the Government, Commercial Attache H. Sorensen at Copenhagen reports.

Radio Trade Notes

Maurice & Co., radio engineers, Langton Mews, Delacourt Road, Blackheath, S. E. 3, England, inform Radio World that they are desirous of importing American radio goods. Address Mr. E. N. Gill.

* * *

George A. Muir, 292 Madison street, Memphis, Tenn., will shortly open a retail radio store. He wants information on radio parts, cabinets and panels.

* * *

E. C. King, 836 North Robberson avenue, Springfield, Mo., writes to RADIO WORLD that he will be in the market in ninety days for a factory-made receiving set. He also is interested in sets having detector only and with one and two steps of audio-amplification.

* * *

L. H. Hardy & Sons, Inc., have opened a retail radio store at 528 Sixth Avenue, New York City.

Sunday Program from Station WGI

ON Sunday, September 16, Station WGI, Medford Hillside, Mass., will broadcast the following program:

4:00 P. M.—Twilight Program.

1. "Adventure Hour," conducted by the Youth's Companion.
2. Stories by Arturo.
3. Concert Program by the Edison Laboratory Phonograph, courtesy of Vocalion Hall.

8:30 P. M.—Evening Program.

1. Twelfth of a series of talks on "World Unity," conducted by the Federation of Churches.
2. Musical concert arranged by Miss Alice McLaughlin, soprano.
3. Musical concert arranged by Frederick K. Hall, violinist and pianist.

Coming Events

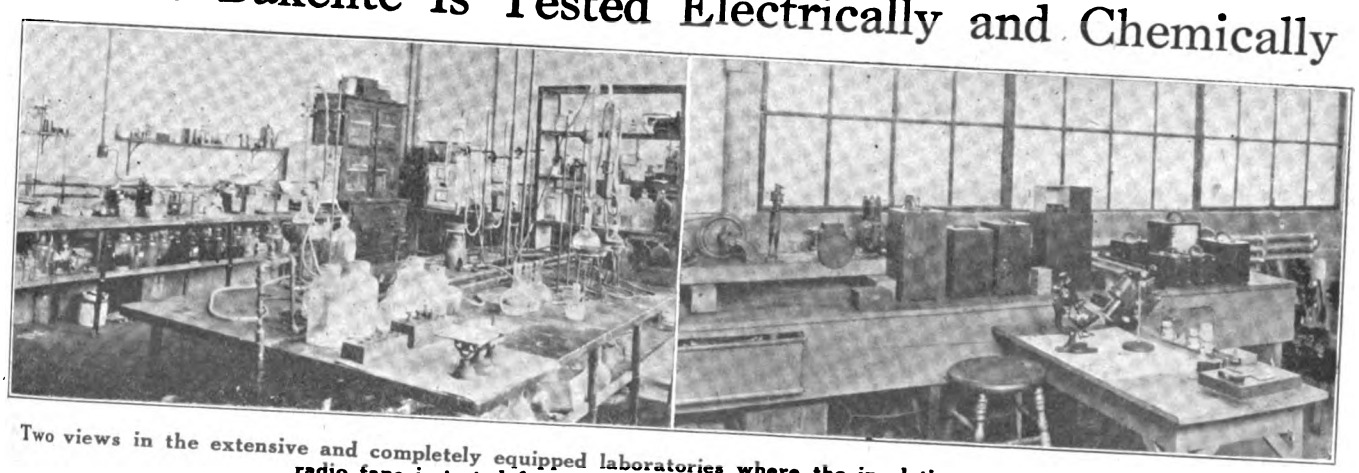
NATIONAL RADIO WEEK, November 25 to December 1, 1923.

AMERICAN RADIO EXPOSITION, Grand Central Palace, New York City, October 6 to 13, 1923. J. C. Johnson, general manager.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS, Pacific Coast convention, Del Monte, Cal., Oct. 2-5. F. L. Hutchinson, 33 West 39th Street, New York.

AMERICAN RADIO RELAY LEAGUE, second national convention, Chicago, Ill., September 12-15, 1923. Chicago Radio Traffic Association, 959 The Rookery, Chicago, Ill.

Where Bakelite Is Tested Electrically and Chemically



Two views in the extensive and completely equipped laboratories where the insulating material "bakelite," familiar to all radio fans is tested for mechanical strength and insulating qualities.

IMPORTANT NOTICE

While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

WGY Is Easy to Get

AN interesting record of radio reception was recently reported by M. .S. Shapleigh, a Waynesboro, Pa., radio fan who has been in the air nightly since February 20, 1923. His log shows that up to July 31 he listened in 151 nights and during that time picked up WGY, for the whole or part of the program, 82 nights. Inasmuch as WGY was not in the air forty nights during the period observed, the Waynesboro man missed the General Electric Company station only 29 nights. In his report, Mr. Shapleigh writes: "WGY tunes in easier and with less interferences than any of the 65 stations we have listened to since we got our set." Waynesboro is approximately 260 miles from Schenectady, N. Y., the home of WGY.

He Used Radio Bait

A FISHERMAN who was having wonderful success while his friends were coming home with only empty creels and appetites was asked by one of them to what he attributed his exceptional luck.

"Luck?" he snorted, "that isn't luck! I just cater to the fish."

"Cater to the fish? What do you mean?" queried the mystified friend.

"Well, I take my radio set along and drop the ground wire down along side of my hook. Then I tune in station WORM," he said—and started to run.

Strong Praise—Thanks!

EDITOR, RADIO WORLD:

I buy RADIO WORLD regularly because it has more real meat for the "radio bug" than any other publication—and I read them *all.*

Yours truly

PAUL THORNE.

More Prizes for Radio Drama

THE announcement by WGY, the General Electric Company radio broadcasting station, of a prize offer of $500 for the best radio drama submitted during the three months period ending November 30, has brought hundreds of letters of inquiry and there is every evidence that many contributions will be made.

Additional prizes in varying sums up to $100 will be awarded for other plays deemed suitable for radio production. The offer of the General Electric Company is made for the purpose of stimulating interest in the writing and development of a new form of drama, a play which reaches its fullest appreciation through the ear, the mind and the imagination.

Plays will be considered that fall under any of the following classes: Drama, melodrama, comedy-drama, comedy and farce-comedy. Manuscripts must be original and must be accompanied by written permission of author (or, if copyrighted, by the person or persons controlling the copyright) giving the General Electric Company exclusive right to produce the play by radio. Rights for use other than radio may be reserved by the author. Two copies of each play must be forwarded and should be sent by registered mail. The author should retain a complete copy.

The author's name must not appear on any manuscript offered in competition. Instead, the manuscript should be signed with a *nom de plume*, which must also be written on a sealed envelope containing the contestant's real name, address and permission granting exclusive right to produce the play by radio. This envelope should be enclosed with the manuscript and will not be opened until the award has been made. A synopsis of the play must be attached to each manuscript.

A play requiring one and a half hours for performance is desirable; in any case the time should not exceed two hours. Small cast plays, employing five or six characters are best adapted to radio, as they permit quick comprehension of the plot and give rise to no confusion in distinguishing characters. Plots must be clean with no attempt at questionable situations.

Jewish Religious Services to Be Broadcast

RADIO as a vehicle for overcoming religious misunderstanding is to be utilized by the United Synagogue of America, according to an announcement issued last week by Rabbi Samuel M. Cohen, executive director of that organization, which comprises the 175 leading conservative Jewish congregations of the United States. Arrangements for broadcasting complete programs of religious services preceding all the Jewish festivals have been made by Rabbi Cohen with the American Telephone & Telegraph Company. The programs will be sent out from WEAF and WMAF.

San Francisco-Cavite by Radio Twice Daily

THE United States Navy Radio station at San Francisco now receives messages direct from the station at Cavite in Manila Bay twice daily as a result of improvements just completed.

The two schedules of filing are at 2 A. M. and 2 P. M. Previous to the recent improvements the only filing schedule was at 2 A. M.

The distance by great circles from Cavite to San Francisco is 6,221 miles, and so far as known is the longest one way radio circuit in the world actually handling traffic.

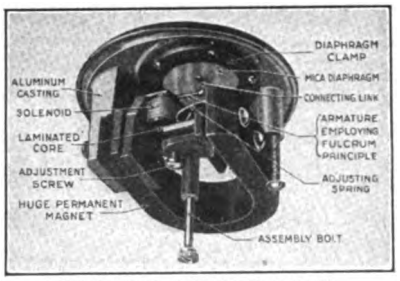
TYPE "A1"
21" FIBER
HORN
$25.00

TYPE "B"
(For Phonographs)
$12.50



INTERIOR CONSTRUCTION

An ear phone is an ear phone no matter how fancy the horn that covers it may be, and, due to the delicate construction of an ear phone it is utterly incapable of giving true tone reproduction, especially, when relatively large currents are passed thru its coils, such as the output of a two-stage or power amplifier.

The Trinity Loud Speaker element embodies the well-proven and tested principles of the phonograph reproducer with the soundest principles of electromagnetic design best adapted for loud speaker operation. It is not an ear phone when placed on a head band and a loud speaker when covered with a horn. It is a sturdy loud-speaking element ALWAYS.

The Wireless Oracle

By Hirsch M. Kaplan

Say, did you hear the Zimbler Trio? You didn't, and they were on the air twice? Well, you must be asleep!

WFI gave us an afternoon program by the Bellevue-Stratford Orchestra. They're the berries.

I think in the near future we'll conduct a contest for the most popular orchestra that plays or has played over the radio. What do you say?

For you fans who would like to continue dancing after the Lucky Strike Orchestra has done their bit, I suggest tuning in Meyer Hoffbrau's Orchestra at Station WGY.

Lillyan May Challenger is still making herself a favorite with the radio audience.

WHAZ makes me think that they are a local station by the way that they come through. They had some good vocal selections to offer.

WDT, you made an attempt at improving your station, but aren't you going through with your plans?

Again we see that this column must do some good, for again we've had the celebrated violinist Illumento Miserando over the air. Fine stuff, Illumento.

WNAC helped us to pass a pleasant half hour by offering the Cherub Trio.

"Jolly Bill Steinke," the popular artist, was with us once more. He had his dog with him or I'll say that he gave a fine imitation of one. Excuse me for giving your secrets away, Bill.

Just let me give you readers who have no radio sets at present a bit of advice. The programs are getting better and better each day. There is no doubt that when the cold weather arrives and we don't wish to leave the house, the programs then offered will make us forget that the cold weather has arrived. So, you'd better get your set now and not miss anything.

Station KLK, the Oakland "Tribune's" station at Oakland, Cal., is now sporting a slogan. If you should hear "Where Rail and Water Meet" some evening or morning, you'll know where it comes from. Little danger now, though.

Where do all these swell orchestras come from? This time it's the Blue Ribbon Syncopators. They're some jazz babies.

Yes, Roxy and his clique were on the air again and they were better than ever.

Well, I suppose you danced to the music of the Hotel Astor String Ensemble and Orchestra, What! You didn't? What's the matter—got two left feet?

The Four Aces Male Quartet from WMAF had a splendid program.

Would appreciate hearing from you folks as to how you like this column. Any suggestions or criticisms would be

Heard at the Radio Counter

Part XXII

SAY, Brown, have you noticed that there was not such a slack summer this year as last?"

"Have I? Now you're talking foolish. Didn't I lose a week of my vacation just because of it?"

"Well, you should worry, look at the extra commissions that you will get—maybe."

"Well, that's O. K., but you know that I think that the reason for the whole thing is that last year the amateurs were sceptical about summer receiving, simply because they had heard of the bug-bear of static, and this summer they realized that it was not such a terrible thing because of the explaining done in various magazine articles."

"Guess you're right there, old man. Wonder what this fellow wants? He has been looking in the window for the past half hour and finally seems to have picked up enough courage to come in. Guess I will take him, and then go out to lunch. Wait for me, will you?"

"I beg your pardon, but I wonder if I might ask you for some information regarding an inexpensive receiving do-dad for my nephew?"

"Surely, about how much did you want to expend in the purchase of a set? We have them at all prices."

"Well, I understand that those that have lamps are pretty expensive, but I am willing to spend $50.00 if that will get a complete machine."

"Well, we can sell you this one over here for $48.50 complete this week, from antenna to ground. It is a special sale, and a very fine instrument made by a Western concern. Would you care to see it demonstrated? Kindly step over into this booth, and I will connect it for you."

"Why, that is fine, it seems so loud and clear. What station is that talking now?"

"That is WOR, Newark, New Jersey, giving baseball scores."

"Really, do they give out the scores by, er, radio?"

"Surely, and that is not all. The latest sport news as well. I take it you are interested in baseball?"

"Well, I never did care for nothin' in the way of sports except the game. Wonder if I could take that now? Do you have them done up, or do you have to send them?"

"We have them all packed in export cartons. Be careful to follow the diagram in connecting the batteries and unpacking the tube—do not call it a lamp."

"Well, here is your money. I want to thank you, and I will drop in if I have any trouble."

"Perfect. Good day, sir."

WOC Resumes Full Schedule

STATION WOC at Davenport, Iowa, announces that it will resume its full winter schedule on Sunday, September 16. This schedule comprises a musical program every night in the week, except Tuesday, and a more extensive program on Sunday evening than heretofore. Details of the new programs will be released through the various publications and will be announced by radio, so that all may acquaint themselves with the changes being made.

Back numbers of Radio World supplied at regular price of 15c. a copy. Any 7 copies for $1.00. Radio World, 1493 Broadway, New York.

Tune in the world with a CROSLEY Model XJ

Sebring, Fla., heard Honolulu. A man writing from Nassau, British West Indies, says, "First of all on Friday night last June 29, 1923, I heard Honolulu." These records were made with a Crosley Model X. Thousands of letters have come to us unsolicited, telling of the wonderful performance of this instrument.

The new Model X-J, combining all the features of the Model X, with greater refinement of detail, is even better. It is a 4-tube set incorporating one stage of tuned radio frequency amplification, detector and two stages of audio frequency amplification with jack to plug in on three tubes for head phones, new Crosley multistat, universal rheostats for all makes of tubes, new condenser with molded plates, filament switch and other added features.

We believe the Crosley Model X-J to be the most efficient radio receiver ever offered to the public regardless of price. Write to-day for free catalog describing the Model X-J and other Crosley receivers and parts.

Propose a Broadcasting Monopoly for Sweden

A NOVEL plan for organizing radiophone broadcasting in Sweden, designed partly after studying experiences in other countries, especially the United States, and following the lines previously drawn up by the Swedish Government Department of Telegraphs, has been submitted to the Government by a corporation now being formed. This company seeks a joint monopoly with the Government on radiophone broadcasting in Sweden. Among the founders of the new corporation are the L. M. Ericsson Telephone Company and leading manufacturers of electrical and radio apparatus.

The plan provides for extensive co-operation with the Government, which is to erect the sending stations successively. These stations will be at the disposal of the new operating company at least five hours a day for an annual fee corresponding to 6 per cent. of the cost of construction of each station. In addition the company must pay for the power as well as for the bulbs used.

It is suggested that individual owners of receiving sets be required to pay an annual license fee of 20 kroner, or about $5.40, and that societies, places of entertainment, etc., pay a maximum fee of $1,000 kroner. Any make of receiving set may be used. The operating company agrees to provide in its constitution that the annual dividend shall not exceed 7½ per cent. cumulative. The period of the company's concession is for ten years ending in 1934, after which the Government is to have first option on taking over the complete monopoly upon the payment for the equipment.

One of the clauses in the proposal provides that whenever the state has some urgent report to broadcast during the company's allotted period of five hours, such report shall be sent broadcast without a charge to the state. The radio entertainment program includes general news, economic reports, weather reports, lectures, etc. On Sundays religious programs will be given. It is planned also to have special programs for children during the week.

Regarding the broadcasting of advertising matter the new company endorses the government's recommendation that this be limited. It proposes that such material be of the type usually run in newspapers as reading notices. The danger of unfair competition with newspapers in the distribution of news will be avoided through an arrangement with the Central Co-operative News Agency of the Swedish Press, which will select and edit all the news.

$7,000,000 for Ford Advertising Next Year

YOU'D think that if there was one thing in the world that didn't need advertising, it would be the Ford car. Henry Ford doesn't think so, however. In spite of all the free publicity the car gets, in spite of the fact that at present the production is behind the demand, Mr. Ford has announced that his company will spend $7,000,000 in newspaper and magazine advertising in 1924. Any business man in the radio field can afford to follow Henry Ford's ideas—he's proved their worth.

Italy May Get Radio Station from Germany

Writing from Rome, Italy, Commander A. Tosi informs the New York Tribune that a question which is interesting to radio as well as governmental circles just now is: "Should the Italian government accept as part of the reparations a complete radio station which it is believed the German government is willing to send to Italy?"

From my own point of view I think that in the light of the new discoveries which Senator Marconi has just made (and complete details are known to only a few) it would be a great mistake. By accepting this complete installation Italy may be getting something which in a few months will be absolutely obsolete. When it is clearly seen how Marconi's new discoveries affect the present wireless system, then only should such a decisive step be taken.

With the settlement regarding cable concessions Italy has had a setback which will delay her reaching a state of perfection in her radio service which she had hoped to attain by now.

The Italo-South America cable will link up two continents. The Italian station will be at Fiumicino, seventeen miles from Rome. The line will pass from Italy to Malaga, the Azores, then to Rio de Janeiro before reaching the other terminus, which is Buenos Ayres. The length of the cable will be nearly 7,300 sea miles. The other cable (which will link up Italy and North America) is called the Italo-Azores and consists of a new cable from Italy to the Azores joining there to the old German cable, which was given to Italy as war reparations by Germany.

Though the thought of linking up Italy and North and South America by cable has been pleasing Italians in both continents, in reality Italy has been for the past five months connected by radio, as the new Coltano station near Pisa is in constant communication with the South American radio stations.

Few except radio experts realize that Italy has a wireless station under control of the navy which is second to none, in installation and service, in the world. The Italo-Azores Company will lay the cable at its own expense without any material help from the Italian government. As the cost of installing wireless is less than that of laying a cable it is possible that the Coltano station could cut the price of transmission so that the cable company could not make expenses, or on the other hand the cable company might cut rates to such an extent that Coltano would be the sufferer.

It is well to remember that though this company has no subsidy or guaranty, its officials must have some verbal assurance that there will be sufficient business to keep the cable from dying as soon as it is born. It would be foolhardy for any company to erect a station and lay a cable without exactly knowing how business is going to run.

Evidently the Italian government has assured this company that the Coltano station will not cut prices to their disadvantage. If so this arrangement will certainly paralyze Coltano when the cable is in good working order.

In the light of the new Marconi experiments the expense of laying cables seems preposterous when one thinks of Senator Marconi's predictions after his recent experiments. He promises that once the radio stations between North and South America have been erected a message by wireless can be sent at a cost of about seventy centimes to North America and one lira and a half to South America, thus representing about one-tenth of the amount at which the cable tariffs have been fixed.

When motor cars were first invented opposition was raised to them, and the same is true with every new invention. Progress cannot be kept back. Even the most pessimistically inclined against radio must realize that the day will come when Italy, too, must have her perfect system.

Radio World is $6.00 (52 issues), $3.00 six months, $1.50 three months, 15c. single copy. Radio World, 1493 Broadway, New York City.

COME IN AND GET BIG VALUE!

FOUR REASONS FOR ADVERTISING IN RADIO WORLD'S FALL BUYERS' NUMBER

1 At four dollars an inch (yearly contract rate) 74,000 radio-buying readers learn of your goods—a greater number of eyes than four dollars can reach in any other radio advertising medium.

2 Radio World gives **quicker results**—i. e., advertising copy received by Thursday p. m. is published and on the news-stands the following Wednesday morning.

3 A Weekly has greater **reader interest**—the Saturday Evening Post, Literary Digest, Iron Age, are Weeklies. Radio World, the big success of radio, is published every week.

4 Advertising is a gamble. Life itself is. A gambler bets his money on past performances. Radio Corporation of America tried out **Radio World,** then gave us a yearly contract. Magnavox tried us for small space thirteen times, and have just renewed for fifty-two times, using pages. The Federal Telephone & Telegraph Company investigated us from every angle for weeks, then gave us a fifty-two consecutive issue order. A four-time trial of Radio World almost invariably ends with a fifty-two time contract at $120 per page net or $4.00 an inch.

DATE OF THIS IMPORTANT ISSUE—OCTOBER 6

(LAST BLACK FORM CLOSES SEPTEMBER 27)

Special service and value to advertisers in Radio World's **FALL BUYERS' NUMBER:** All advertisers who give us copy for quarter page or more space in Radio World's **FALL BUYERS' NUMBER** will, on request, have their announcements appear in **two colors at the price of one**—in case copy is in our hands by September 24.

Write, wire or phone now for special positions

Another Use For Loud Speaker

When the static is too great for radio reception your AUDIOPHONE Loud Speaker can be used with the Bristol Phonograph Record Reproducer on your phonograph. Then you may have concert or dance program without interruption.

Attached instantly without mutilating the instrument in any way—the Bristol Phonograph Record Reproducer can be used with any make of phonograph. Equipped with such an outfit there are no disappointments—it is always ready—never fails. For dance music you have the equivalent of an orchestra, but without the expense.

The tone of the phonograph thus amplified thru the AUDIOPHONE has volume enough to fill large rooms and the quality is round—smooth—and beautiful—entirely free from mechanical noises.

Remember that the same AUDIOPHONE Loud Speaker is used in common for both radio reception and phonograph record reproduction.

A LOUD SPEAKER and REPRODUCER IN ONE

BRISTOL AUDIOPHONE

MORE THAN A LOUD SPEAKER the AUDIOPHONE is a real reproducer of the original broadcasting. It is easy to listen to the Audiophone reproductions because they are so perfect. The speech, songs and instrumental music are not blurred or disguised by mechanical distortion. You get all the fine shadings and every inflection. In fact, the very personality of the artist seems to be present as you listen.

DEVELOPED in the laboratories of an engineering firm known the world over for recording instruments of precision.

COMPLETE in every way and ready to connect to the receiving set.

NO AUXILIARY BATTERIES are required for magnetizing.

ADAPTED for use on all types of two or three stage power amplifiers.

MADE IN TWO MODELS:

BRISTOL AUDIOPHONE SR. Loud Speaker, Size of Horn 15-inches Diameter, Price..... **$32.50**

BRISTOL AUDIOPHONE JR. Loud Speaker, Size of Horn 11-inches Diameter, Price..... **$22.50**

THE BRISTOL SINGLE STAGE POWER AMPLIFIER can be furnished for use with the usual two-stage amplifier and will greatly increase the range of the Audiophone Price..... **$25.00**

THESE ROMANY PEOPLE APPRECIATE RADIO BROADCASTING

(C. Gilliams Service)

Although they still retain the customs of their ancestors, these modern gypsies have proved that they are up-to-date as far as the comforts of modern conveniences can make them. They use an ultra-modern radio receiver that works on a loop, with dry cell battery tubes. After the long day's trek over country roads, these roaming nomads gather around the set, much the same as they used to gather around the musically inclined members of their tribe, and listen to the news of the day and some good dance and vocal numbers. The particular group of gypsies pictured here were caught listening in on the baseball scores while camped near Newark, New Jersey.

Randel Wireless Company
5 Central Ave. Newark, N. J.

The Wireless Oracle

By Hirsch M. Kaplan

Say did you hear what the regular announcer of station WHN had to say the other night? If you didn't, here goes for an earful. "The mechanical equipment of our station is being improved daily." Yes, we've already noticed that. "And, within a very short time our station will be equipped with the best equipment possible. We are aiming to make station WHN the most powerful station in the country besides offering the best programs obtainable."

You sure are there with plenty of volume WBAK. Do you ever broadcast a regular program?

While listenin' in for DX have you ever missed the call letter of a station only to hear them say "Tulip Town"? Well, just to enlighten you, that was station KDZR of Bellingham, Wash.

The people of Newark, N. J., ought to be proud of having a station like WAAM. Compared to the size of the town and the population of this burg this station is keeping pace with most of our larger stations. The popular program as offered by Mr. Hanbury the other night was great stuff!

Somehow or other we can't get excited over "lyric sopranos" on the air. The girls try hard, and they must be good or they wouldn't get the chance to do their stuff, but it certainly doesn't come in so wonderful.

The Oriole Orchestra, from Chicago, came through kinda mushed up, but the announcer from WJAZ could be heard distinctly with the phones held ten inches from the ears. Walter Graham, my second "op," thinks that they were the bees' knees.

WMAF again helped us to spend an enjoyable evening by offering the West End Ladies Trio. Programs of their sort are never tiring.

Although Nat Sanders and his popular program was the berries, his impersonation of Jimmy Sheares' song, "Hot Roasted Peanuts" was poor.

By the way have you noticed how popular Jimmy Sheares' hit has become? Only the other night I heard three orchestras, two pianos, five popular singers and one violinist play that number.

We have it fresh from the post office that our "Friend Henry" has decided to erect a broadcasting station at Dearborn, Mich., that will reach to every corner of the country. Preparing for the 1924 campaign, Hank?

The Hotel Adelphi's Roof Garden Orchestra through WOO would make a wooden image do a "can-can."

WBS, can't you get in stride with the steps of progress that radio has been and is taking? Your modulation and phonographic programs are still rank.

We can well believe that story about static starting in Mexico. Every time we swing our loop in the direction of WIP we pick up more than our share of those joy-killing sounds.

There seems to be great competition among the dance orchestras of our various ocean liners. First we had Paul Whitmen's S. S. "Leviathan" orchestra, then the dance orchestra of the S. S. "Berengeria," and the other evening we had the orchestra of the S. S. "Paris." They all provide such sterling entertainment that it would be very difficult to proclaim one better than the other.

WAAM, although a small powered station and on a low wave, still make themselves conspicuous by their popular programs, through a station that ranks with the best. That's the stuff. You sure do set a fine example for your complaining brothers.

An Anti-Interference Circuit

By C. White, Consulting Engineer

AMATEURS who are complaining as to the non-selectivity of the circuits they are now using, are advised to pause and take a good look at the circuit herewith described. We have all heard of the four-circuit receivers and all the others that make such marvelous claims for selectivity. Here is a double circuit with the addition of a double wave-trap circuit, that virtually makes it a four-circuit selector. If this circuit does not eliminate interference in nearby or interfering stations, the case is helpless. With this circuit one should be enabled to tune out two stations above and below the desired station, and hear the desired station whether it is DX or local. The circuit has been tested and works to perfection as a selective circuit.—Editor, RADIO WORLD.

WE are constantly searching for the ideal circuit but with every circuit there is some drawback that makes it non-acceptable under certain circumstances. To me it seems that the problem nowadays is to get greater selectivity and more quiet operation under all conditions.

There are many excellent ways that we can accomplish this, but in so doing we must be guided by the financial side. A multi-tube set has the disadvantage of rather high maintenance cost, such as tube renewals, batteries, etc. Then, on the other hand, a single tube must needs be limited for many reasons from performing well under all conditions.

The great question sums itself up as to how we can get sensitivity and selectivity with a single tube and no radio-frequency amplification. I do not intend completely to answer that question. If I could I would be more than glad to write it up, but I will say that we can go a long distance toward the ideal by improving your circuit from time to time in the many ways that are constantly being suggested in RADIO WORLD. It will pay you to keep close track of these.

The circuit I am going to outline is a combination of the Reinartz idea of regeneration, tickler regeneration and a multiple filtering method. An anti-capacity switching arrangement allows you to choose either type of regeneration that is best adapted to your needs and the two filtering circuits allow you effectively to cut out any two stations that are causing considerable trouble. It has been my general experience that interference is often two-fold and a filter that is capable of only cutting out one station and not the other interfering station only half does the trick.

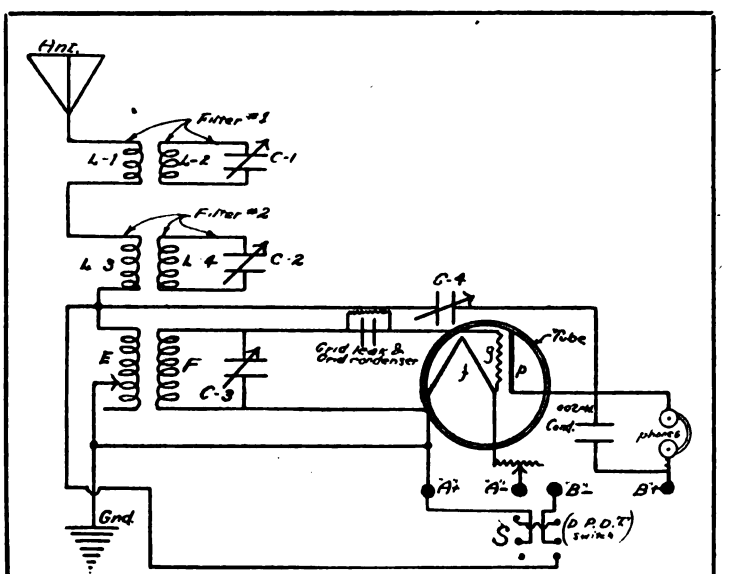

Diagram of a circuit that is ultra-selective. The selectiveness lies in the four inter-coupled selector coils as shown by L1-L2, C1; L3-L4, C2, and the addition of the condenser C4. If constructed according to the directions and carefully made, absolute selectivity is possible.

After looking at the diagram I guess you will think there are too many expensive condensers in the circuit, but if you already have some condensers on hand you will only have to purchase a few new ones, since the condensers in a few places in the circuit are very flexible as to size. And besides it is well worth the extra trouble and expense to get a set that is remarkably free of interference and noise.

In constructing the receiver you must adhere fairly close to the assembly details in order to get full advantage of the circuit efficiency. It is quite obvious that a cabinet larger than the customary size must be used for this tuner. Do not try to crowd the wiring detail in the ordinary single tube cabinet. For example, the filtering circuits, L-1, L-2, C-1, L-3, L-4 and C-2, must be assembled separately in a shielded compartment in order to prevent inductive coupling between the L-1, L-2 and the L-3, L-4 group of coils. A shielded partition can easily be made of copper foil mounted on a thin wooden partition. Then, again, there should be a similar partition between the filter L-3, L-4 and the main tuning coil E-F to prevent inductive coupling. The panel of the set should be covered with copper foil on the inner side, and all the grounding pieces of copper foil should be electrically connected together and attached to the ground terminal of the set. It is advisable to have all wire insulated with spaghetti, especially where the con-

Stopping Autos and Airplanes by Radio Officially Denied

WASHINGTON, D. C.—Public antipathy against Germany's war plans of the future should not be increased by the report from Berlin that the German Government can stop and render powerless automobiles, airplanes or other motor vehicles by radio. Herr Prostrat Hermann Thurn, an administrative head of the German wireless service, dismissed the stories as "so much nonsense," in an interview sent officially to Washington. He further stated that the correspondent who sent the dispatches to papers in the United States to the effect that in June a number of automobiles en route to Hamburg were halted when their magnetos were stopped by powerful radio waves from Nauen, was the victim of unscrupulous persons. "No such achievement has yet been anywhere reached," the German engineer asserted, adding that even if it had been attained by Germany, "it would have most certaily been kept a secret and not bruited about by anybody connected with Nauen."

This official information also discredits the stories that airplanes of France flying over Bavaria were stopped and forced down by radio waves from German stations.

Both stories of radio magneto control are impossible, according to the German radio expert, who pointed out that: Magnetos are enclosed in iron or steel jackets and could not be influenced by radio waves; no matter how powerful, radio waves cannot be directed with precision so as to affect the magneto of a vehicle or vessel at any distance from the directing station, particularly when the vehicle is in motion; and that are definite or precise directing cannot be achieved, every vehicle or vessel within the zone of influence of the electrical wave would be similarly affected. This would stop, bring down or sink the vehicles or ships of the operating agency as well as those of the enemy.

Some skeptics may believe that the Herr Administrator would have denied the statements in an effort to protect Germany's secret radio control, but the official forwarding the dispatches believes implicitly in this radio engineer, whom he knows personally and professionally, and he feels that his negations and criticisms should be taken without reservation.

An Anti-Interference Circuit

(*Concluded from preceding page*)

necting wire passes through the grounded partition on to the compartment on the other side.

The condensers, as I have said before, are the big items of expense in making this tuner, and therefore you should use care in purchasing the right kind as to quality. Nothing but very high grade condensers ever give satisfactory results in a radio circuit. There are plenty of good, high grade condensers now on the market and you will have little trouble to find one.

The coils in this circuit can be readily wound at home with No. 22 S.C.C. magnet wire. After finishing each coil it is advisable to shellac it, taking care to cover it with only a thin coat, since too much shellac increases the capacity of the windings, thus destroying sharp tuning. Now as to the specfications of the various units. You will notice that each group of inductances consists of two separate coils. The coil in the Ant.-Gnd. circuit is always wound on the larger size 4 inch tubing, while the coil on the other side of the circuit is always wound on the smaller size tubing (3½ inch). Of course, the size of the coil tubing can be varied slightly without any detrimental effect just so long as one tube is large enough to slip snugly over the smaller one in much the same manner as the two coils in the air core transformers used in the "neutrodyne" (called "neutroformers"). In figuring the length of tubing to cut off for each coil it is good to figure about 20 turns of wire to the inch for No. 22. Using the 20 turns as a basis, the tubing holding the coil L-1 and L-2 should be 3 inches long because L-2 has 40 turns of wire and allowing for end space 3 inches will be just right. Although the coil L-1 has only three turns of wire, it is wound on the same length of tubing as L-2 in order to make the ends of the two tubes fit flush when slipped over each other to make the complete inductance unit. The coils L-3 and L-4 are identical to L-1 and L-2, that is, the primary having three turns and the secondary 40 turns. The unit E-F is assembled in the same manner as the filter coils. It differs in that the coil E has 50 turns with taps for switchpoints at every fifth turn. The coil F, which is wound on the smaller size tube, has 50 turns, untapped.

The condensers C-1 and C-2 can be either 11 or 23 plate air variables, the 11 plate size being the better for this particular use. The condenser C-3 should be an 11 plate type with a venier, while C-4 should be a 23 plate condenser. It matters little how the movable and fixed plates of C-1 and C-2 are attached in the receiver, but the condenser C-3 should have the movable plates connected to the ground side of the filament-grid circuit. C-4 works better when the movable plate side is connected to the Ant. side of the circuit; that is, the fixed plates are directly connected to the plate of the tube.

Although I have shown the circuit with detector tube only, the circuit is easily adaptable for use with the ordinary two-stage amplifier. You are free to use any tube in this circuit you so desire as long as you select the proper size filament rheostat and grid leak and condenser to go with it. Do not try to work a 201-A tube with a grid leak that has been made or adjusted to work efficiently with the UV200.

Just a word about the 201-A tubes. I have been recently using these tubes as detectors and find that they give results equal to the 200 under all conditions provided the correct grid leak is used. Taking the fact into consideration that the 201-A is not as critical on the filament adjustment leads me to think that it is better as far as manipulation is concerned. Splendid results can be obtained with the new UV199 tubes in this receiver.

In tuning remember to set C-1 and C-2 at zero capacity. These condensers are used to tune out interference only and nothing else. The switch S is a D. P. D. T. anti-capacity switch (made by Federal Tel. & Tel. Co.) and is used to select the type of regeneration desired. If you fail to obtain regeneration when S is in the down position reverse the terminal connections to the coil F.

Commercial and Naval Radio Services to Japan Are Open

By Carl H. Butman

WASHINGTON, D. C.—The Japanese calamity, which practically wiped out Tokyo and Yokohama and broke the Pacific cable, gave radio another opportunity to demonstrate to the world its value of international communication, especially in the event of emergencies when land lines and cables fail. Without the single radio communication link left at Iwaki the world might have been without details of the Japanese disaster for as long as a week. Bits of news and imperative information would have been put through by cable, but radio is said by Secretary Hoover to have literally saved the day in bringing in relief as well as in carrying out the news.

To be sure, the first brief message of the disaster came to the Japanese Ambassador at Washington by cable from Nagasaki via London—out of the back door of the East, as it were, and over cables estimated 15,000 miles long. The Pacific Commercial cable from Japan to Bonin Island, reported submerged, and thence to Guam, was put out of service by the earthquake. Messages are now routed east via Manila, Shanghai and Nagasaki, or west via London.

It remained for radio to carry most of the official dispatches and news reports across the Pacific to North America, and radio, aided by the remaining cable connection of Nagasaki, has handled a tremendous amount of traffic. The Japanese government station at Iwaki, or Tomioka, stepped into the breach and the world now knows of the excellent service rendered by the Japanese operator who stood a long watch alone. His call and messages on the disaster were picked up by the Radio Corporation's station at Bolinas, Cal., and relayed to all points in the United States. Iwaki, which is about 144 miles from the stricken cities, for some time had no means of communcation. At the suggestion of the Japanese Ambassador at Washington, however, a courier service was established to Tokyo and now a regular schedule is in operation. A statement that communication was open to Tokyo, by the State Department, led some to believe that line wire communication between the station and Toyko was established. However, communication used in the old sense means that the roads were open. According to the latest reports no wires have been re-established. Since the advent of radio, it seems that a new word must be substituted for "communication" when referring to roads and other lines of transportation.

Radiograms are now accepted for all points in Japan, except Tokyo and Yokohama, being mailed from Iwaki. Messages for these two cities are subject to delay.

Radio was the means of getting the first authentic account of the disaster to the new world on September 4. The master of the S.S. "President Jefferson" radioed to his Shanghai office from the port of Yokohama direct. The American Consul put the message on the cable for Secretary Hughes in Washington. Facts relating the unsafe condition of the harbor at Yokohama were immediately broadcast by the Naval Hydrographic Office here that all ships might be warned of the hidden dangers there, the absence of lights, etc., radio again serving in its most valued capacity, that of protecting life at sea.

The United States naval forces in Japanese waters are rendering official emergency service via radio. The American Asiatic Fleet is now at Yokohama and the destroyer "Borie" is stationed at Nagasaki as a radio relay ship. Messages from the American flagship are

The transmitting station at Haranomachi, Japan, which gave the world the first meagre details of the terrible earthquakes. It was from this station that the operators broadcast all the later details, and was the only means of communication between Japan and the rest of the civilized world. All the cable systems were either ruptured, or put out of commission by having their shore ends destroyed in the stricken district. The transmitter is remotely controlled from the Tamioka station, which is 178 miles from Haranomachi. Both are considered as one plant under the name of the Iwaki radio station.

First American Built Dirigible Equipped with Radio

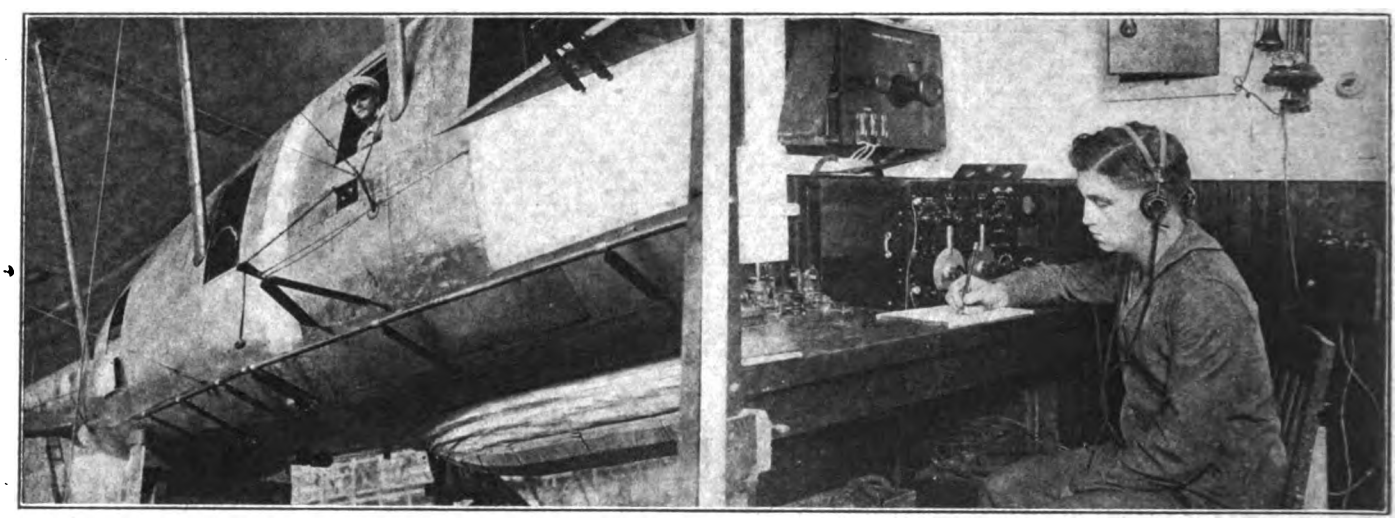
UP to the present time, the American aeronautic forces of the Army and Navy have not paid much attention to dirigible or lighter than air craft. However, there has been under construction by the navy at Lakehurst, N. J., the largest rigid type "lighter than air" craft that has been attempted in America. The only other nation that has attempted with success the construction of this type of airship is the German, famous for the Zeppelins.

The advantage of this type of aircraft in patrol and other work is the fact that it does not have to keep moving at all times but can remain stationary at different heights, or drift with the air currents. This gives the plots and observers greater chance to chart and observe the particular district over which they are flying. In airplanes this is so far impossible, as they have to keep moving. The ZR-1 is a most thoroughly equipped craft. It is capable of extremely long journeys, as the fuel used can be stored in the cupolas meant for that purpose and also because of its ability to drift with the varying currents of the air.

Paramount in its electrical installation, however, is the radio apparatus. The transmitter is a three KW. C. W. transmitter and an up-to-date navy type receiver, especially designed and built for this particular installation. Due to the fact that a trailing type of antenna is used, and the metal work of the dirigible is used as a ground or counterpoise, the receiver was designed especially for this type of work.

The initial flight of this monster of the air demonstrated its practicability, and during the series of successful trial flights, it kept in constant touch with its home base through radio, advising of the operation, speed and action at varying heights, thereby allowing the observers on the ground to accurately note its action from a distance.

Radio in airplane flights is a past performance, but this is the first time that an American lighter than air craft has been equpped with radio, especially as powerful an apparatus as that installed in the ZR-1. This power and its especially constructed apparatus will enable it to send and receive over much longer distances than has been done heretofore by airplanes, which are naturally limited as to space, and therefore cannot install powerful apparatus, which takes up space and is heavy.



(C. Both photos Kadel and Herbert)

The radio gondola of the dirigible ZR-1 showing the trailing antenna, with the heavy weight attached to prevent its flying back and entangling itself in the controls. John T. Robertson, radio operator of the ZR-1, observing the camera man at work. Current for the operation of the powerful transmitter is derived from a wind driven generator located at the fore part of the radio gondola.

The home station of the ZR-1 at Lakehurst, N. J., receiving reports from the craft while it was in the air. The receiver is the latest type naval apparatus, comprising three stages of radio-frequency, detector and two stages of audio-frequency. The transmitter is remotely controlled by means of relays, and this station and the ZR-1 during flight are constantly in communication.

(*Concluded from preceding page*)

picked up by the "Borie," relayed to the naval radio station at Cavite and thence to the naval station at San Francisco. Government west bound messages are sent from Washington via Annapolis radio station or commercial land lines to San Francisco, where they are relayed via Honolulu, Guam and Cavite to the "Borie" and thence to the American fleet off Yokohama. The U. S. S. "Sacramento" is stationed at Woosung, China, to relay radio messages.

Many radio experts feel that the terrible disaster and the severing of communication out of Japan will aid materially in establishing better radio service between Nippon and the world. The policy of the Japanese government has been to control radio, although American commercial companies have been endeavoring to provide better stations and transmission.

Is It Home-made Static?

NOW that the cooler weather is coming on, lots of fans expect a decrease in static and are much disappointed when they do not find it so. Do you realize that noises exactly like static, and probably louder and longer are often caused by faulty B batteries? To test it out, turn off your detector tube, stick your jack in the last tube of your amplifiers, and turn on your amplifier tubes full. You will then discover just where your "static" is coming from. The remedy, of course, is to find out just which set of batteries is causing the disturbance and to remove them.

One Thousand Amateurs at A. R. R. L. Chicago Convention

THE second national American Radio Relay League convention opened at Chicago on September 12 with a registration of approximately 1,000 delegates.

The banquet in the evening at the Hotel La Salle was splendidly attended. An inspiring message was read from Hiram Percy Maxim, president of the league. Addresses also were made by other officers and members of the board of directors, as well as by officers of the Chicago Radio Traffic Association who are directing the affairs of the convention. Another prominent speaker was W. D. Terrill, chief supervisor of radio, Department of Commerce.

The diners enthusiastically welcomed the distinguished French radio amateur, Leon Deloy, and A. H. Krussell, a Canadian amateur. The convention, therefore, took on an international aspect, a most encouraging development.

Dr. Lee De Forest, the eminent radio pioneer, is returning to the United States on the S.S. "Leviathan." The delegates cheered the reading of the following message from Dr. De Forest, which was radioed from the "Leviathan" to the banquet hall:

"Radio will have a continually expanding influence on the welfare of the world. It will make people happier through its entertainment utility, healthier by its spread of information, and better through its power to promote understanding."

Major White Gives Dempsey a Lesson in Radio

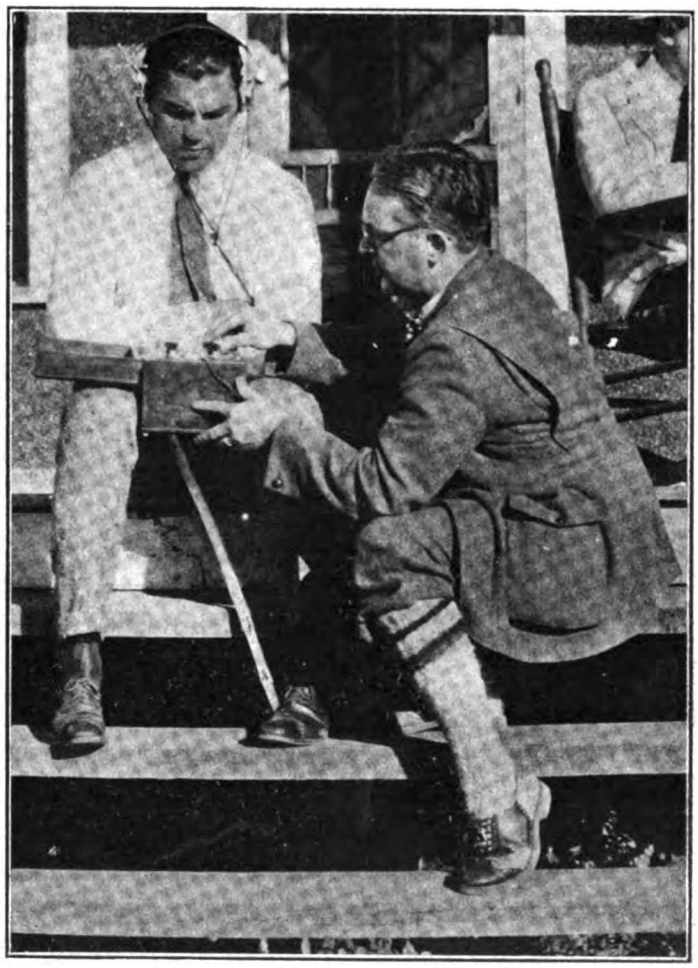
MAJOR J. ANDREW WHITE, who broadcast the Dempsey-Firpo fracas recently held, visited Jack's training quarters at Saratoga a few days before the fight and showed him how to work a portable receiver of the type that hundreds of interested fight fans and broadcast listeners would use to hear the ringside returns that Major White was to announce from the ringside.

Dempsey, while not a fan himself, understands what it means to thousands of fight fans and listeners who would not be able to get to the championship battle, to hear a blow by blow account of the fight, told in Major White's interesting and terse manner.

Another point of interest in the fight is that thousands of South American supporters of Firpo had sets installed so that they would be enabled to hear the instant returns of the battle.

The illustration shows Major White instructing and explaining to Jack the why and wherefore of the different dials on the Aeriola, Sr., that he is using. It is not stated whether Dempsey assimilated the technical explanations as well as he can interpret a left hook to the jaw followed up by a right cross to the bread basket, but by his expression it evidently puzzles him.

In the large cities thousands of people who could not get to the fight and who did not own sets, stood outside radio stories that had loud speakers and got the returns "hot off the griddle."



(C. Radio Corporation of America)
Major J. Andrew White Explains a Radio Set to Jack Dempsey

To Save Money

MANY sets use potentiometers across the A battery leads of the first tube, on the battery side of the rheostat. When you turn off for the night you simply turn out your tubes and forget about it—unless you are wise. Then you realize that your battery is constantly discharging across the potentiometer all night and you disconnect your battery leads from the set altogether. Four hundred ohms is a lot of resistance, but even at that it will shorten a battery's life considerable by leaving it in the circuit.

MacMillan Party Safe

A PRESS dispatch from Prince Rupert, British Columbia, Canada, states that Captain Donald B. MacMillan, Arctic explorer, and the members of his expedition who sailed from Wiscasset, Me., last June aboard the auxiliary schooner "Bowdoin" are well and safe at Etah, on the northwest coast of Greenland, according to a radio message picked up there by Jack Barnesly, an amateur operator.

The "Bowdoin" will winter at Flagler Bay, the message said. A foot of snow was reported.

Radio Successfully Aids Aviation

By Carl H. Butman

WASHINGTON, D. C.—Radio, the latest "wonder of the world," is materially aiding the development and efficiency of military and naval aviation. War-time flying in its many phases, would avail little to the commanders-in-chief if instantaneous communication between the bases and the air fleets was not constant. Radio telegraphy and telephony establish direct liaison between the air and the ground or sea, thus combining these arms of the service.

Peace-time tests and maneuvers between the aerial forces and those of the land and sea aided by radio are carried on regularly by both the army and navy; their scope and frequency are being extended each year.

A recent army air service report from France Field, Canal Zone, states that during the past fiscal year 261 radio flights were made, embracing aerial radio tests, voice-controlled formations, coast and field artillery reglages or gun-fire observations, tactical maneuvers, reconnaissances and coast patrol work. This was an average of a radio flight each working day. The diversity as well as the volume of radio communication accomplished in the Canal Zone was in excess of any previous year but will be extended next year, the report states. France Field pilots had never before attempted tactical maneuvers, coast patrol, field artillery spotting or voice-control formation flying, yet the report indicates successful results in all lines where radio was used.

More radio test flights are necessary, the report recommends, as constant testing is the only means of keeping radio equipment in first-class condition, particularly under the severely corrosive climate of the tropics. Furthermore, the training and experience of pilots through regular use of radio is held of utmost importance. Following maneuvers with the naval fleet and demonstrations at Balboa Flying Field, weekly voice-control flights, in which the pilots receive their instructions and orders by radiophone from their commander in the air or on the ground, were recommended in order to improve and train the flying personnel in airplane tactics and radio communication.

Coast artillery spotting held last fall proved far superior to any held in the Canal Zone, not only in point of reliability and efficiency of two-way radio-telephone communication, but also in the extension of the ranges at which this two-way radio communication was carried on. The Air Service, called upon by the Coast Artillery Defences of Cristobal and Balboa to spot their fire for three coast artillery stations, carried out 49 radio-telephone flights, all of which, according to the coast artillery, were eminently successful.

The first attempt to use two-way radio-telephone to spot firing for the field artillery was at Gatun. A radio operating truck, type SCR-108, was sent to Gatun and used as a mobile ground station. This truck was connected by field telephone lines with the battery commander's station direct. The results were very satisfactory and highly commended by field artillery officers. Four field artillery officers were utilized in spotting fire from the air. After 30 minutes of instruction in the use of the radio telephone they were qualified to operate the radio-telephone set in the airplane during the flight and adjust the fire of their battery.

The value of radio-telephone communication in giving and receiving instructions in the air was clearly demonstrated when France Field sent all of its planes and flying personnel to the Balboa Flying Field for inspection and maneuvers. The success indicated what should be expected with more improved radio telephone and telegraph sets operating with ground radio sets of higher power, it is stated officially.

During the U. S. Navy maneuvers in Panama Bay, the air service was called upon to do special reconnaissance work and to patrol the Pacific Coast for a distance of almost 100 miles to the southwest. That two DH4B airplanes, equipped with SCR-73 spark sets were able to send position reports in the air from Aguadulce, Panama, a distance of approximately 80 miles, to the France Field radio station through interference, was a feat never accomplished before. SCR-68 radio-telephone sets on Martin bombers successfully sent position reports on two occasions by voice and buzzer modulation from Pearl Islands to France Field, a distance of almost 100 miles. The SCR-73 spark sets, it is believed, could send from the air to France Field, approximately from 150 to 200 miles, without much trouble. When installed on Martin bombers they should approximate a range of about 300 miles, it is estimated.

United States Radio Conferees Announced

THE United States committee of electrical and radio experts representing eight governmental departments having to do with radio and other electrical communications has just been announced by the State Department. This committee, headed by Under Secretary Phillips of the State Department, will meet at an early date to consider the plans and policies of this Government on matters pertaining to international electrical communications.

The agenda prepared by the committee will become the basis for the United States' report to the Fourth International Electrical Communication Conference when it is held in Paris. It is probable that the American delegates to the International Conference will be selected from the personnel of the committee, but as no date for the general conference has been set, the State Department has not made announcement of its representative or plans. The international conference was to have been held this spring but was indefinitely postponed. The United States governmental representatives are: State, William Phillips, Under Secretary, Chairman; Treasury, Lieut. Zeusler, U. S. Coast Guard, and Constructor Walton, alternate; Army, Maj. Gen. George O. Squier, Signal Corps, and Maj. W. E. Prosser, alternate; Postoffice, Second Asst. Postmaster General Paul Henderson; Navy, Rear Admiral W. R. Shoemaker, and Commander D. C. Bingham, alternate; Agriculture, W. A. Wheeler, and E. B. Calvert, alternate; Commerce, Solicitor S. B. Davis, and P. E. D. Nagle, alternate; and U. S. Shipping Board, L. L. Lee.

A Simplified Flewelling Circuit

By Le Roy Western

TO those interested in super-regeneration and circuits giving a similar effect to the Armstrong super-regenerator, the Flewelling circuit offers quite a large and interesting field for experiment. The writer has done a considerable amount of work along these lines, starting with the three-condenser Flewelling which was first brought to the attention of the radio public and then working along lines more or less original with himself.

The diagram herewith shows one of the most flexible circuits, in the writer's opinion, which makes use of the unique condenser arrangements for obtaining a variation frequency. This set, as will be seen, is exceedingly simple in construction and instead of the usual bank of three condensers, makes use of only a single fixed condenser. This latter is not very critical as to capacity and the writer found that capacities of from from .003 to .006 mfd. gave excellent results.

The grid condenser and leak should be given a great amount of attention and should be carefully selected. The condenser may, if desired, be fixed at a capacity of about .00025 mfd. but much better results will be obtained if a good standard make of variable condenser with a maximum capacity of .0005 mfd. is used. The grid leak should be constantly variable from one-half to five megohms and should be of very good construction in order to eliminate loose contacts and other objectionable features which would tend to cause noises in the circuit. Any extra time which may be spent in the construction of this variable grid leak will not be wasted as the results will amply repay the builder.

In regard to the tuner, the author would advise the use of two honeycomb coils, coil P having from 50 to 75 turns wound thereon, while coil S should have at least 100 turns. If in the course of construction, the builder finds that he does not have honeycomb coils of the required size, a standard variocoupler may be impressed into service and rewound so that the primary has about 75 turns, tapped every 10 turns for its entire length. In this case the rotor should also be rewound so as to contain approximately 100 turns. In the case of honeycomb coils, the primary coil P should be shunted by a small variable condenser with a capacity of approximately .0005 mfd.

In one of the writer's experimental sets, a standard variocoupler was used without rewinding. In this case, it was found advantageous to connect a variometer in series with the rotor as indicated in the diagram herewith. If, however, honeycomb coils are used or the variocoupler is rewound, it will be unnecessary to use a variometer, although the builder is advised to experiment with the connection in order to ascertain just what will give the best results.

A switch arrangement at A and B was installed by the writer when using the Flewelling circuit so as to afford flexibility in connections to the primary. By means of the two single-pole double-throw switches, it is possible to connect both the aerial and ground to the coil P, or to use the ground or the aerial alone, and to connect either one of these to either side of coil P. This afforded extreme flexibility in experimenting with the set as it was unnecessary to undo connections in order to find out just where the aerial or ground should be connected. It was found that when either one was to be used alone, best results were obtained when it was connected to the side of coil P which is in turn connected to the grid. In some cases it is possible to use both antenna and ground on this set although usually excellent results are obtained with the former alone.

The tube used in this circuit should be of the hard variety, although the WD12, UV199 and UV201A will all give excellent results. The "A" battery voltage will depend entirely upon the tube used and the "B" battery voltage should be experimented with in order to find out what value will give the best results.

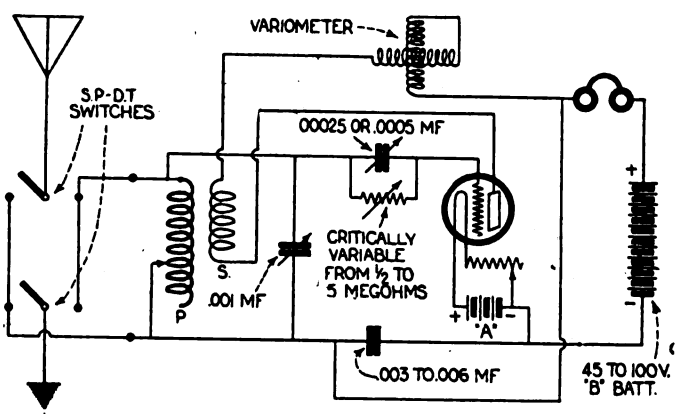

Diagram of Western's simplified Flewelling circuit.

After this set is connected as shown, light the filament and place the grid leak at a value of approximately 1½ megohms. By adjusting it will be found that a shrill note will be heard in the phones. This note can be changed by varying the tickler and grid leak. These should be continuously varied until the note is as high as possible and then a station should be tuned in by means of the variable condenser. The high shrill note will not be objectionable once the operator gets used to it. If a signal is once heard, all the adjustments should be varied until best results are obtained, paying particular attention to the adjustment of the variable grid leak.

For a one tube set, the outfit described above will give extraordinary results and will furnish opportunity for a considerable amount of interesting experimentation.

Now Is the Time

ARE you thinking over the wonderful results that your friend got on that new receiver he built last spring, and with which he corralled all the distance all summer? Well, now is the time to build it—just in the interim between the hot summer and the cool winter months. Go right ahead and build it and try it out now, so that when the DX weather gets here you will be right up with the rest of the bunch and not miss any just because your set "is not built yet."

If You Are Wise

IF you are wise and in the know you will build your detector and two-step amplifier unit in a separate cabinet from the tuner and well shield it. Then bring all your connection posts, such as grid, plate, filament, etc., out to binding posts on the back of the cabinet and make connection to your tuner through these. By doing this you will be able to change your set around at any time, and use different tuning systems without disturbing the cabinet containing the amplifier and detector.

RADIO PRIMER—For the New Army of Radio Beginners

By Lynn Brooks

INDUCTANCES: In radio reception as well as transmission, some means for varying the frequency to which the receiver or transmitter will respond has to be evolved. In order to cover this from the receiving end tuners are used. The simplest tuner consists of a coil of wire wound on a suitable tube or former, the value of which is varied by means of a slider. This inserted in the antenna-ground lead of the receiver allows the receiver to respond to the different wave lengths due to varying the frequency value of the circuit. The greater the amount of wire used, the lower the frequency the receiver responds to and the higher the wave length. This is similar to a violin string. The longer the string, the deeper the tone and the longer and slower the sound waves.

The main disadvantage of a tuner made of a coil as described, is the fact that it is not selective. It will not respond to one frequency sharply, but responds to several bands as well. The next tuning device of the single inductance variety is the variometer. This depends upon the mutual inductance of two coils revolving within one another and connected together. As we vary the relation of the magnetic field we also vary the mutual inductance, due to the principle that two coils through which a current is flowing are at their highest point when the current runs in the same direction in both coils. As we vary this, instead of helping they practically "buck" each other.

The next important tuning device is the loose coupler or variocoupler. This consists of two windings so arranged that one can revolve or slide in and out of the other. In the loose coupler, the outside winding is generally considered the primary or antenna inductance and its value is varied by means of a slider or taps. The secondary or inside one is variable by means of taps or a slider, and can slide in and out of the magnetic field of the first. This arrangement allows sharp tuning, because the primary circuit does not interfere or have any connection outside of a magnetic one with the secondary. The current flows through the first or primary coil, which as before stated is varied as to inductance value by means of sliders or taps, introducing more or less wire into the circuit and therefore the circuit will respond to a higher or lower frequency. The current flowing in this circut induces a like current in the secondary circuit, which is also variable, and by means of sliding this in or out of the magnetic field, the best point of resonance can easily be gained, at which point the two circuits will be considered "tuned" and the strongest signals from a desired station will be had.

In the coupler of the later variety, the same principle is used, with the exception that the secondary coil is not variable as to the amount of inductance used, tuning being accomplished by varying the mutual magnetic inductance between the two. The secondary coil of these couplers is variable through 180° inside the first, coupling being accomplished by this means instead of sliding it in and out. In the latter type, when it is found desirable to gain variance of this secondary coil, it is shunted by a capacity which is variable, and the inductance value is raised or lowered by varying the capacity in the immediate circuit.

Fixed inductances used to form couplers of different types come as duo-lateral, honeycomb or spiderweb. The advantage of each of these is the fact that the distributed capacity between adjacent turns is low. In the first type this capacity contributes a great deal to the inability of the apparatus to tune sharply . This is due to the fact that one turn with its insulation forms a condenser with the next turn, the entire winding resembling a coil with a constant capacity across it.

THE REASON FOR INDUCTANCE: Many people when examining a receiver do not understand just why coils should be used in the circuits. Take as an example two stations sending. One will send out on a wave length of 500 meters (frequency value 599.6 kilocycles). Then the second we will suppose will send on 400 meters (frequency value 749.6 kilocycles). Now should we desire to receive the one on 500 meters, we should introduce enough inductance or inductance and capacity into our circuit to enable our receiver to respond to or approximate the frequency value of the desired station. This is seen to be 599.6 kilocycles, which means that the alterations or waves emanating from the transmitter make 599,600 complete reversals per second. When our receivers respond to this frequency we have the station tuned in and we hear the voice or signal. Now should we desire to hear the one on the lower wave length, we must arrange our receiver to respond to a higher frequency. Analogy: The shorter the string of the violin, the higher the tone, the shorter the wave vibrations, but the faster. Therefore, we remove some of the inductance from our circuit and when our circuit will respond to 749,600 cycles per second we have succeeded in tuning our receiver to 400 meters.

No Broadcasters Licensed

FOR the first time in many months no new broadcasters sought licenses for stations during the week ending September 8. This is a confirmation of predictions of Secretary Hoover, and his radio aides, that the saturation point has really been reached. That 567 were enough broadcasters, nearly everyone agreed last month, and so few regret that the number has fallen off four. The point now established is that evidently those who contemplated entering the field also recognized this fact and refrained from taking out licenses. The activity this month is the least since February, 1922, which indicates a better state of stability in the broadcasting field.

During August seven new stations came into being, thirteen transferred from Class C to Class A, and eleven ceased operation. This leaves the present number of broadcasters at 563 stations, a large percentage of which are good, reliable stations, likely to survive.

One Class B station, well-known WGY, transferred from its classification to Class D, covering broadcasting development, and now shares this honor with Pittsburgh's KDKA.

Tests on Radio Transmission by Day and by Night

Effect of Light and Darkness on the Energy of Radio Waves

MEASUREMENTS of the energy of radio-transmission between Rocky Point, Long Island, and London, made last winter by cooperation between the Radio Corporation of America and the American Telephone and Telegraph Co., bring out some interesting facts, reported by Ralph Brown, of the telegraph company to the National Academy of Science and printed in its Transactions. The tests show that the energy of the transmitting wave is about eighteen times as great in the middle of the night as it is in the daytime. This difference, however, lessens in the summer when the nights are shorter. It appears to be due to the fact that obstacles resulting in absorption are fewer by night than by day. A typical example of the strength of the waves as they reached England is given in the diagram herewith.

When daylight covers the entire transmission path from Rocky Point to London the field is uniformly low but during the night it rises to considerably higher values. At night the field is relatively steady and free from fluctuations of the kind ordinarily known as "fading," but the general shape of the curve may change from night to night as is indicated by the dissimilarity between the two dark periods shown.

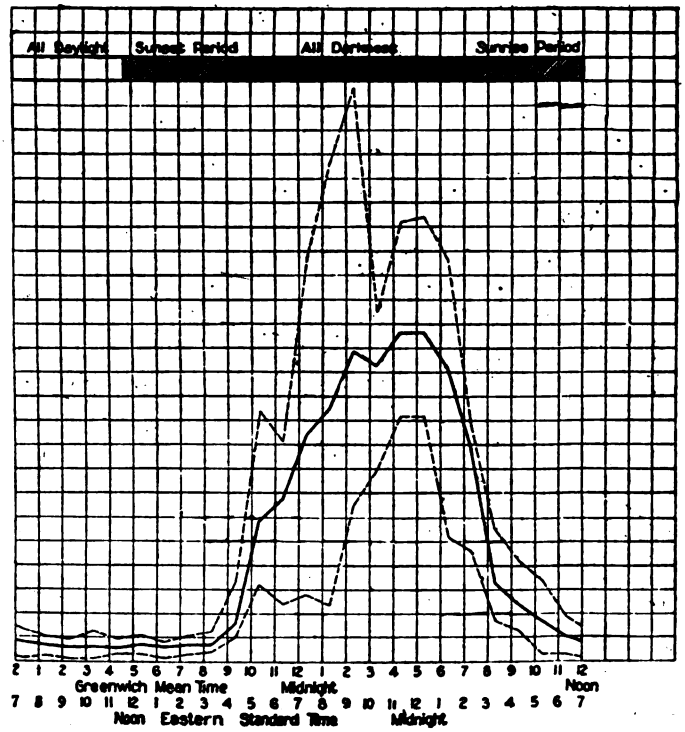
The outstanding thing shown is that the high night values are practically as steady as the day values and have no greater percentage variation from the average. The improved night transmission is a definite recurring phenomenon which may not properly be called a freak transmission effect.

In accordance with the usual theory of radio transmission the decrease in strength of the electric waves, as they pass outward to the distant receiving station, is caused by the spreading of their energy over a larger and larger circle of wave front and by losses due to the electrical imperfections of the media traversed.

One characteristic of these winter-time data is worthy of note. The average night values are eighteen times as large as the average day values and rise about halfway up the field which would be obtained if there were no absorption loss in the transmission media, yet, not even the maximum recorded field shows any tendency to exceed the theoretical value for transmission without absorption loss. This evidence falls easily into line with the theory that good night transmission is simply due to a diminution of the absorption losses.

During the last days of February a radical change occurred in the nature of the night transmission phenomena. The reason for the suddenness of the shift is unknown, but a decrease in the night field is consistent with the fact that the period of darkess over the entire transmission path is only about 6 hours on April 1, as against 10½ hours on January 1.

Of the ten hours winter night, six hours are spent in rising to and falling from the high values, which are steadily maintained only during a four-hour period. When the time of darkness over the entire path decreases to six hours or less the peak might be expected to be wiped out.



Curves showing how the energy of the transmitting radio waves varies. The dotted lines indicate minimum and maximum energy. The heavy line is the average for 54 days.

Making Use of a Nuisance

THE owners of regenerative sets regard body capacity effect as an absolute nuisance. However, it may be used to serve a very useful purpose. By its use, it is possible to tune a station in to the exact point where reception is at its loudest. When tuning a set, using a vernier, it is hard to tell when the station is coming in at its loudest, as a small change in volume is hard to detect, although this same small change would perhaps be useful in getting the call letters of a station after it has begun to fade.

In the first place, the fixed plates of the condenser should be connected to the grid of the tube. Shielding is then unnecessary. This reduces body effect a great deal. What is left may then be used for accurate tuning. Proceed as follows: Tune the condenser until reception is at its loudest. Then remove your hand from the dial. If the volume of the signal decreases, increase the capacity of the condenser slightly. Repeat this, until when you take your hand away, there is no decrease in volume. If when you first take your hand away, the volume increases, you can usually get it slightly louder than this by reducing the capacity of the condenser until there is no change in volume. This plan is more valuable when the station is coming in weak rather than loud, when a slight change in volume is hard to detect.

Combining Regeneration with Tuned Radio-Frequency

By R. L. Dougherty

IN RADIO WORLD for August 11 there was described a method of combining tuned radio frequency in a set in such a manner that it could be rightly called a "Universal" receiver, inasmuch as it would receive over all wave lengths from 180 to 25,000 with equal ease.

While fair success could be had with a receiver of this sort, the present day fans are so accustomed to the use of regeneration in connection with their receivers that they scorn to tackle one that does not combine it in some form, as being beyond the pale. In a way they are right, as regeneration makes remarkable distance possible. But when combined with a receiver of the sort shown in which feedback coupling is had through the radio-frequency tube, there is a liability that the ticklishness of the receiver will cause plenty of "howls" if the receiver is not tuned just right.

The constants of the receiver remain practically the

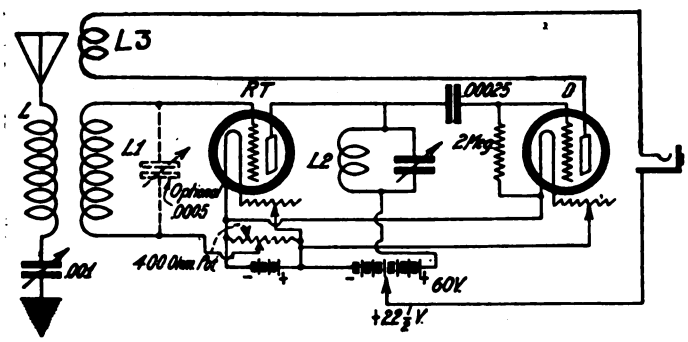

Fig. 1. Circuit diagram illustrating how you can add regeneration to the tuned radio-frequency receiver described in RADIO WORLD, August 11. By inserting the feed-back coil (L3) the advantage of regeneration is added to the circuit, combining the distance possible with radio-frequency with the sharp tuning of a regenerative circuit. Being a double circuit it is selective and flexible. The constants are identical with those of the August 11 circuit, with the addition of the feed-back coil.

same as that of the aforementioned receiver, with a triple honeycomb coil mount used for the primary, secondary and tickler. You can therefore really call this an accommodation of the three-circuit regenerative receiver with a stage of tuned radio-frequency amplification. The addition of regeneration to the receiver can easily be made if the first set has already been constructed, as all that will be necessary is the breaking of the plate lead that goes to the phone and the insertion of the third or tickler coil in the circuit.

For the edification of the fan who is sceptical as to the efficiency of the "tuned impedance" type of radio-frequency, it might be of value to state that there is no form of radio-frequency amplification as popular with the fan who wants real selectivity as that particular form. The fan who knows by experience, won't tackle anything but tuned radio-frequency, simply because of the extreme selectivity it affords. It is no exaggeration to state that a difference of four meters in wave length between two stations is sufficient to render either one of them inaudible when the other is tuned in.

By employing regeneration in this circuit, a bit of the selectivity may possibly be lost, but not so much that you will be bothered with anything like broad tuning. The detector tube cannot respond to anything but the wave that the radio-frequency circuit is tuned to, so for that reason I advocate that all fans who have enough experience in the operation of a receiver should use tuned radio-frequency, leaving the transformer coupled for those who do not mind whether they get selectivity or not. As a matter of plain fact really sharp tuning with transformer coupled radio-frequency is not only impossible—it is foolish to even expect it.

Take into consideration the fact that you must tune your primary circuit in order to receive signals. To do this you vary the inductance, or the capacity, either shunting or in series with the inductance, or both, whichever may give you the best tuning. After passing through the radio-frequency tube the impulses that originally passed through the antenna circuit are identically the same—they have not changed one bit. Why not tune your radio-frequency amplifiers the same way? When using the transformer this is impossible because the windings cannot be varied, nor will shunting capacitances across them give any real tuning or help.

Page after page could be written enumerating the advantages of tuned radio-frequency, both as to theory and practice, but as this is not meant to be an article of that type the aforementioned advantages should be sufficient to convince anybody that for real tuning selectivity, where radio-frequency is concerned, the only way of approaching the subject in the correct manner is to use some means of tuning your radio-frequency amplifiers.

When constructing the receiver it is imperative that the entire panel be shielded very carefully. Ground this shielding. Also see that the rotary plates of the condenser in the primary circuit are connected to the ground. The condenser across the tuned impedance coil should be affixed to the panel by means of extension rods so as to keep it at least two inches in back of the panel. This can be done by the use of a sub-panel back of the main panel, and using a fiber rod to manipulate it. This is illustrated in Fig. 2. If the optional condenser is used across the secondary, it also should be mounted on a sub-panel 2 inches in back of the main panel, using an extension rod for manipulation. This is because both regeneration and radio-frequency is used. If these two condensers are not mounted in the manner explained it will be almost an utter impossibility to hold a station if the hands are taken away from the controls once it is tuned in—due to the metallic shafting.

Wire the set very carefully according to the diagram, using the varnished cambric tubing or "spaghetti" wherever leads cross at close quarters, and making the leads on the tuned impedance circuit as short as it is humanly possible for you to do it. An easy manner of accomplishing this is to mount the honeycomb mount for the coil L2 on the same sub-base directly under the condenser. Then by using binding posts on the back of the base, the battery and tube connections can be made as short as possible, and you will not have to run your leads all over the panel.

When tuning the receiver it will be found necessary to change the tuning of the circuit L2 by means of the condenser for every change in tuning in the primary

Digitized by Google

circuit unless the station is on the same wave length. After handling the receiver a week or so, and becoming used to its "rinktums," you can chart the wave length that the tuned impedance circuit responds to for definite settings of the condenser shunting it and for definite inductances used.

In operating the set turn on the two tubes to normal brilliancy and, selecting an arbitrary value for your L2 circuit, manipulate the primary, secondary and tickler much the same as you would were you using the regulation three-circuit honeycomb circuit. When a station is heard leave the primary circuit as it is and manipulate the circuit L2. Generally the signals will respond with a suddenness that is surprising, and if the condenser is not turned carefully you will run right over it, so for that reason it is a good idea to incorporate a panel vernier button for use with the circuit. Then, after hearing the call and desiring a station of lower or higher wave length, either more or less capacity is used in that particular circuit. Retune your primary, secondary and tickler controls until the station is heard. Then, after tuning your L2 circuit, increase the coupling of your secondary and tickler until the station comes in thickly—then clear it up with the potentiometer, lastly retuning your L2 circuit for maximum signals.

The circuit shown is easy to work once you get the hang of it, but there is a great deal of fine tuning that will have to be done before the signals will be tuned in correctly, so for that reason do not get impatient if you do not succeed in tuning in KYW the first night that you work it, even though the local stations may be comparatively easy to tune in and through. Learn how to do it exactly on the local or nearby DX stations before trying the real DX and you will become so used to manipulating the controls that you will instinctively tune the set simply by the "feel" of the air.

The circuit is especially adapted to the new UV199 tube because no storage battery is necessary, and also because these tubes are such marvelous radio-frequency amplifiers. You will be surprised at the volume possible with this circuit on cool winter nights as well as the distance that you can cover with it.

For broadcast work the coils for circuit L2 should be 35, 50, and 75. These will allow the receiver to cover all the broadcast waves efficiently. For the lower stations use the smaller coil, for the medium station use the larger coil, and for stations operating around 600 use the largest. If amateur stations are desired it is good to incorporate a 25 in the outfit also. It will take but a few minutes to find out which coil should be used in the L2 circuit for each band of wave lengths. For the primary, secondary and tickler circuits the regular honeycomb coils that are generally specified for a given wave-length should be used. However, for the information of those planning to build this receiver to respond to broadcast waves, it is safe to recommend that they purchase two each of the coils stated above and by changing them around in various positions in the mounting they can strike the happy medium. It is always best practice to use a smaller value of secondary inductance than that used as a tickler.

Care in construction, carefully soldered leads, and good panel material carefully shielded will repay the builder by surprising distance and tuning when the DX months come along. Then if it is considered necessary an additional two-stage amplifier can be added and loud-speaker operation is in order for all stations that can be heard on the detector.

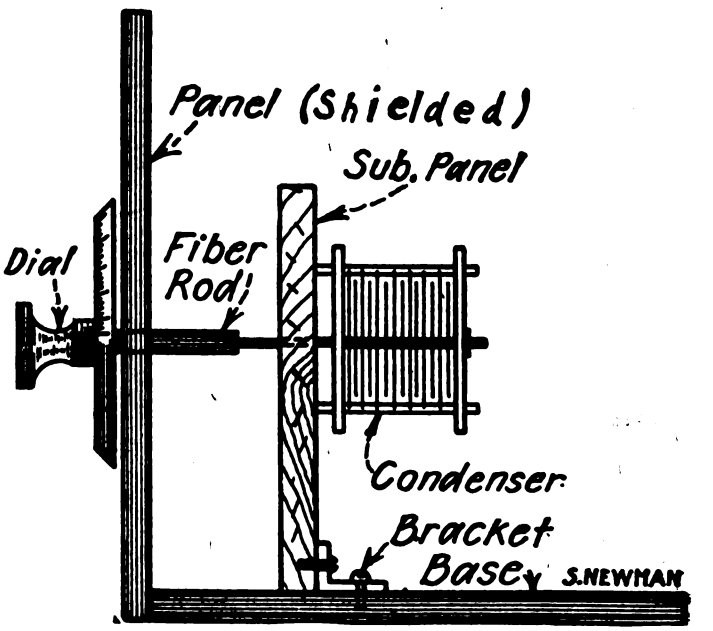

Fig. 2. Showing how to arrange the condensers on a sub-panel in back of the main panel to reduce any possible chance of capacity effect being felt. The sub-panel may be of well-dried hardwood, or small panels of hard rubber or bakelite. A space of two inches should be allowed between the panel itself and the sub-panel.

Retrieving Fading Stations

By Byrt C. Caldwell

WHEN the DX stations begin to swing and gradually fade away, most fans frantically begin to twirl the dials in the foolish belief that they can in this way regain the station. After a few minutes, they succeed in again tuning in the station, but the announcer has given the call letters, and more music is being played. Then it fades again and the process of losing the station is repeated. The fan usually succeeds in not succeeding in getting the precious call letters. Although, by leaving the tuning strictly alone, the signals will usually swing back again, it is often possible to coax them back. It is, of course, impossible to make them swing back. However, the fan seldom has his set tuned for maximum sensitivity.

When the signal fades, if it does not disappear to the extent that it is impossible to hear speech, leave the set alone, but if it fades until it is no longer audible, or is merely a whisper in the phones, tighten the coupling of the set until it just begins to howl. Then very carefully, with the accent on the very, loosen the coupling. This will often bring the station in again, and when the signals swing in they will be louder than they were in the first place. In this condition, the set is wonderfully sensitive, so sensitive in fact, that it is liable any moment to "spill over." In this case loosen the coupling until the set stops howling.

This plan is only adaptable to those sets which use a tickler feedback, or which have some means of controlling the regeneration. (See RADIO WORLD, September 1, page 15).

Characteristic Curves of Vacuum Tubes and Their Meaning

By J. E. Anderson, M. A.

ALTHOUGH articles on the characteristics of vacuum tubes appear from time to time in various radio journals, there still seems to be a demand for more, at least if the number of questions that are asked daily by radio fans is to be taken as a criterion. The questions that are most frequently asked concern the various means for maintaining the grid at the proper potential with respect to the filament, such as the grid biasing battery, the grid and plate potentiometers, the grid leak and the filament vernier rheostat. In view of these questions it will not be amiss to call attention to the characteristic curves and some of the information they contain.

The most important of the characteristics of a vacuum tube is the relation between the grid potential with respect to the filament and the plate current. A study of this relation will answer all the questions referred to above. In order to have a visual representation of this relation it is usually plotted on a sheet of cross section paper, using the plate current expressed in milliamperes as ordinates and the grid potential expressed in volts as abscissæ. Fig. 1 shows a set of the resulting curves, taken for four different plate potentials and covering a range of grid potentials of 60 volts, 30 volts on each side of zero or the filament potential. These curves will be better understood after an explanation of how they are obtained.

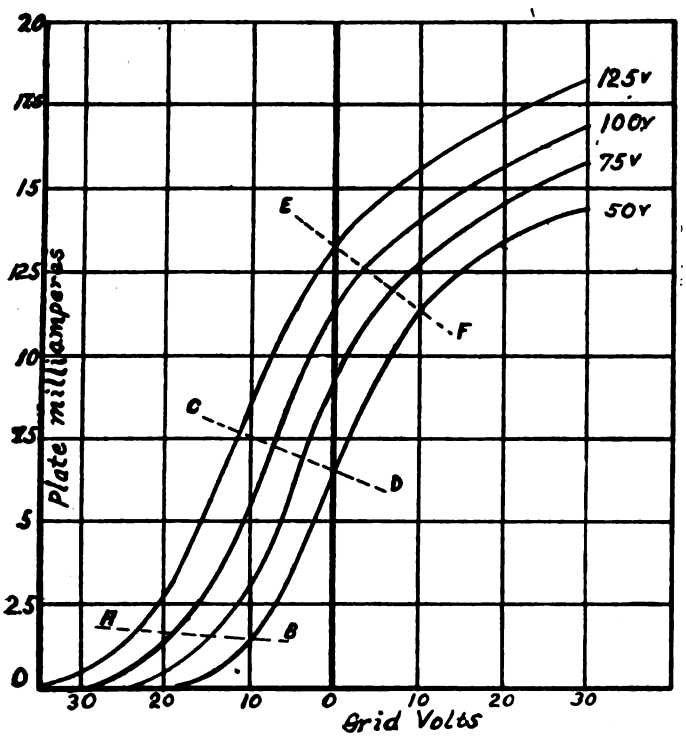

Fig. 1. Typical graph plotted for a vacuum tube at differing plate potentials, showing the relation of the plate current to the grid potentials. Charts such as these are the result of the experiments outlined in the accompanying article.

Fig. 2 shows the circuit used to obtain the curves of Fig. 1. It is typical of many vacuum tube circuits that are in daily use in radio receivers. B_1 is the grid battery which determines the grid potential, and B_2 the plate battery which determines the plate potential, both being measured with respect to the filament. V_1 and V_2 are voltmeters with which the respective voltages of B_1 and B_2 are measured. A is an ammeter with which the filament heating current is measured, and M is a milliammeter with which the plate current is measured. The data desired are the readings of the milliammeter and the corresponding readings of the grid voltmeter, while the filament current and the plate potential are kept constant at some desired values. The procedure is as follows:

The voltage of the plate battery B_2 is first adjusted to some desired value, say 50 volts. Then the filament is lighted and the heating current adjusted to the proper value. With the aid of the instruments A and V_2 these adjustments are carefully maintained during the run. Now the voltage of B_1 is increased, with the negative terminal toward the grid, until no current flows through the milliammeter. Then the voltage is gradually reduced, in steps of about three volts, and the corresponding reading on the milliammeter observed for each value of the grid potential. When the voltage in B_1 has been reduced to zero, the grid battery is reversed, so that the positive terminal is toward the grid, and then it is gradually increased until the entire battery is in the circuit, while readings are taken of the plate current for each value of the positive grid potential. When this run has been completed, the data are plotted on cross section paper, and the lowest curve in Fig. 1 is obtained. Now the voltage in the plate battery is increased to some other convenient value, say 75 volts, and the process is repeated for the new plate potential. Thus the second curve in Fig. 1 is obtained. The other curves are obtained similarly.

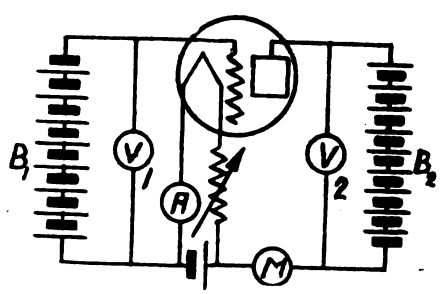

Fig. 2. Diagrammatic circuit of the apparatus used to plot the curves shown in Fig. 1. The apparatus and its manipulation to obtain the characteristic curves is described herewith, giving the reasons for each adjustment.

By studying the curves in Fig. 1 it is seen that the effect of increasing the plate potential is to shift the curves as a whole upward and toward the left in such a way that they remain almost parallel to their original position. This variation is quite regular so that it is possible to estimate accurately the position of curves corresponding to intermediate values of plate potential, and it is even possible to visualize the position of curves corresponding to higher and lower plate potentials than those given. For any given value of grid potential the plate current is greater, the greater the plate potential is.

The characteristic curves do not depend solely on the tube, but also on the circuit with which it is associated. Curves obtained with one particular circuit will be different from those obtained with any other. The

Digitized by Google

difference is usually slight, but it is important to know the effect of various changes in the connections. In Figs. A to G is shown a set of circuits which are in daily use. Another set of circuits may be obtained by putting the filament rheostat in the negative lead to the filament. All of these circuits would give slightly different curves. These curves would not differ greatly in shape, as that depends mainly on the structure of the tube and on the filament temperature, but their position with respect to the reference framework would be different; that is, they would be shifted with respect to the line of zero grid potential.

Fig. A is the same circuit as Fig. 2. Hence curves obtained with it will be the same as the curves in Fig. 1. Fig. B differs from Fig. A only in that the plate return lead, or the negative terminal of the plate battery, is connected to the negative side of the filament battery. This is equivalent to a decrease in the plate potential by an amount equal to the voltage of the filament battery. The curves will then be shifted downward and to the right by a small amount. In both of these circuits the grid return lead is connected to the negative side of the filament battery. Hence the grid will be negative with respect to every part of the filament. This is a desirable condition in amplifier circuits, and consequently these two are used for that purpose.

Figs. C and D differ from each other in the same way that A and B differ; that is, the effective plate potential of C is greater than that of D by an amount equal to the voltage of the filament battery. The two differ from the preceding circuits in that the grid return lead is connected to the positive side of the filament battery. This renders the grid positive with respect to every part of the filament. This condition is desirable in detector circuits when detecting with grid condenser and grid leak. Hence, Figs. C and D are used for that purpose.

The effect in Figs. A and B of putting the filament rheostat in the negative lead to the filament is to make the grid more negative with respect to the filament; that is, it is equivalent to inserting a small negative grid biasing battery in the grid circuit. The amount of this bias depends on the resistance in the rheostat and the current flowing through it. It may vary from a small fraction of a volt to one or two volts. This connection is desirable in amplifier circuits for certain values of plate potential. The effect in Figs. C and D of putting the rheostat in the negative lead is to make the grid more positive with respect to the filament. This may make the grid too much positive for best detection and therefore it is usually not desirable.

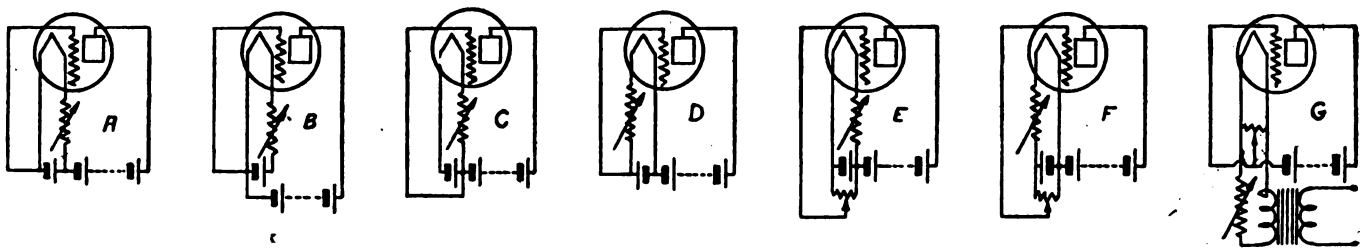
Fig. E is a type of circuit that is used quite extensively in detectors and amplifiers. It is like Fig. A in its plate connection, but unlike it in that the grid return lead is connected to the sliding contact of a high resistance potentiometer which is connected across the filament battery. This makes it possible to adjust the grid potential to have any value between the two extremes of the filament battery. This is useful in both amplifier and detector circuits as it furnishes a fine adjustment of the grid potential. This is essential in "soft" detector tubes if they are to work at their maximum detecting efficiency. Fig. F differs from Fig. E in the connection of the plate return lead. These two circuits become identical if the plate return lead is connected to the sliding contact of the potentiometer.

Fig. G shows a circuit which is so arranged that the grid may be kept at a potential half way between the two terminals of the filament, as in Figs. E and F, and in which the filament is heated with alternating current. If the grid return is connected to the middle point of the high resistance potentiometer one half of the filament is at a higher potential than the grid and the other half is at a lower. This holds for both direct and alternating current, and it holds for all instantaneous values of the alternating current. Hence the average value of the filament potential with respect to the grid is zero at all times during the alternating current cycle. This balances out the generator hum which would otherwise be present in the output of the tube. This effect is not upset when a biasing battery is inserted in the grid circuit.

All the circuits shown above are different, but their differences may be reduced to two types; namely, a difference in the effective plate potential and a difference in the normal grid potential. The effect of a change in either of these may be seen from the curves in Fig. 1. The first produces a shift of the curves so that they remain parallel to their original position, while the second merely shifts them along the axis of grid voltage.

How do the curves show what negative grid biasing battery is needed to produce best a certain desired result, say greatest amplifying efficiency or greatest detection efficiency? Referring to the lowest curve in the figure, assume first that there is no grid biasing battery in the circuit and that an alternating voltage of amplitude 10 volts is impressed on the grid circuit. Then the grid voltage will fluctuate between minus 10 and plus 10 volts. When the voltage is plus 10 the plate current is 11.25 milliamperes and when the voltage is minus 10 the plate current is 1.25 milliamperes. Hence the impressed voltage of double amplitude 20 produces a fluctuation in the plate current of double amplitude of 10 milliamperes. Now insert a 10-volt negative grid bias in the circuit. The grid voltage will now fluctuate between zero and minus 20 volts. When the grid voltage is zero the plate current is 6 milliamperes and when the grid voltage is minus 20 the plate current is zero. Hence the fluctuation in the plate current now has a double amplitude of 6 milliamperes. Now insert a grid bias of 20 volts. The grid voltage will now fluctuate between minus 10 and minus 30. When the grid is at minus 10 the plate current is 1.25 milliamperes, and when it is minus 30 the plate current is zero. In fact, there is no current at all when the grid voltage is less than minus 20 volts. That means that there will be uni-directional pulses of current corresponding to the positive half of the input wave. In other words, the tube acts as a rectifier of electric oscillations. But the greatest rectification or detecting efficiency does not

(*Concluded on page* 18)



Figs. A, B, C, D, E, F, G. Schematic diagrams of vacuum tube circuits as used in experimental work to determine which method of obtaining the grid bias functions best with various tubes for various types of circuits.

Brudenell P. Boyle, assistant manager London office of the Westinghouse Electric International Co., who is on a business trip to this country, predicts a general but slow improvement in European business conditions. He believes the general increase in confidence is reflected in the building boom in England. The building industry is the only one that is showing real signs of activity, with the steel and electrical industries following. Mr. Boyle believes there can be no real stability in Europe until the Ruhr matter is settled, and he sees no immediate prospect of a settlement.

(*Concluded from page* 15)

occur at the point where the plate current becomes zero, but at the point of greatest curvature of the characteristic. This is represented by the intersections of the line AB with the curves, which for the curve in question is at minus 10 volts. Hence this is the negative grid bias required when the tube is operated as a detector-rectifier or a modulator.

If the tube is to be operated as amplifier and greatest possible amplification is desired, it must be operated at the point of the curve where the slope is steepest, because here a given variation in the grid potential will produce the greatest fluctuation in the plate current. This point is approximately shown by the intersection of the line CD with the curves. This is the point of inflection, where the curve changes its curvature from rising to falling, and is therefore the steepest possible part. For the lowest curve this point coincides with the line of zero grid potential, and therefore no grid bias is needed. For the next curve the required bias is about 4 volts, for the next about 8, and for the highest curve about 11 volts. Above the line EF the tube is of little use as an amplifier.

If the object of the tube is to secure amplification without distortion, it must be operated over a portion of the curve which is as straight as possible. Distortion is due to the curvature. Fortunately the curve is straightest where the amplification efficiency is greatest, that is, at the point of inflection, given by the intersection of the line CD. The curve is nearly a straight line in the immediate vicinity of this point If the input voltage is small, say less than a volt, there will be very little distortion, but if it is of the order of 10 volts the distortion will be serious. The peaks of the plate current fluctuations will be flattened. This will introduce harmonics and the quality of the audio output will be bad. The tube is overloaded. To improve the quality in this case the plate potential may be increased, or the filament temperature may be raised. If this is not sufficient it will be necessary to use a power tube. In radio frequency amplification, distortion is not of much importance and therefore the tube may be operated at a point where the amplification efficiency is far below maximum. This is usually done to prevent oscillations. If the tube is working duplex, however, this is not allowable, as distortion would be introduced into the audio component. But high frequency oscillations may then be prevented by inserting a resistance of suitable value into the circuit being used.

It is not supposed that all experimenters and users of vacuum tubes have access to characteristic curves of their tubes, nor is it expected that they purchase the necessary meters with which to obtain their own curves. But this does not detract from the qualitative value of these curves. If the experimenter fixes firmly in his mind the general shape of some typical curves, together with the effect upon these curves of making various changes in the connections, the grid and plate potentials, and the filament temperature, he may more quickly reach the desired results experimentally by acting in accordance with his mental picture of the curves. The various changes that he makes need not be hit-or miss, but will have a definite purpose behind them.

"B" Battery Control and Improvement

By C. White, Consulting Engineer

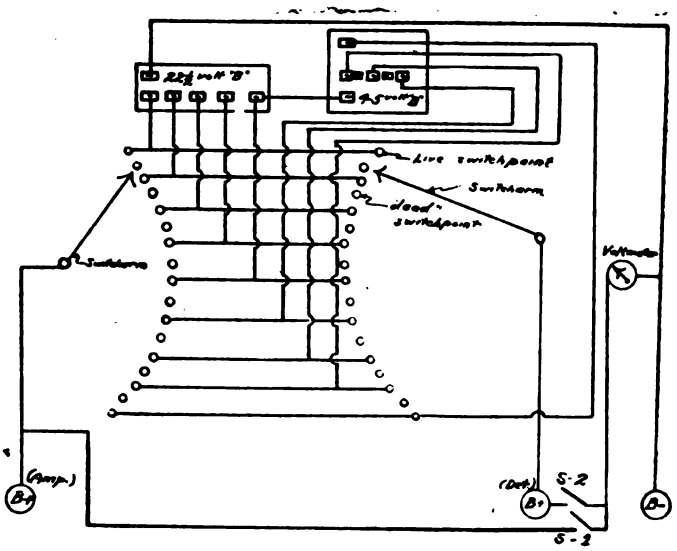
TO many amateurs the taps on the "B" battery have little or no practical use. They are often set at a given point and there the wire stays attached until something goes wrong. Generally a decrease in volume leads to an investigation of the "B" batteries. Then there is the amateur who has burnt out one or more tubes while adjusting the taps on his "B" battery and now he has the motto "hands off" as long as things move in some manner. It must be admitted that with the average set the "B" batteries are placed in a rather inconvenient place and the mass of wires behind the set leads to confusion that might result in tube casualties. The ideal arrangement for this very necessary control is the type of "B" box as outlined in this article. This box not only affords a rapid and safe method of shifting plate voltage on the detector and the amplifier but also a very quick and reliable test of the batteries. It will be well worth the time and the money to construct this outfit.

I have shown in the illustration the "B" box hooked-up to two blocks of batteries, one a 22½ and the other a 45, but you are not in the least confined to this arrangement of voltage taps; in fact, you can arrange the actual connections to the "B" batteries as best suits your particular set. If you so desire you can get a cabinet that is big enough to hold the "B" batteries or you can place the batteries outside the box. The number of taps is, of course, optional, but it is recommended that a "dead" switchpoint be placed between each two "live" ones. This is done to prevent the possibility of short-circuiting a particular cell of the "B" battery by resting the switch arm between two live contacts instead of on one only. This is impossible to do when a dead point is interposed even when shifting the switch arm. The two switches marked S-1 and S-2 are push buttons of the door bell type. It is easy to purchase these buttons in the countersunk pearl style which makes a very neat appearance for a panel-mounting. A voltmeter is one of the required articles for the "B" box. If you have not one in your possession at present I would advise you to invest in one as soon as you can. A good radio fan must be able to check up his "B" as well as his "A" battery conditions at all times.

A depleted plate battery will not only cause a diminution in volume but also introduces a certain grade of home-made static. A reliable voltmeter is the only method to tell whether your batteries in the plate circuit are still functioning properly. It is generally conceded by the dry cell "B" battery manufacturers that that type of battery is of little use when the voltage on the 22½ volt size falls below 17, and serious noise is often introduced when the 45 volt size goes below 34. This rule is by no means exact for I have personally used on amplifiers 22½ volt batteries that measured about 10 volts and got quiet operation, but this is too exceptional to be called a general occurrence, although many amateurs are getting remarkably long service from their plate batteries.

For testing a dry cell "A" battery an ammeter reading at least 35 amperes will be required. A new "A" battery will read anywhere from 27 to 35 amperes on short circuit by the ammeter. Of course, such a test should be made rather hastily, but if your battery only goes up to 10 or 12 amperes on the initial jump and falls very rapidly the cell is beginning to reach the discarding stage. A storage "A" battery should never be tested with an ammeter or voltmeter; the former would most likely be burnt out and the latter would indicate nothing of value as to the amount of charge in the battery. The hydrometer is the most simple and reliable way to test a storage "A."

Now as to the problem of bringing out the leads in the proper order so as to make the operation of connecting them to the "B" batteries as simple and safe as possible. One method is to tag each wire separately, but as you can easily see this would mean a lot of tags hanging around to be lost or torn off, and besides it would not make a neat job. The best method of bringing out the leads that are to be connected on to the



Arrangement for the amateur who is fussy about the way in which his set functions and likes to have his plate batteries arranged so that different plate potentials may be used. Also an arrangement whereby the condition of each cell, or group of cells, may be tested by means of the voltmeter to determine their condition.

battery taps is by the use of the so-called coded wire. Coded wire is wire that is covered with insulation that is so colored and striped as to be readily identified; in other words the 18 volt tap wire could be black with a solid red stripe, while the 19½ volt tap connection could be black with a dotted yellow stripe. There are many combinations of colors and stripes, so you will experience little difficulty in getting any desired number of groups. The end negative wire should have one solid color, generally coded blue or black, while the last positive tap should be red. It is obvious with such a coding system made up and listed you can easily change your "B" batteries without going all over the wires each time. This coded wire can be purchased from any electrical store or telephone supply house; if not procurable at the former you will be sure of getting it at the latter since it is extensively employed in telephone wiring.

The "B" box will not fail to give your tubes the proper amount of plate voltage and will afford an instant check on the condition of the batteries. By closing S-1 you can ascertain the exact voltage on the plates of the amplifiers and by closing S-2 the same can be found out for the detector. Never close S-1 and S-2 at the same time because this action would short circuit part of the battery. While the "B" box has been used on some deluxe cabinet and console models, it has not been generally used by amateur builders.

Answers to Readers of Radio World

Have constructed the circuit described by A. S. Gordon in RADIO WORLD, *April* 14, *page* 4. *How can I add additional amplification to this circuit?—Roy Maguire,* 899 *Neptune Ave., Coney Island, N. Y.*

If you will refer to the Answers to Readers column of RADIO WORLD, August 18, you will find the diagram you wish. This will enable you to add another two-stage unit to your set.

* * *

I desire to study the code and the theory of radio, to enable me to enter the radio branch of the navy. Can you advise me just what course I should pursue?—Jack Laitin, Minneapolis, Minn.

The navy trains men for this service. Put in an application with the commandant of the nearest navy yard, and he will inform you of the location of the nearest radio school of the navy.

* * *

I have the standard three-circuit regenerative receiver. I want to use this circuit with a loop antenna and not use any radio-frequency. The circuit uses detector and two stages of audio-frequency. Could I convert this into a super-regenerator? Would a super give me greater volume than the one that I have now? What wave length will the receiver respond to?—Harry Kenaga, El Reno, Okla.

You cannot operate your present set on a loop. In order to use a loop you must use radio-frequency or a super-regenerative circuit such as is herewith given. The parts are all marked. The loop you mention is O. K. for use with this circuit. The circuit will cover all the broadcasting wave lengths. You cannot use dry cell tubes with this circuit and do it justice. The best tubes for use with this circuit are the 216A or five watt tubes due to the plate voltage used.

* * *

Will you publish a diagram of a one tube super-regenerative hook-up using either an outdoor antenna or a loop?—J. Shultz, 3409 *Beniteau, Detroit, Mich.*

We refer you to page 9 of RADIO WORLD, March 17, 1923, where you will find the article you desire, written by W. S. Thompson.

* * *

Where could I obtain a circuit diagram which would enable me to add two stages of audio-frequency amplification to the circuit described in RADIO WORLD, *April* 14, *by A. Gordon? What size wire should be employed in hooking up the set? I notice that when I place my finger on the grid post of the grid condenser that the signals come in louder. Why is this?—J. Kaiser,* 2208 *Neptune Avenue, Coney Island, N. Y.*

You will find the hook-up you want in RADIO WORLD August 18, in the answers to readers department. Use No. 14 tinned bus wire, covering it with spaghetti. Change your grid condenser for one of larger size—the one you have now is too small for your tube.

* * *

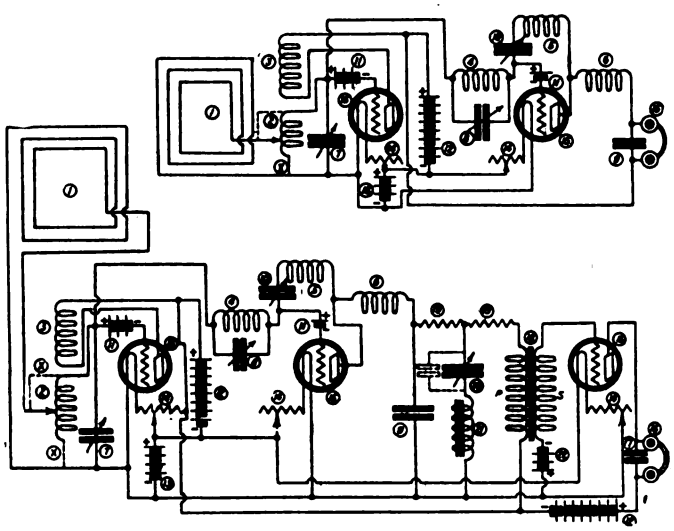
Does it matter if when using phones in a receiver, one pair is 2000 *ohms and the other is a single* 1000 *ohm receiver? I have been told that it cuts my volume down.—Jack Scheweiss, New York City.*

This should not make any appreciable difference, if the phones are of good make and in good condition.

* * *

I have had a power amplifier for nine months. It has at times a tendency to be "muffled." I have been told that the "C" battery needs replacement. Can this be the possible reason?—Philip Domidon, Brooklyn, N. Y.

It is possible that this is the cause of your trouble, although these batteries should last for more than nine months. Renew it, anyway, being careful that you reconnect the new one in the exact manner as the old one.



A diagrammatic hook-up of two and three stage super-regenerative receivers. The constants of the circuit, according to the numerals on the diagrams, are as follows: 1—Loop antenna. 2—Primary of variocoupler, (55 turns). 3—Secondary of coupler (wound with 90 turns of No. 30 wire). 4—Duolateral honeycomb 1250 or equivalent. 5—Small air choke coil of 9 millihenries inductance. (A 250 honeycomb will do.) 6—Duolateral honeycomb 1500 or equivalent. 7—.001 mfd variable condenser. 8—.0025 variable condenser. 9—.005 fixed condenser. 10—.001 variable condenser. 11—Grid battery. 12—B battery (90-120 volts). 13—A battery. 14—Rheostats. 15—Tubes (hard). 16—Telephones. 17—.0005 fixed condenser. 18—Audio frequency amplifying transformer. 19—12,000 ohm resistance filter. 20—Capacity determined by experiment should be between .002 and .005 mfd. 21—Choke coil—100 millihenries. 22—Grid bias battery (3-12 volts). The constants are the same for both circuits, and should be adhered to. Diagrams by permission of S. Newman.

*Please inform me what transformers are to be used in W. S. Thompson's reflex Grimes circuit. I have read in articles that the UV*199 *tubes do not work well with transformer coupled radio-frequency circuits. Is this so? If so, why do they sell them for that purpose?—G. O. Halvig, Lock Box* 252, *Dawson, Minn.*

We cannot recommend through this department any particular make of competitive apparatus. Buy the best you can. This applies to all apparatus bought. The best is the cheapest in the end. The tubes mentioned work with transformers if all the directions are carried out.

* * *

Can I use an insulated wire for my antenna? Is it necessary to use more than a single wire for receiving? What kind of wire should be used?—Ethelbert Huber, 2062 *Broadway, New York City.*

You may use insulated wire for antenna, as the ether waves find no diffculty in passing through the insulation. However, no advantage would be gained by the use of the wire, and the extra expense involved is not warranted. A single wire is all that is necessary for receiving. You may use copper, aluminum, copper-clad wire, phosphor bronze, or in a pinch, even iron wire will do. The important thing, is the complete insulation of the erected wire, to prevent its grounding. Aluminum is not used much now, because of its lack of tensile strength and its tendency to quickly corrode and render any joint except an aluminum soldered joint, a high resistance.

* * *

What is tuned radio-frequency amplification used for? Can I use it in a set with a loose coupler and a crystal detector? Will it help my receiver?—Joe K. Lee, Atlanta, Ga.

Tuned radio-frequency amplification is used for increasing the range of a receiver, by amplifying the minute impulses before they are rectified and therefore making signals that would be too weak to actuate the phones or amplifiers audible. In tuned (impedance) radio-frequency amplification, advantage is taken of tuning the amplifiers to the incoming wave and obtaining additional efficiency. You may use it with a crystal detector if you wish. It will help your receiver, to cover greater distances. See RADIO WORLD, July 14, for circuit diagrams and explanations.

* * *

*Can radio-frequency amplification be added to the Westinghouse Radiola, Sr., using UV*199 *tubes? Is the new Grimes inverse better than the improved Grimes reflex as outlined by Thompson? Can a tube be used as a detector in place of the crystal? Is there any advantage to be gained by using crystal detectors in reflex circuits?—N. A. Reinhard,* 548 *Arnett Blvd., Rochester, N. Y.*

Radio-frequency cannot be added to the Senior very well without rebuilding the set, which would not be worth the trouble. The set is not designed for radio-frequency, and should not be used with it. The Grimes you mention (Thompson) is the regular Grimes inverse duplex, with the addition of a stage of pure radio-frequency ahead of the reflexed tubes. It is not advisable to use a tube as a detector in this circuit. The advantage of the crystal is absolutely faithful reproduction of the signals and speech. The added volume gained by the use of a tube is so small that it really does not warrant the loss of clearness and tone by the use of the tube.

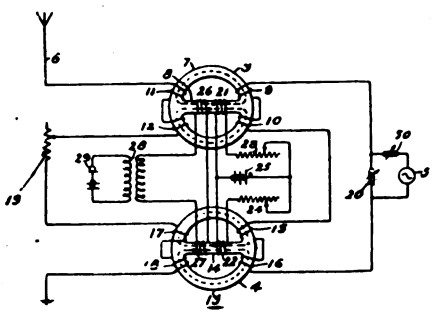
Latest Radio Patents

Modulating System

No. 1,462,838: Patented July 17, 1923. Patentee: R. V. L. Hartley, South Orange, N. J.

The invention relates to modulating systems, or systems for supplying a high frequency wave which varies in amplitude in accordance with the wave form of a signal to be transmitted.

It is well known that a wave of the high frequency *f*, modulated in accordance with the signal frequency *a*, where *a* is the instantaneous value of the signal frequency, may be considered as composed of three components having the frequencies *f*, *f*+*a* and *f*—*a*. Considerable power is wasted in radiating the unmodulated component of frequency *f*, and it is desirable for efficient transmission to radiate only the pure modulated waves of freuencies *f*+*a* and *f*—*a*, the unmodulated component being restored in any suitable manner at the receiving station.



New method of telephone modulation.

An object of the present invention is to provide a modulating system for transmitting a pure modulated wave.

The invention makes use of reactance modulators of the transformer type for controlling the high frequency output by varying the mutual inductance beween the primary and secondary winding of the transformer in accordance with a signal to be transmitted. The amplitude of the high frequency currents radiated depends upon the coupling between the primary and secondary windings and by varying this coupling, i. e., the mutual inductance, in accordance with the signal, a modulation of the carrier wave is effected. The variation in coupling is effected by varying the permeabilities of the transformer cores in accordance with the signal currents. The secondary windings of the two transformers are connected to the antenna in opposition to each other, so that no high frequency power is radiated in the absence of signaling currents. The effect of signaling currents is to increase the permeability of one transformer core, and to decrease the permeability of the other transformer core. This disturbs the balance of the opposed secondary windings, and modulated high frequency power is radiated.

The modulated wave supplied by one of the secondary windings has the three components with frequencies *f*, *f*+*a* and *f*—*a*, and the opposing modulated wave supplied by the secondary winding of the other transformer has three similar components, with the same frequencies. The two opposed unmodulated components of frequency *f* are not varied in amplitude by the signal current of frequency *a*, and these components are always balanced out so that no unmodulated power is transmitted. The pure modulated waves of frequencies *f*+*a* and *f*—*a*, developed in the transformers by the signal currents, agree in phase and so reinforce each other.

Another object of the invention is to prevent the induction of radio frequency currents in the excitation winding. This is accomplished by providing two paths in opposition for the high frequency flux, the excitation winding being linked by both fluxes so that the effect of the opposed fluxes is to induce no resultant E. M. F. in the excitation winding.

A source of steady current is used to bring the permeability of the cores to the desired point about which the permeability is changed by the signaling currents.

A further object of the invention is to use a single excitation winding for each transformer, which is to be supplied by both the steady source and the signaling source, the currents from these sources aiding in one winding and opposing in the other, and to prevent the currents supplied by each source from being short-circuited through the other source. To this end the invention provides an impedance coil circuit with the steady source and a condenser in circuit with the signaling source. The steady current cannot traverse the condenser, while the variable signaling currents cannot pass through the impedance coil, so that both currents are properly supplied to the single excitation winding.

It has been determined that best results are obtained when the modulators are energized by a generator which acts as a pure resistance. In order to provide such a generator the reactance of the same is neutralized by a reactance of opposite characteristics. For instance, if the generator has inductance, then a capacity is provided to neutralize the inductance of the generator which accordingly acts as a pure resistance.

Radiotelegraph System

No. 1,463,391: Patented July 31, 1923. Patentees: E. C. Hanson and W. C. Carlson, Washington, D. C.

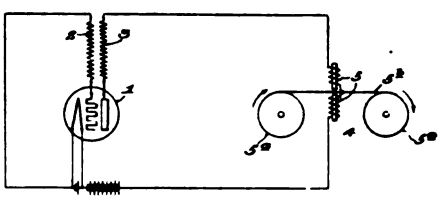
Our invention relates to the reception of wireless signals and more particularly to those systems operating on the undamped wave principle.

Heretofore, in order to actuate a signal responsive device it has been generally necessary to convert the received radio frequency energy directly into an audible frequency.

The object of our invention is to provide an arrangement for receiving undamped radio wave signals without first converting the radio frequency energy into an audible frequency.

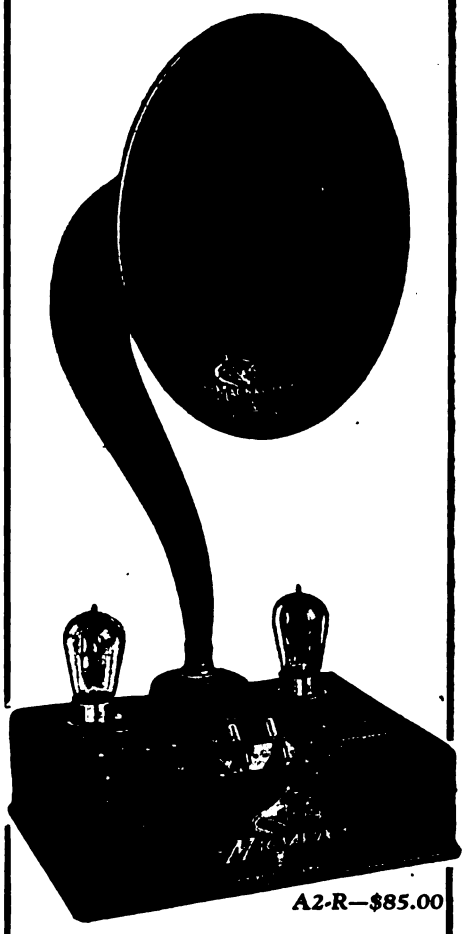
Another object of this invention is to provide an electric circuit for first recording radio signals and subsequently reproducing the recorded signals.

A further object of the present invention is to provide a circuit which will respond efficiently to sustained radio frequencies, but which will not respond efficiently to audio frequencies and strays.



Method of recording telegraphic signals.

MAGNAVOX
Radio Products



A2-R—$85.00

MAGNAVOX Radio Combination Set A2-R consists of electro-dynamic reproducer and 2-stage Power Amplifier, as illustrated. This instrument insures the utmost in convenient, perfect reproduction with any good receiving set.

Magnavox Reproducers

R2 with 18-inch curvex horn $60.00
R3 with 14-inch curvex horn $35.00
M1 with 14-in. curvex horn. Requires no battey for the field . $35.00

Magnavox Combination Sets

A1-R consisting of electro-dynamic Reproducer with 14-inch curvex horn and 1 stage of amplification $59.00
A2-R consisting of electro-dynamic Reproducer with 14-inch curvex horn and 2 stages of amplification $85.00

Magnavox Power Amplifiers

A1—new 1-stage Power Amplifier $27.50
AC-2-C—2-stage Power Amplifier $55.00
AC-3-C—3-stage Power Amplifier $75.00

Magnavox products can be had at Registered Magnavox Dealers everywhere. Write for new 32-page catalogue.

Everybody Should Boost National Radio Week

ARE you doing your share towards boosting National Radio Week which runs from November 25 to December 1, 1923?

Everybody interested in the art, science and business of radio should do everything possible to make the second annual National Radio Week bigger, better and more important in every way than the first annual event of last year.

If you have any original ideas send them to RADIO WORLD and we shall be glad to pass them on for discussion and action.

Radio Show Features to Interest Public

ONE of the interesting features provided for the second annual Radio Show, at Grand Central Palace, New York City, from October 6 to October 13, will be a series of motion pictures illustrating the practical uses of radio and the principles of operation.

Open to amateurs under 18 years of age, living within 100 miles of New York City, will be a set construction competition which doubtless will attract many.

It is expected that a radio dance will be held frequently, perhaps every night, the music being received from one of the broadcasting stations.

The principal radio reception set at the show will be in charge of the Radio Club of America, who also are the constructors of the set.

The following organizations have reserved exhibition space:

Crosley Mfg. Company, Radio Corporation of America, Western Electric Company, C. Brandes, Inc., Cutler-Hammer Co., Cutting & Washington Co., DeForest Radio Tel. & Tel. Co., Dubilier Condenser Co., Electric Storage Battery Co., Fiber Products Co., Gimbel Brothers, Gould Storage Battery Co., Grebe & Company, Inc., C. B. Kennedy & Co., Manufacturers Patent Co., Multiple Electric Products, Marko Storage Battery Co., National Carbon Co., Post Electric Co., Precision Equipment Co., Radio Digest, Radio Industries, Rocky Mountain Co., Weston Electric Instrument Co., Moon Radio Co., Neon Lamp Works, R. Mitchell & Co., Nathaniel Baldwin, Pathe Radio Co., Rasla Sales Co., Malone-Lemmon Laboratory, Eisemann Magneto Corp., Gilfillan Brothers, Willard Storage Battery, National Radio Products, Sleeper Radio Co., Horne Electric Mfg. Co., Allen D. Cardwell & Co., Sec-Tron Radio Co., Lefax, Inc., Holtzer-Cabot Company, Graham & Company, Bristol Company, Radio Dealer, J. D. Timmons & Co., New York Evening Journal, Experimenter Publishing Co., American Radio Research Corp., Acme Apparatus Company, American Radio Relay League, American Radio Journal, L. & W. Spring Co., National Airphone Co., Alden Mfg. Co., Burgess Battery Co., Pacent Electric Co., Magnavox Co., Automatic Electrical Devices Co., Federal Radio Co., Radio Publishing Co., Adams-Morgan Co., Engravers & Printers Machinery Co., Atwater-Kent Co.

Radio Sales to Farmers Should Result from Good Harvest

THAT the farmers of the United States are this year the biggest bunch of prospects in sight for the radio industry is being demonstrated almost every day. An editorial in the New York "World" is evidence of this fact. It reads in part as follows:

"The season's crops are virtually made as they appear in the Sept. 1 report on condition of the Department of Agriculture. Spring wheat suffered some little decline in estimated yield from a month ago, but the total wheat harvest is within 29,000,000 bushels of the 818,000,000 bushels produced last year. Corn will be a larger crop than then. So of oats, barley and tobacco. White potatoes at 390,000,000 bushels are a good average if 48,000,000 bushels below last year's yield. It is a year of plenty. Only rarely in this respect has the country been more greatly favored."

Radio Code to Japan Barred

THE Japanese Government has forbidden the use of code in radio as well as cable messages sent to Japan during the present emergency. The Radio Corporation of America was notified that on orders from Tokio no messages would be received at the Japanese Government radio station at Iwaki, Japan, which were written in any language other than plain English or Japanese.

Radio Literature Wanted

Manufacturers of and dealers in radio apparatus and accessories are notified that literature and catalogues describing their products have been requested, through the Service Editor of RADIO WORLD, by the following:

Clarence Thompson, 53 Appleton City, Missouri.
C. R. Crawford, 1006 Pender Street West, Vancouver, B. C., Canada.
L. F. Hewlett, 8713 Colonial Road, Brooklyn, N. Y.
Maybrook Radio Supply, Maybrook, N. Y. (Dealer.)
Latto Radio Service, 1937 Reid Avenue, Lorain, Ohio.
Chester Wilson, 3306 Freeman Avenue, Kansas City, Kansas.
Chas. F. Bomer, 8703 139th Street, Jamaica, N. Y.
J. S. Hagans, Box 447, Chicago, Ill.
Beardslee Radio Laboratory, 125 Scott Street, Wheaton, Ill. (Retailers.)
F. W. Kerchner, M. D., Glen Carbon, Ill.
J. D. Oakes, Flotonia, Texas.
Ray O. Townsend, Box 91, Cape Charles, Va.
H. V. Montgomery, 1715 Glendale Avenue, Detroit, Mich.
Elmer E. Martin, North Lima, Ohio.
C. A. Robinson, 917 Seventh Street, Charleston, W. Va.
John H. Allen, 1002 West Street, Wilmington, Del.
Robert S. Cook, 1426 Asbury Avenue, Evanston, Ill.
B. Weiss, 96 Watkins Street, Brooklyn, N. Y.
Wm. E. Thompson, R No. 1, Box 34, Barron, Wisconsin.
J. F. Totten, Jr., 830 Stanbridge Street, Norristown, Pa.
Robert H. Walters, R. 1, Box 40, Glidden, Iowa.
Frank Maguire, 130 Hamilton St., Cambridge, Mass.
D. J. Elliott, 161 Penna. Ave., Wilson, Pa.

Radio Trade Notes

A discharge in bankruptcy has been granted to Beatrice K. Owen, who was a partner in the Beacon Radio & Electric Co., at 246 Greenwich Street, New York City.

* * *

A petition in bankruptcy has been filed against the Electrical Corporation of America, manufacturer of radio parts, 428 Broadway, New York City, by August Heusel for $275, Holmes & Rice $338, Whitman Advertisers' Service, Inc., $192. Richard Campbell was appointed receiver under $5,000 bond by Judge Manton. Liabilities about $36,000; assets about $20,000.

* * *

Bankruptcy proceedings have been instituted against the Witherbee Storage Battery Co., Inc., 234 West 55th Street, New York City, by Eagle-Pitcher Lead Co., for $1,500, Broadway Tire Jobbers, Inc., $100, Graselli Chemical Co. $800, Dorothy Spero $18.

* * *

Elmer E. Martin, North Lima, Ohio, plans to sell sets and parts to the rural population in his vicinity.

* * *

The Fullerton Electric Co., 230 West Seventeenth street, New York City, has had confirmed a composition with its creditors on a 50 per cent. basis.

* * *

Wm. C. Shackett has obtained a judgment for $173.39 against the Continental Radio & Electric Corporation of New York City.

Andrea Welcomes Patent Suit by Radio Corporation of America

UNDER the caption "Keeping in Style" F. A. D. Andrea, Inc., 1581 Jerome Ave., New York City, sends the following communication to RADIO WORLD:

"Early this year our friend and worthy competitor, A. H. Grebe & Co., announced 'A New Spring Suit,' bearing reference to litigation instigated by the Radio Corporation of America.

"We take pleasure in advising the trade that within the past few days 'A New Fall Suit' has been filed by the Radio Corporation of America against F. A. D. Andrea, Inc., the substance of which is alleged infringement of the Rice & Hartley patents Nos. 1334118 and 1183875, respectively, through the manufacture and sale of radio receivers embodying the Hazeltine Neutrodyne circuit, in accordance with the patents and pending applications of Hazeltine.

"This action is most welcome as it affords opportunity for early adjudication of the validity and scope of the Rice & Hartley patents and the alleged infringement of these patents by apparatus manufactured and sold under the Hazeltine patents and pending application.

"This 'New Fall Suit' will be defended by F. A. D. Andrea, Inc., with the cooperation and support of the Independent Radio Manufacturers, Inc., of which organization F. A. D. Andrea, Inc., is a member.

"The Independent Radio Manufacturers, Inc., is a group of radio manufacturing companies who are prominent factors in the radio industry and whose interests are pooled as regards the use of certain patented inventions and the prosecution and defense thereof.

"The trade will no doubt recall the work of this organization last year in connection with the crystal patent litigation, instituted by the Radio Corporation's associate, the Wireless Specialty Apparatus Company, and the commendable action taken by the organization, both as regards the defense and the prosecution of its rights in this situation.

"The Independent Radio Manufacturers, Inc., are represented in patent matters by the firm of Penny, Davis, Marvin & Edmonds. They advise that there is a good and valid defense to the suit started by the Radio Corporation of America on the Rice & Hartley patents.

"From our legal advice we are lead to the independent and firm belief that the defense of our 'New Fall Suit' will result in absolutely no change in our activities in connection with the Hazeltine Neutrodyne receivers, and therefore both at present and in the future the manufacture and sale of this receiver will continue unabated.

Very truly yours,
F. A. D. ANDREA, INC.

Kansas Telephone Company Gives Radio Broadcast

THERE are ever and anon new ideas popping up in some quarter or other, be it radio or telephone or the pruning of hedges. The latest radio wrinkle that has proved to be of a real service was tried out by J. A. Gustafson, manager of the Fredonia Telephone Co., Fredonia, Kansas.

Being a radio enthusiast he thought he could make the telephones serve some other purpose than the regular line work. He therefore hooked up a power amplifier to the regular lines, and informed the subscribers that for the nominal sum of one dollar a month he would furnish them with radio programs over the telephone. He does not furnish loud speakers, but he furnishes the programs, which he picks up "in the air" and relays over the land lines. The programs start early in the morning with the market and crop reports and continue all day long, time signals, and dance music being given. A lot depends upon Mr. Gustafson's ability to satisfy the multitude, so he must pick out the programs that he thinks will please the entire list.

It might be of interest to state that there are 75 installations made to date, and that none of them interferes with the regulation traffic of ordinary everyday telephoning.

Compact Loop Antenna

A NEW form of loop antenna, or more properly compact folding loop antenna, has been devised by the Rocky Mountain Radio Company, 9 Church street, New York City. Instead of using many consecutive turns of wire this new antenna consists of a spiral spring which is really 80 feet long, but due to its construction, the loop itself is simply one turn of this spring.

The loop can be erected or taken down in 30 seconds, due to its peculiar construction, and when folded, occupies an exceedingly small space. The present construction as regards the spiral wire has been tested and found to equal any of the other form of loops of the solenoid variety, which take up quite a bit of space even when made in the portable form.

Radio Birthday Party

VAUGHN DE LEATH has extended a special invitation to all Station WDT fans to listen in to a special birthday program which will be broadcast from that station on September 26th.

There are many novelties and exceptionally fine numbers to be provided for the occasion.

The hour is an early one—seven to eight p. m. In fact, Vaughn says she does not think many people know about that early hour on Wednesday night. But she hopes everyone will be listening in on September 26th to attend her birthday party.

Radio Canoeists on Portage Lakes Hear Fight Returns

AKRON, Ohio.—Radio equipped canoes have become an essential part of the duffle of the modern camper, according to two local amateurs, who, while experimenting with a portable set on the Portage Lakes, heard fight returns from Eastern broadcast stations and amateur transmitters as far away as Philadelphia and Chicago. D. A. Hoffman, of the American Radio League and operator of the amateur station 8UX, and Fred Ash agree that radio installation on canoes is entirely practical.

A compact home-made single regenerative receiver, using a detector and one stage audio amplification with C299 tubes, was available. This set, with a motorcycle storage battery and the necessary B batteries, was placed on the bottom of the canoe. Two six-foot bamboo poles were stuck in the flag sockets at each end and a spiral aerial, consisting of 150 feet of insulated fixture wire, was looped between the two poles on a piece of clothesline.

The ground consisted of a ten-foot piece of bare wire which was connected to the set at one end and dropped overboard.

Each of the two experimenters wore a headset and the first station copied was 9AJA, Chicago. Other amateurs heard were 9EKU, Devil's Lake, North Dakota; 9EKF, St. Louis, Mo.; 8DGX, Pittsburgh, Pa.; 8OK, Lewisburg, W. Va.; 8SF, Sharpsburgh, Pa., and 9AWK, Elgin, Ill. All but two of these were CW stations and came in with good intensity.

Fight returns from KDKA and concerts from WLW were also heard plainly. Other canoeists who witnessed the experiments were envious. Hoffman says he will make other experiments with a transmitter in an effort to establish two-way communication with amateur stations within 100 miles of his canoe. The stunt of transmitting from such a small craft presents a big problem, but it is just such problems that the amateur fraternity are always eager to solve.

Station WBZ Broadcasts City Chimes

ONE of the new features on WBZ's interesting and varied program is the broadcasting of the chimes located in the lofty "Campanile," the Madison Square Tower of Springfield, Mass. These chimes, which can be heard for miles round the country, are broadcast every Sunday night before church services at 7:30 p. m.

The selections open with the playing of "America," and end with "Taps." Because of their great beauty and variety, it is possible to play many fine musical numbers and selections. Several tests have demonstrated the beauty of music from chimes, which is particularly adapted to radio broadcasting.

It is an interesting and unusual fact that listeners at their radio receiving sets located thousands of miles away receive the music from the chimes several seconds before the strollers in the municipal park near the Campanile or by the men in the fields about the city. It takes actually less time for the electric impulses carrying the music to make the journey over the wires to the Westinghouse broadcasting plant in East Springfield, and to send them broadcast for thousands of miles, than it does for the sound waves themselves to reach the ears of the listeners in the park, several hundred feet below. In fact, the radio waves could circle the earth seven times before the sound could go 1,000 feet.

This is due to the fact that sound waves travel much slower than radio waves, which cover a thousand miles in one one-hundred-and-sixty-sixth of a second.

Proposed Broadcasting in Southern France

AN attempt is being made by local business men in Marseilles, France, to establish a broadcasting station in collaboration with the newspapers of the city. A local dealer in French-made sets is said to be the prime mover in the project.

IMPORTANT NOTICE

While every possible care is taken to state correctly matters of fact and opinion in technical and general writings covering the radio field, and every line printed is gone over with a scrupulous regard for the facts, the publisher disclaims any responsibility for statements regarding questions of patents, priority of claims, the proper working out of technical problems, or other matters that may be printed in good faith and on information furnished by those supposed to be trustworthy. This statement is made in good faith and to save time and controversy in matters over which the publisher cannot possibly have control.

Life Would Be Brighter If

THE ham next door would learn to stay in one place all evening instead of running around footloose with his single circuit squeaker and ruining all your programs with a Wheeeeeeeeeeee-squack—Wheeeeeeeeeeee, every time you think that you are going to have a second's peace.

Static wasn't sure to ruin all chances of distance just the night you bring your friends from the office up to hear "some real DX on the loud speaker."

You could tap your blown out tubes the same as you do the electric lights and make the filament last "just a few weeks more."

Every time you had your receiver finished and working some friend wouldn't pop in and tell you about "the wonderful results I got last night on the Doo Diddle Dumdum circuit" and make you unhappy that you can't do the same.

Every time you got in trouble when making a set you had the expert advice of the inventor—and the inventor himself right at your elbow.

You could get the average salesman in the average radio store to give you his real opinion of the apparatus he is trying so hard to sell to you at a bargain price.

You could make a set using a crystal that would actually bring in the broadcasters over a radius of 1,000 miles every night.

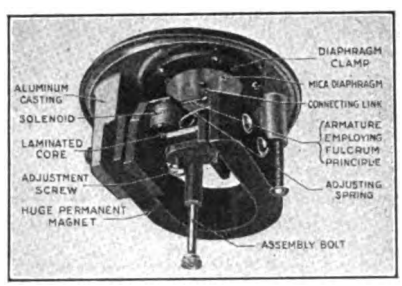
THE TRINITY LOUD SPEAKER

TYPE "A1"
21" FIBER HORN
$25.00

TYPE "B"
(For Phonographs)
$12.50



INTERIOR CONSTRUCTION

An ear phone is an ear phone no matter how fancy the horn that covers it may be, and, due to the delicate construction of an ear phone it is utterly incapable of giving true tone reproduction, especially, when relatively large currents are passed thru its coils, such as the output of a two-stage or power amplifier.

The Trinity Loud Speaker element embodies the well-proven and tested principles of the phonograph reproducer with the soundest principles of electromagnetic design best adapted for loud speaker operation. It is not an ear phone when placed on a head band and a loud speaker when covered with a horn. It is a sturdy loud-speaking element ALWAYS.

Send for Literature.

Why Tubes Sometimes Blow

JOHNNIE JONES tells the fellows down at the office that he has just put in the new radio set and invites them all up to hear the fight. Of course, they acquiesce and he sets a date for them telling friend wife that she had better prepare a few sandwiches.

That night they all gather around the radio set, which is going fine and dandy, and the stations are just coming in great. Suddenly Station BUNK opens up, and the announcer speaks something like this: "Good evening, ladies and gentlemen of our unseen audience. Before going on with the program we have an important announcement to make. Just stand by for a few seconds, please."

Every one holds his breath in expectant excitement and not a few offer suggestions of what the forthcoming announcement will be. "———er. Kauff— kauf—. This is Station BUNK. Due to the fact that unforeseen difficulties have arisen, we will not broadcast the Bennard-Battling Murphy fight tonight. In place of this we have arranged a program of very excellent talks on 'The Importance of Proteins in Your Daily Diet,' to be given by Professor Fulla Josh. I take great pleasure in introducing Professor Josh."

Now isn't that enough to make any tube just fold up and commit hari-kari?

THE COLUMBIA PRINT
1493 BROADWAY NEW YORK CITY

Mr. Shaw Believes in Long Aerials

EDITOR, RADIO WORLD:

Referring to my letter in your number of September 8th, I regret extremely to have to ask you to correct two errors.

I stated that I could not get broadcast stations with my four-tube crystal detector reflex receiving on my single wire antenna, 250 feet long (50 feet high). This was due to B battery trouble. I am now getting as good reception of broadcast stations as could be asked for on the above antenna on a three-tube regenerative circuit, a six-tube radio-frequency circuit, and a four-tube and crystal detector reflex circuit and a five-tube neutrodyne circuit.

I might add that this is my first experience with the neutrodyne circuit and I find it wonderfully satisfactory. It tunes very sharply and is the most powerful of all my circuits above mentioned.

The other mistake was to put a period in the wrong place, making it appear that I could get the shortest amateur stations better on a short 100-foot single antenna (30 feet high) than on the 250-foot antenna at Seal Harbor, Maine, which antenna is also 30 feet high. As a matter of fact and greatly to my surprise, I got 200 meters and below very much better on the 250-foot single wire antenna than on the 100-foot antenna.

My experience would lead me in putting up a new antenna to make it as high and as long as conditions would permit and if more convenient to use plain copper wire rather than multiple strand, I would not hesitate to do so. As far as I can see the reception on one is as good as on the other.

In conclusion, I would repeat—make your antenna as long as you can and as high as you can. Yours very truly,

160 State Street, W. K. SHAW.
Boston, Mass.

He Enjoys Radio, Anyway

JONESY: "Say, Bill, what do you enjoy most on your radio?"

Bill: "Well, when the wife is in I have to enjoy opera selections or fashion talks. When daughter has a caller it is generally ballads or jazz. When son is around, he goes DXing. So I generally enjoy what I get—like ordering hash in a restaurant."

Arctic Trading Posts Enjoy American Radio Concerts

THOUGH ice-bound and in darkness through the long winter months, trading posts in the Arctic zone will not be entirely isolated from civilization and life. According to plans made by the Hudson's Bay Company, lonely posts will be provided with radio receiving sets so as to secure entertainment at any time. Two north-bound ships, the S.S. "Bayeskimo" and the S.S. "Nascopie" are carrying Westinghouse radio receiving sets to six of the posts above the Arctic Circle.

In order to determine whether or not these posts will be able to hear the concerts from the United States next winter, the ships are listening in on their way north to the broadcasts as they steam to the frigid zone. Several nights ago, the Westinghouse Station WBZ in Springfield, Mass., gave a special concert at 11 p. m. and radiograms received from the steamship "Bayeskimo" state that the music has been heard with great success.

There are hundreds of posts spread throughout Canada and North America, from above the Arctic Circle into James Bay. The ships have left for these trading posts and the factors will have their sets for next winter. Although the reports received so far from the ships are very encouraging, complete information on the results secured will be obtained upon their return. The posts are so far removed from civilization that this will be the last news from the outposts until spring. The lanes of travel to these posts are entirely blocked on account of the heavy ice which accumulates.

WBZ Fans to Compete for Short Story Prizes

PERSONS who like to write, or who want to learn how, will welcome the announcement from Station WBZ that a course in short story writing will be broadcast at regular intervals.

Dr. J. Berg Esenwein, probably the best known national authority on short story writing, has been chosen by Station WBZ to give the course. Every Thursday evening, at the same hour, and continuing for ten weeks, Dr. Esenwein will give ten separate and complete lectures on the elements of writing, development of plots, climaxes, treatment, etc., which will cover the subject in a most thorough manner.

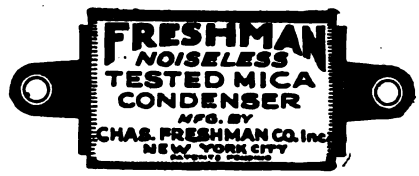
At the conclusion of the course, any person who has been listening to the series of lectures will be eligible to enter the contest of short story writing, for which a first prize of $25, a second and third prize of $15 and $10 respectively will be awarded. Dr. Esenwein will outline briefly, at the beginning of the course the conditions for the contest and fans will listen in carefully, as the stories will have to be written so as to show that the course has been followed.

The introduction of this feature in the program of the Westinghouse station at Springfield, Mass., is an innovation in broadcasting. It is the belief of the station that such a course will accomplish more to justify broadcasting that the miscellaneous talks which have been so current at most stations. The outcome of this experiment is to be watched with interest.

Lakes Radio Bulletins

WEATHER bulletins and hydrographic information will be broadcast twice daily by the Intercity Radio Company, located in Cleveland, on Lake Erie. The service is intended for the shipping on the Great Lakes, and will be broadcast on a wave length of 706 meters, spark. The call of the station is WTK. This station also is licensed to communicate with Rogers City, Mich., on a wave of 1,764 meters.

The Condenser Sensation of Modern Radio



Through the accuracy and dependability of Freshman Condensers, hook-ups and circuits have been perfected which have completely revolutionized the art of Radio Reception.

These little Storers of energy and rectifiers of Radio Current are the very heart of a well-built radio set.

The proper fixed condenser will make all the difference in the world in the reception, clarity and selectivity your set affords.

Capacity	Each	Capacity	Each
.0001	$ .35	.002	$ .40
.00015	.35	.0025	.50
.00015	.35	.003	.60
.0002	.35	.004	.75
.0002	.35	.005	.75
.00015	.35	.006	.75
.0025	.35	.006	1.00
.0006	.40	.01	1.00
.0006	.40	.015	1.50
.001	.40	.02	2.00
.0015	.40	.025	2.50

The FRESHMAN is so designed that constant equal pressure is exerted on the condenser plates over the entire area. They are the only condensers that do this and therefore the only condensers that avoid noises, which are due to variable pressure on the plates.

At your dealers, otherwise send purchase price and you will be supplied postpaid.

Do You Want to Change Your Transmitter or Are You Planning to Build One?

Then you will want these back numbers of Radio World: March 31, A Low Power CW Transmitter, by C. White. April 21, Hams Transmitter, by John Kent (circuit used by 2YE). May 5, Combined CW and Phone Set of M. Bobart, at Radio Central. May 26, A Simple CW or Phone Set That Works. E. W. H. Decker, 2UA. These numbers describe in detail all the various parts, with complete instructions as to how to operate. No up to date amateur should be without them. 15c. a copy. The four copies for 60c. or start your subscription with any number.

Salesmanship Behind the Counter

WHAT does it matter if the manufacturer produces the best goods in the world, if he advertises them under a trademarked name so consistently that they are known from coast to coast, if he puts them on the shelves of practically all the retailers; the spiders will merrily spin webs around them if they are not sold by the retailer—the ultimate salesman. That's why economists, researchers, and investigators on the trail of "cost of distribution" have followed the goods of the world into the retail store and have told the retailer—that is, the average retailer—that his turnover is too low, says Arthur W. Little in "Forbes" Magazine.

In scores of smaller stores in America and particularly in the more progressive smaller retail establishments in the Middle and Far West, the investigator finds little classes in salesmanship established by the proprietors and conducted by methods similar to the training methods of the metropolitan stores. Sales forces assemble in the stores in the evenings and study merchandise analysis and stage mock sales.

Often these evening sessions are addressed by the traveling salesmen of concerns from whom the stores buy goods. Manufacturers and wholesalers whose products are marketed by retail stores are training their salesmen in all branches of retail merchandising; these road men often are former retail salesmen; they know how to sell and they go out into their territories with orders from headquarters to impart their knowledge of salesmanship to their customers.

In Lawrence, Kansas, is the store of a retail clothier who, among clothiers everywhere, is considered a big-league merchandiser.

"Listen" this man confided to me, "the best source in the world for selling ammunition is the traveling salesman. Me? I never buy a bill of goods that I don't demand, along with the goods, enough information about them to sell them. When I put in a new line, I kidnap the salesman. Then I call my own men together and say to them, 'Boys, this fellow here just sold me some goods, and he gave me a danged good selling talk about them. Now I'm going to ask him to repeat that talk to you. I want you to make notes and ask questions; so that when the goods come in, you can sell them.'"

Radio Penetrates Grand Canyon

THE Geological Survey party carrying a radio set on a trip through the Grand Canyon of the Colorado, has arrived safely at Bright Angel trail. Notwithstanding the predictions of experts that it would be impossible to receive radio messages while in the bottom of Grand Canyon, Colonel Birdseye reports that he is in daily receipt of messages broadcast from Los Angeles, Salt Lake and Chicago. He received the news of President Harding's death within 45 minutes after it occurred. Reports of his progress will be sent out for broadcasting when he reached Basstrail about September 10, Supai Creek September 20 and Diamond Creek October 15.

BIG ADVERTISING VALUE IN RADIO WORLD'S FALL BUYERS' NUMBER

1 At four dollars an inch (yearly contract rate) 74,000 radio-buying readers learn of your goods—a greater number of eyes than four dollars can reach in any other radio advertising medium.

2 Radio World gives **quicker results**—i. e., advertising copy received by Thursday p. m. is published and on the news-stands the following Wednesday morning.

3 A Weekly has greater **reader interest**—the Saturday Evening Post, Literary Digest, Iron Age, are Weeklies. Radio World, the big success of radio, is published every week.

4 Advertising is a gamble. Life itself is. A gambler bets his money on past performances. Radio Corporation of America tried out **Radio World,** then gave us a yearly contract. Magnavox tried us for small space thirteen times, and have just renewed for fifty-two times, using pages. The Federal Telephone & Telegraph Company investigated us from every angle for weeks, then gave us a fifty-two consecutive issue order. A four-time trial of Radio World almost invariably ends with a fifty-two time contract at $120 per page net or $4.00 an inch.

DIAGRAMS AND DESCRIPTIVE MATTER ABOUT THE LATEST ARMSTRONG, FLEWELLING, REINARTZ AND OTHER FAMOUS CIRCUITS, together with other special features, will make **Radio World's** FALL BUYERS' NUMBER a great cash producer for advertisers.

DATE OF THIS IMPORTANT ISSUE—OCTOBER 6

(LAST BLACK FORM CLOSES SEPTEMBER 27)

Special service and value to advertisers in Radio World's **FALL BUYERS' NUMBER:** All advertisers who give us copy for quarter page or more space in Radio World's **FALL BUYERS' NUMBER** will, on request, have their announcements appear in **two colors at the price of one**—in case copy is in our hands by September 24.

Write, wire or phone now for special positions
